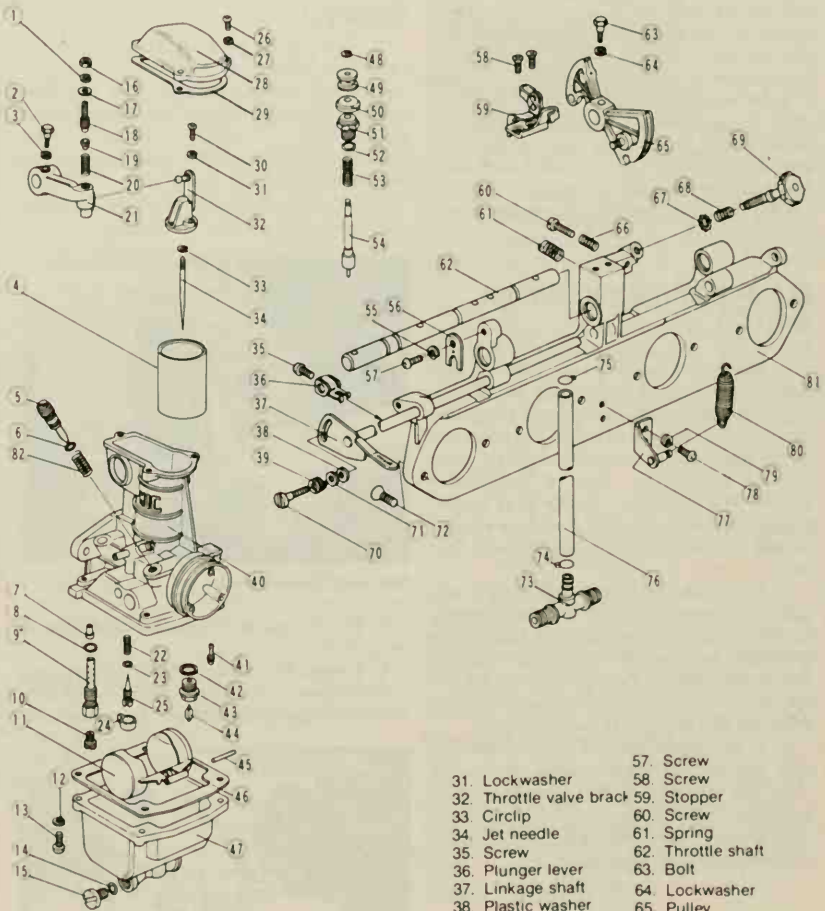
Removing the throttle slide assembly

3. If desired, remove the two screws inside the throttle valve(s) and take out the jet needle. Note the position of the needle clip. Do not change the position of the clip unless tuning adjustments are being made.
4. On early model carburetors, remove the pilot fuel screw extenders and unscrew and remove the pilot screw, o-ring and spring. On later model carburetors, unscrew and remove the pilot air screw, spring, and o-ring from the carburetor body.
5. Unscrew and remove the float bowl screws and carefully remove the float bowl and float bowl gasket.

Float bowl components

6. Unscrew and remove the main jet, air bleed pipe, and pilot jet.
7. Push out the float pin and remove the float assembly.
8. Remove the float needle. Unscrew and remove the float needle seat and gasket.
9. If the carburetors have been removed from their mounting plate, unscrew and remove the starter plunger after first removing the plunger cap.
10. From the top of the carburetor, push out the needle jet using a soft wooden dowel or the like.

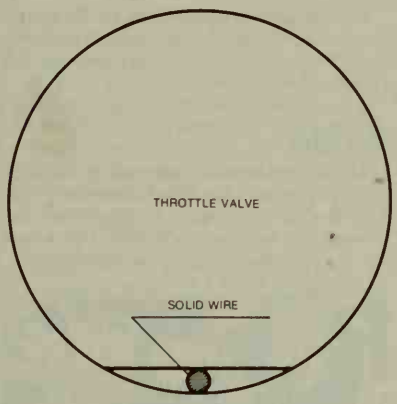
Assembly



1. Assembly is basically the reverse of disassembly. Note the following points:
2. Check the condition of all gaskets and o-rings and replace them if they are damaged.
3. Be sure that the jet needle clip is in the 4th groove from the top, unless tuning changes were made.
4. Do not overtighten the fuel jets when installing them in the carburetor body.
5. When installing the pilot fuel screws on early model carburetors, screw them in until they are lightly seated, then back each one out 1⅛ turn. Fit the plastic extender with the projection facing the front. When installing pilot air screws to the carburetor bodies on later model carburetors, screw them in until they are lightly seated, then back each one out two full turns.

The pilot screws may have to be readjusted after the carburetors are installed.

6. Perform a mechanical synchronization of the carburetors (see below).
7. After installing the carburetors, make sure that all fuel lines are secure. Turn on the gas and allow the units to sit for a few minutes before operating the motorcycle to check for leaks.



Mechanical Synchronization

Any time the carburetors have been disassembled, it is wise to perform a preliminary mechanical synchronization prior to installation. After installation, the carburetors should

Carburetor assembly

Bottom of Carburetor Bore

Throttle slide mechanical synchronization

Adjusting the throttle slides

be synchronized with vacuum gauges as outlined in the "Tune-Up" section.

1. Remove the carburetor top covers and loosen the throttle slide adjusting screw locknuts.
2. Taking each carburetor in turn, insert a piece of 0.5–1.0 mm solid wire between the throttle slide and the bottom of the bore. If necessary, turn the adjusting screw so that the wire is trapped. Then, holding the carburetors upside down, slowly turn the adjusting screw to raise the throttle slide until the wire just falls out. Tighten the locknut. Repeat the procedure with each locknut. This will ensure that the throttle slides are at least close to being synchronized, thus simpifying vacuum gauge usage.

CARBURETOR OVERHAUL (750)

Removal

1. Remove the gas tank. Remove the left and right side covers.
2. Loosen the carburetor clamp screws. Slide the manifold spring bands to one side.
3. Slide the clamps up and pull the vacuum lines off the carburetors.
4. Loosen the locknuts of the throttle cable adjuster, and free the adjuster from the bracket.
5. Disconnect the overflow tubes from the air cleaner box.
6. Pull the carburetors out and to the right, disconnecting the cable end from the pulley as soon as it becomes accessible.

Installation

Installation is basically the reverse of removal. Note the following points:

1. Install the carb clamps so that the one for carb No. 2 has the opening pointing upwards, and that the others point downwards.
2. Run the throttle cable between the right fork leg and the head pipe, and the right side of the frame top tube.
3. Adjust the throttle cable.

Separation

The throttle slide assembly and the float bowl components and jets are removable without separating the carburetors. If, however, this procedure is desired, it is as follows:

1. Obtain a choke shaft kit prior to separation. It is essential for the assembly procedure.
2. Unhook the end of the choke link spring from the lever on the right choke shaft.
3. Remove the screws and lockwashers and take off the upper mounting plate.
4. Remove the lower mounting plate in the same way, and separate the left and right carburetor pairs.
5. To separate units Nos. 1 and 2, straighten the flat washer and remove the nut, washer, lockwasher, and choke lever.
6. Remove the bolt, wave washer, flat washer, and plastic washer, and pull off the choke linkage shaft. The small steel ball and spring come off with the shaft.
7. Remove the choke valve retaining screws and remove the choke valves.
8. Pull off the choke shaft.

Assembly

1. Assembly is the reverse of disassembly. Note the following points:
2. When installing the choke valve, a new choke shaft and screws must be used. Crimp the screws after installation with the adapter in the kit and a pair of pliers.
3. Check that the o-rings are in place, and install the long pipe of the fuel three-way joint to the No. 3 carb. Install the linkage spring.
4. Hook the end of the choke link spring on the lever.
5. The centerlines of the carburetor bores must be parallel both horizontally and vertically. If not, loosen the mounting screws and align the carburetors. Then retighten the screws.

Disassembly

The major components of each carburetor can be serviced without separating the assembly.

1. Remove the throttle slide cover screws and take off the cover and spring. Carefully pull out the throttle slide assembly.
2. If removal of the needle is desired, unscrew the holder.
3. To remove the pilot screw, punch and pry off the plug. Turn the pilot screw in carefully until it is fully seated, counting the number of turns. The screw must be reset to this number on assembly. The screw should be only lightly seated. Do not attempt to tighten it with undue force.
4. Remove the float bowl screws and carefully take off the float bowl.
5. Remove the primary main jet, bleed pipe, secondary main jet, and needle jet holder. All items unscrew.
6. Push out the float pivot pin and remove the floats and float needle.
7. Push out the needle jet from the carburetor mouth.
8. Remove the plastic plug and unscrew the pilot jet beneath it.

Assembly

Assembly is straightforward. Note the following points:

1. Be sure that the slide diaphragm is correctly installed. The diaphragm is located with a tab. The lip must be seated in its groove all the way around. The slide must move up and down with light finger pressure.
2. Fit the pilot screw by screwing it in until lightly seated as on disassembly, then backing it off the same number of turns you counted in the disassembly procedure.
3. Use a new pilot screw plug and bond it in place.

Fast Idle Adjustment

1. Check that there is 4–6 mm (0.16–0.24 in.) clearance between the pin on the idling link and the fast idle cam when the choke lever is fully pushed down.

ELECTRICAL SYSTEM

NOTE: *The charging system may be one of two types. The early type used separate regulator and rectifier, the regulator being the mechanical type. The later system has an integral regulator/rectifier unit.*

Determine the system in use before beginning tests, then refer to the appropriate section.

CHARGING SYSTEM (EARLY)

Alternator Output Test

1. Before attempting this test, check the condition of the battery. If the battery charge

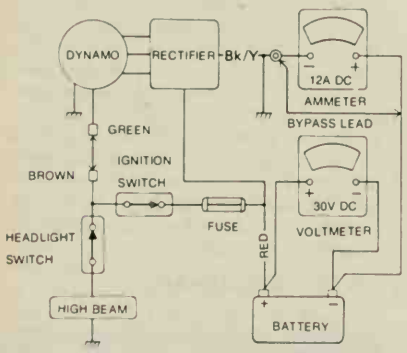
is less than 12 v, charge the battery. If a full charge cannot be obtained, the battery should be replaced.

2. Carry out the test with the engine at operating temperature.

3. Remove the left side cover.

4. Be sure that the ignition switch is turned off.



5. Disconnect the regulator green and brown leads from the regulator. Connect these two leads together.

Disconnecting the regulator leads

NOTE: *When connecting the two leads be sure that the connection is not grounded. Do not leave the two leads connected any longer than is necessary. Be sure that they are disconnected immediately after the test is carried out.*

6. Open the seat and disconnect the battery negative lead from the battery terminal.

Circuit diagram for alternator output test

7. Connect an ammeter in series with the battery, connecting the meter negative lead to the battery negative lead and the meter positive lead to the battery negative terminal.

8. To avoid damage to the meter during the test, connect a by-pass wire to the battery negative terminal and the meter negative lead.

9. Connect a DC voltmeter (at least 30v DC) across the battery.

10. Start the engine with the kickstarter.

CAUTION: *Do not use the electric starter to start the engine as this may cause damage to the ammeter. Make sure that all connections are tight. A loose connection may damage electrical components.*

11. Turn on the headlight and set it to high beam.

12. Disconnect one end of the by-pass lead.

13. Run the engine at 4,000 rpm, and note the meter readings. They should be as follows:

a. The voltmeter should read 15 v.

b. The ammeter should read about 3 amps.

14. If either reading is somewhat lower than these figures, check the field coil and armature resistance as outlined below.

Alternator Test

1. In the event that the measured output of the alternator is not with specification, the armature windings and field coil windings should be checked for shorts or open circuits. This can be done with an ohmmeter.

2. Disconnect the 4-pin electrical connector on the electrical panel.

Checking armature windings for continuity

3. With the ohmmeter set on the R x 1 range, check the resistance between each of the three yellow leads in turn. In each case, resistance should be 0.4–0.6 ohms. If resistance is greater than this, there is probably an open circuit and the armature must be replaced. If resistance is zero, there is probably a short in the system, and, again, the armature must be replaced.

4. Using the highest range on the ohmmeter, measure the resistance between each of the three yellow leads in turn and a ground on the chassis. Resistance should be infinite. If there is any reading short of this, the armature must be replaced.

5. Disconnect the green field coil wire and measure the resistance between the wire and ground on the chassis. Field coil resistance should be 2.7–3.4 ohms. If the resistance reading is not within this specification, the field coil must be replaced.

Removal

1. To remove the alternator, remove the left side cover and disconnect the alternator 4-pin connector and the green lead.

2. Remove the engine sprocket cover.

3. Disconnect the neutral indicator switch lead and pull out the wiring towards the left side.

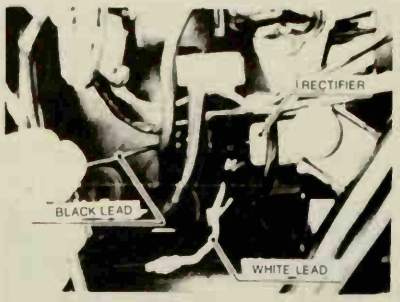
4. Remove the four alternator cover screws and remove the cover and gasket.

5. Remove the armature allen bolts to remove the armature from the cover; remove the three field coil allen bolts to remove the field coil.

Installation

1. Apply a liquid gasket compound around each of the armature grommets before fitting.

2. Use a non-permanent thread-locking compound on the allen bolts.



3. When installing the alternator cover, be sure that the two knock pins are in place. Use a new gasket.

4. Arrange the wiring between the crankcase and the external shift mechanism cover.

5. The remainder of the procedure is the reverse of removal.

Rectifier

1. With the ingition switch off, remove the left side cover. Disconnect the white lead from the battery positive terminal, and disconnect the rectifier black lead. Disconnect the 4-pin connector on the electrical panel.

Checking the rectifier

2. Using the R x 10 or the R x 100 range on the ohmmeter, check the resistance in both directions between the white lead and each yellow lead, and then between the black lead and each yellow lead. In each case, resistance should be low in one direction, and approximately ten times as high in the opposite direction.

3. If any check indicates that resistance is high in both directions, or low in both directions, the rectifier is defective and must be replaced.

Regulator

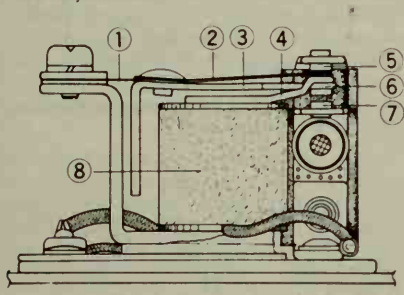
1. The regulator should be checked if the battery overcharges or discharges. If this happens, check the battery first, before attempting any regulator tests. These tests will not be accurate if the battery is defective or is not fully charged.

2. Other symptoms of a defective regulator include bulbs burning out at high rpm, or the need to constantly add water to all of the battery cells.

3. Remove the headlight and disconnect the 9-pin connector therein. Turn the ignition switch *on*, and be sure that all lights are turned *off*.

4. Connect a DC voltmeter (at least 30v scale) across the battery. Start the engine and run it at 1,600 rpm. The voltage reading should be 14–15 v.

5. Gradually increase engine speed and recheck the meter reading with the engine running at 4,000 rpm. The reading should still be 14–15 v.



NOTE: *Engine speed must increase directly from 1,600 rpm to 4,000, and must not decrease at any point during this time. If engine speed is allowed to drop, the readings may be incorrect. If this happens, start the test over from the beginning.*

6. If the voltage reading is 14–15 v in both cases, the regulator is satisfactory. If it was not, test the regulator as outlined below.

NOTE: *If the motorcycle is still under warranty, replace the regulator at this point rather than carrying out the following tests.*

7. Remove the left side cover and disconnect the black, green, and brown leads from the regulator.

8. With an ohmmeter, check the resistance across the middle and upper terminals with the points P_0 in position 1. There should be zero resistance. If there is any resistance indicated, the points are probably dirty and should be cleaned with emery cloth and/or a non-oily solvent.

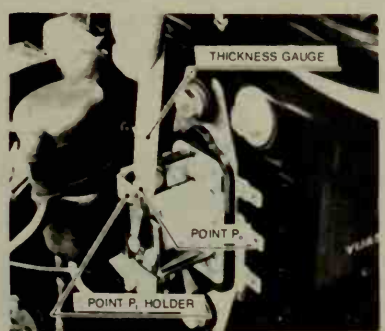
4. Adjuster Arm
5. Point P_1
6. Point P_0
7. Point P_2
8. Relay Coil

Voltage regulator components

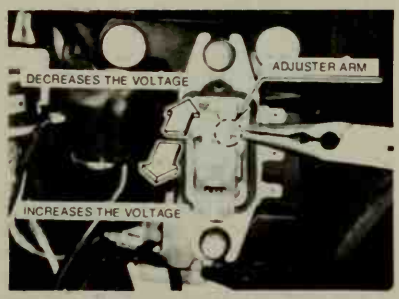
9. With the points in position 2, resistance should be 9 ohms. If resistance is not correct, the regulator must be replaced.



10. Connect the ohmmeter across the middle and lower terminals. In position 1, the resistance reading should be about 100 ohms. If the reading is not correct, the regulator must be replaced. In position 2, resistance should be zero. If it is greater than this, the points are probably dirty and should be cleaned with emery cloth and a non-oily solvent.

11. If cleaning the points does not get resistance down to zero ohms, replace the regulator.

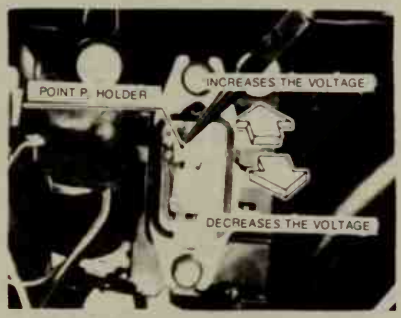
12. Press down on the armature and check the armature gap with a feeler gauge. It should be 0.3 mm (0.012 in.) or more. If the gap is not correct, bend the holder for point P_2 until it is.



Checking armature gap

Checking the gap between points P_2 and P_0

13. Check the gap between points P_2 and P_0 with a feeler gauge. The gap should be 0.30–0.45 mm (0.012–0.018 in.). If the gap is incorrect, bend the holder for point P_1 to correct it.



14. Connect a DC voltmeter across the battery terminals and start the engine, noting the voltage at various engine speeds. If the voltage was not between 14–15 volts, adjust the output by bending the adjuster arm. Bending the arm up increases the voltage output, and bending it down decreases it.

Bending the adjuster arm to alter voltage output

15. Start the engine and read the voltage with the engine running below 1,600 rpm. It should be 14–15 v. If the voltage is too low, bend the adjuster arm up. If it was too high, bend the arm down. Be sure the ignition is *off* when making these adjustments.

16. Check the voltage with the engine running at 4,000 rpm. If it is less than the specified 14–15 v, bend the holder for point P_2 down. If it is greater, bend the P_2 holder up.

Bending the P_2 holder to alter voltage output

17. Fit the regulator cover and recheck voltage output.

CHARGING SYSTEM (LATE)

System Check

1. Always check battery condition and state-of-charge before beginning system tests or suspecting failure of the other components.

2. The battery must be in good condition and fully charged before carrying any other tests or the results may be incorrect.

3. Connect a DC voltmeter across the battery terminals. With the engine running at 4,000 rpm, the reading should be about 14.5 v.

If the reading is higher than this value, the rectifier/regulator is defective. If lower, check the alternator and the regulator/rectifier.

Alternator Test

1. Remove the engine sprocket cover and disconnect the three yellow leads.

2. With an AC voltmeter set on the 250 v range, check the voltage across pairs of the yellow leads with the engine running at about 4,000 rpm. This no-load test should give about 50 v across each pair of leads.

3. A static alternator coil test can be carried out with an ohmmeter. Resistance across each pair of yellow leads should be 0.48–0.72 ohms.

If the resistance is infinite, the wiring has an open circuit. If lower, there is a short. In either case, the stator must be replaced.

4. With the ohmmeter set on the highest scale, check resistance between each yellow lead and the stator core. Resistance must be infinite in each case.

5. If the ohmmeter tests indicate normal resistance, but the no-load test (Step 2) indicates low voltage output, the rotor magnets may be weakened. Replacement of the rotor is the solution.

Regulator/Rectifier

1. Remove the electrical panel beneath the left side cover.

2. Disconnect the white/red lead and 6-pin connector.

3. With an ohmmeter set to the 10 or 100 ohm range, check the resistance in both directions between the white/red lead and each yellow lead in turn, then between the black lead and each yellow lead. The resistance must be low in one direction, but high when the test leads are reversed. If resistance shows low or high in both directions, the unit must be replaced.

4. The easiest and most foolproof check of the regulator side of the regulator/rectifier unit is by replacement with a new unit.

BREAKER POINT IGNITION

The ignition system consists of the battery, breaker points, coils, condensers, spark plug caps, and spark plugs.

There are two sets of breaker points and two ignition coils. Each coil fires two cylinders. They are paired No. 1 and 4, and No. 2 and 3.

1. In the event of failure of the ignition system, first check the fuses; if all are in working order, check that the snap connectors for the coils and breaker points are all clean and tight.

2. At this point refer to chapters 2 and 3 for inspection procedures for the breaker points, plugs, and battery. If these items are all in working order, the problem may be isolated to the coils, condensers, or plug caps.

3. If only one cylinder fails to fire, and the problem is not a loose connection or defective spark plug, suspect the plug cap. The caps are fitted with a resistor to prevent radio interference while in operation, and heat and vibration may cause the value of this resistor to increase considerably, even to becoming an open circuit.

The easiest way to see if a misfire is due to a defective cap is to switch the plug lead of the non-firing cylinder with its corresponding cylinder (1–4, 2–3). If the dead cylinder begins

to fire and the other cylinder ceases, the problem is the plug cap. The caps should be replaced as a set.

Functional caps will have a resistance of 5,000–7,500 ohms. Usually, when resistance reaches about 9,000 ohms, the plug for that cap will no longer fire.

Caps are easily removable by unscrewing them from their cables.

4. Defective condensers are seldom a problem, since these are now usually replaced along with the breaker points. Defective condensers will cause considerable arcing or sparking between the breaker point contacts while the machine is running, and this should be cause for replacement before they fail completely. Badly burned or pitted point contact surfaces can also be caused by defective condensers, as well as by improper adjustment. If the points are in bad condition, replace them and the condensers as well.

5. Condenser capacity can be checked with electrical test equipment (if available) in place on the machine, provided the condenser is first disconnected from the primary terminal. Capacitance should be 0.24 MFD. The resistance of the condensers should be in excess of 10 MΩ. A variation of 10% in either reading is allowable.

6. Coils should really be checked on a Kawasaki Electrotester, where a good coil should be able to produce a 6 mm (0.24 in.) spark. If this is not available, however, some clue to coil condition (although not necessarily as conclusive) can be gained by measuring the resistance of the primary and secondary windings with an ohmmeter.

7. With the ohmmeter set to the R x 1 range, check the resistance between the coil yellow/red lead and the green or black lead. Resistance of the primary winding should be about 4 ohms. If less, the winding is shorted; if greater, there is an open circuit. In either case the coil must be replaced.

8. To check secondary winding resistance, check the resistance between the two spark plug leads using the R x 100 scale. Resistance should be about 23K ohms. If resistance is somewhat less than this amount, it is probable that the coil winding has started to break down; if resistance is greater, there is an open circuit. In either case the coil should be replaced.

9. Using the highest available ohmmeter range, check for resistance between the yellow/red lead and the coil core and between one of the spark plug leads and the core. Resistance in each case should be infinite. If there is any reading, replace the coil.

10. Check the condition of the spark plug leads and replace the coil if the leads are in any way damaged.

Checking secondary winding resistance

ELECTRONIC IGNITION

Ignition Coils

1. The most reliable check of ignition coil condition is carried out on a Kawasaki Electrotester if available. The coils should be able to produce a 7 mm arc.

If an Electrotester is not available, check the coils with an ohmmeter as follows.

2. Remove the spark plug caps. Connect the ohmmeter across each pair of spark plug leads. This checks the secondary winding resistance which should be 12–18 K ohms.

3. Disconnect the low tension leads from the coil and check resistance across the coil's low tension terminals. It should be 1.8–2.7 ohms.

If both resistance checks are not within specification, the coil must be replaced.

Pick-Up Coils

1. Check the resistance between the black lead and the blue lead and between the yellow lead and red lead. In both cases, resistance should be 360–540 ohms.

2. Check resistance between each lead and ground on the engine using the meter's highest scale. Resistance must be infinite.

3. If any resistance readings are not within these specifications, the pick-up coil(s) are defective.

IC Igniter

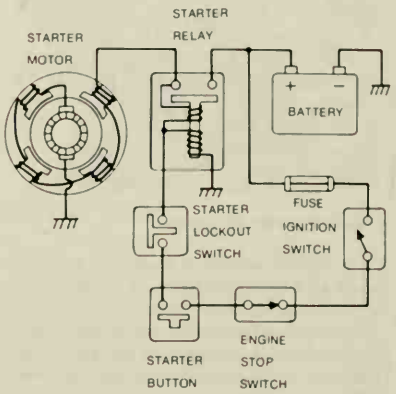
Check the IC Igniter circuitry with an ohmmeter according to the accompanying chart. Replace the unit if all meter readings are not in accordance with the chart.

Resistance readings are measured on the Kawasaki Hand Tester and may vary if another instrument is used. However, they should be consistent in any case.

STARTING SYSTEM

The starting system consists of the starter motor and clutch, the solenoid, the handlebar-mounted starter button, and clutch-operated lockout switch, which prevents starter operation unless the clutch is disengaged.

When the clutch lever is pulled in, and the starter button is pushed, battery current activates the starter solenoid, sending current directly from the battery to the starter motor and turning the engine over.



The starting system is quite reliable and it is unlikely that major problems will arise.

Testing

1. If the starter motor spins, but the engine does not, suspect the starter motor clutch.

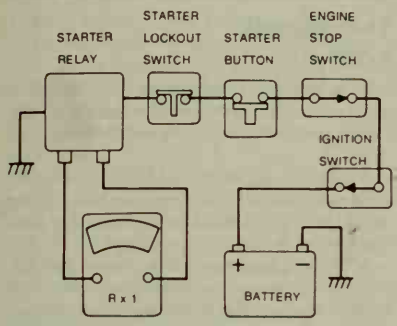
2. If the engine turns over very slowly, the problem may be a low battery, too thick oil usually caused by extremely low temperatures, or a defective starter motor.

3. If the engine does not turn over at all, turn on the headlight, pull in the clutch, and hit the starter button. If the headlight retains its brightness, the starter motor is not drawing current, and the trouble may be confined to the starter button, lockout switch, wiring and wiring connections, or a defective starter motor solenoid. If the headlight dims, this indicates that the motor is drawing current, and the trouble may be a low battery or a defective starter motor. Check the battery as outlined in Chapter 2, "Maintenance."

Starter motor circuit

Solenoid Test

1. Disconnect the two high-tension leads from the starter solenoid and connect an ohmmeter set to the R x 1 scale across the terminals.



2. With the ignition switch on, pull in the clutch and hit the starter button. The ohmmeter should read zero ohms. The solenoid should make a clicking sound as well. If a click is heard, but resistance does not read zero, the solenoid is defective and must be replaced.

3. Disconnect the two low-tension solenoid leads (black and yellow/red) and measure the resistance across them. It should be close to zero ohms. If it is not, the solenoid is defective and must be replaced.

4. If the solenoid checks out according to the above tests, but still will not work, check that it is getting current by connecting a 30v DC voltmeter across the black and yellow/red leads from the wiring harness. Pull the clutch

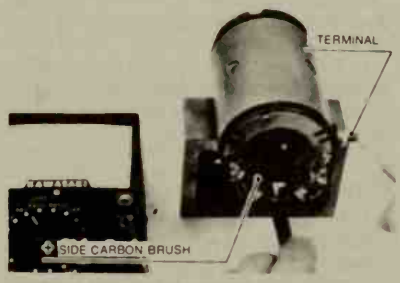
Checking the relay (solenoid)

lever and hit the starter button. The ignition switch must, of course, be on. The voltmeter should read battery voltage, indicating that the solenoid is getting current. If the meter reads zero volts, suspect the starter button, lockout switch, or wiring connections.

Starter Motor Tests

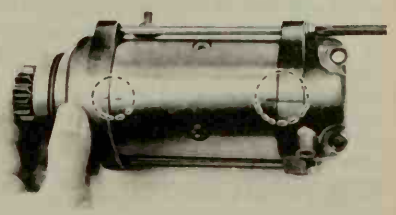
REMOVAL AND INSTALLATION

1. Remove the engine sprocket cover.
2. Remove the left side cover.
3. Disconnect the starter motor lead from the solenoid.
4. Remove the two starter motor retaining bolts, and remove the starter motor.
5. Installation is the reverse of removal. Be sure that the starter motor mounts are clean (this is an electrical ground) and that the starter motor o-ring is in good condition.



INSPECTION

1. The starter motor can be disassembled after removing the two long screws and separating the components.
2. Check carbon brush length. Standard brush length is 12–13 mm (0.47–0.51 in.). The brushes must be replaced if their measured length is less than 6 mm (0.24 in.).
3. Brush springs should be checked. Spring tension should be 560–680 gr, but they may be considered serviceable if they will hold the brushes firmly in place.
4. Clean the commutator surface thoroughly and polish it with fine emery cloth. Check mica undercut depth. Standard depth is 0.5–0.8 mm (0.020–0.032 in.). The armature should be replaced if the depth is less than 0.2 mm (0.008 in.).
5. Measure the resistance between each of the commutator segments using the lowest ohmmeter scale. Resistance should be zero. If any of the tests shows resistance, the windings may be open and the armature must be replaced.



Checking for continuity between the commutator segments

6. Using the highest ohmmeter range, measure the resistance between the commutator and the armature shaft. Resistance must be infinite. Any reading indicates a short and necessitates replacing the armature.
7. To check the field coils, measure the resistance between the starter motor terminal and the positive side carbon brush. Resistance must be close to zero. If it is not, there may be an open circuit in the field coils and the yoke assembly must be replaced.

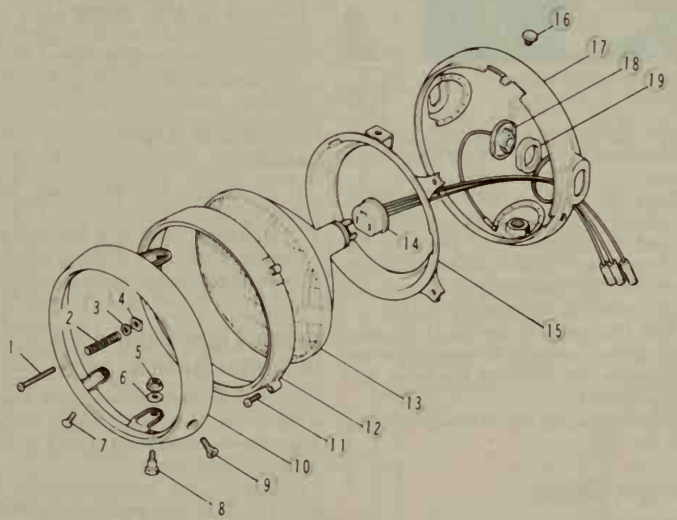
Checking for field coil continuity

8. Using the highest meter scale, measure the resistance between the positive side brush and the starter motor body. Resistance must be infinite. If there is continuity, this indicates a short in the field coils, and the yoke assembly must be replaced.
9. To check the starter clutch, turn the idler gear by hand. When viewed from the left side of the engine, the idler gear should turn counterclockwise freely, but should not turn clockwise. If operation is not correct, disassemble the starter clutch and check for worn or damaged parts.
10. When assembling the starter motor, align the notch on the end plate with the tongue on the housing, and align the mark on the end covers with the lines on the housing.

When assembling the starter motor, align the marks

Starter Lockout Switch

1. Remove the gas tank. Disconnect the two lockout switch black leads.
2. Connect an ohmmeter set to the R x 1 scale across the switch leads and pull in the clutch lever. The meter should read zero ohms. If it does not, the switch is defective and must be replaced.



HEADLIGHT

Removal

1. Remove the two retaining screws and pull the headlight out of the shell.
2. Disconnect the socket from the headlight.
3. Remove the pivot screws and nuts. Remove the rubber dampers.
4. Remove the beam horizontal adjusting screw. A nut, spring seat, and spring will come off as well.
5. Separate the outer and inner rims.
6. Remove the two screws to separate the beam unit from the inner rim and mounting rim.

Installation

1. Install the sealed beam unit in the mounting rim fitting the raised portion into

2. Note that the spring seat on the horizontal adjusting screw goes between the spring and the bracket.

3. Adjust the horizontal beam after installation.

ELECTRICAL SWITCHES

Switches can be checked with an ohmmeter or a continuity light. In all cases, check the appropriate bulbs first.

Ignition Switch

KZ650-B

1. Disconnect the 4-pin connector inside the headlight shell.

2. With the ignition switch in the "off" position, there should not be continuity between any of the wires.

3. With the ignition switch in the "on" position, there should be continuity between the white and brown wires, and between the blue and the red wires.

4. In the "park" position, there should be continuity between the white and the red wires.

5. If the swtich fails any of the above tests, replace it.

KZ650-C/D AND LATER, KZ750

1. Disconnect the 6-pin connector inside the headlight shell.

Checking the ignition switch

2. With the switch in the "off" position, there should not be continuity between any of the wires.

3. With the switch in the "on" position, there should be continuity between the white and brown wires (or between the white, brown, and yellow on later models), between the blue and red wires, and between the white and orange/green wires.

4. With the switch in the "park" position, there should be continuity between the white and red wires and between the white and orange/green wires.

5. If the switch fails any of the above tests, replace it.

Headlight Switch

KZ650-B

1. Remove the gas tank. Disconnect the brown, blue/white, and brown/white leads going to the switch.

2. With the switch "off," there should be no continuity.

3. With the switch "on," there should be continuity between all three leads.

4. If the switch fails the test, disassemble it and clean the contacts. If this fails to restore normal operation, the switch should be replaced.

KZ650-C/D

1. Remove the gas tank. Disconnect the brown, brown/white, and blue/white leads going to the switch.

2. With the switch in the "off" position, there should be continuity between the brown/white and the blue/white leads.

3. With the switch in the "on" position, there should be continuity between all three leads.

4. If the switch fails the test, disassemble it and clean the contacts. If this fails to restore normal operation, the switch should be replaced.

Dimmer Switch

1. Remove the gas tank. Disconnect the red/black, blue, and red/yellow leads from the switch.

2. With the switch in the "hi" position, there should be continuity between the red/black and the blue leads.

3. With the switch in the "low" position, there should be continuity between the blue and the red/yellow leads.

4. If the switch fails to operate normally, disassemble it and clean the contacts. If this does not restore proper operation, replace the switch.

Front Brake Light Switch

1. Disconnect the wires and check for continuity across the switch terminals when the brake lever is pulled. If there is no continuity, replace the switch.

CAUTION: *When removing the switch, be careful of spilled brake fluid. Use a non-permanent thread-locking compound on the switch threads, but keep it away from the lower fourth of the threads to avoid contaminating the brake fluid. Bleed the system after installing the new switch.*

Rear Brake Light Switch

1. Disconnect the two leads from the switch.

2. Check for continuity between the two switch leads when the pedal is depressed. If there is no continuity, replace the switch.

Brake Light Failure Indicator Switch

1. Turn on the ignition. Apply and release either brake. The indicator light should go on when the brake light does, and go off when the brake light does.

2. Remove the brake light bulb. The indicator bulb should go on when the brake is applied, and it should flash when the brake is released.

3. If the brake light failure indicator switch does not behave in the prescribed manner, check all wiring connections. If they are sound, replace switch.

Turn Signals

KZ650-B

1. If both left and right turn signals fail to come on at all, first check the battery. If the battery is satisfactory, proceed to check the relay.

2. Disconnect the relay leads and check for continuity across the terminals. Resistance should be zero. If resistance is more than this, replace the relay.

3. If the relay is satisfactory, use a 30 v DC voltmeter, connecting the positive meter lead to the brown relay lead and the negative meter lead to the orange relay lead. With the ignition switch "on," turn the turn signal switch to the "R" and "L" positions. The voltmeter should read battery voltage in either position. If it does not, check the wiring connections, fuse, or ignition switch. If battery voltage is read, but the turn signals still do not work, check all writing connection.

4. If the left and right turn signals do come on, but will not flash or flash very slowly, first check that the battery is not low. Check that all wiring connections are clean and tight. Check that all of the turn signal bulbs are the correct wattage. If all of these are correct, replace the relay.

5. If one light on one side comes on and will not blink, either the other light on that side is burned out or is not the correct wattage, or the wiring is broken or improperly connected.

6. If neither light on one side comes on, both bulbs on that side are burned out, or the turn signal switch is defective.

7. If the turn signal bulbs flash too quickly, and this occurs on one side only, the bulbs on that side are of too high a wattage. If both sides flash too quickly, it may indicate that the battery is being overcharged (check the voltage regulator), or that the turn signal relay is defective.

KZ650-C/D AND LATER

1. If neither the left nor the right turn signals come on at all, check that battery voltage is normal.

2. Remove the left side cover. Disconnect the brown lead and the relay diode from the turn signal relay and check for continuity between the relay terminals. Resistance should be zero ohms. If there is any resistance noted, replace the relay.

3. If the relay is satisfactory, disconnect the relay diode from the orange lead. Set the ohmmeter to the R x 10 or R x 100 range. Check for resistance in both directions across the diode. Resistance should be relatively low in one direction. If resistance is low or high in both directions, replace the diode.

4. If both relay and diode are satisfactory, use a 20v DC voltmeter and connect the positive meter lead to the brown relay lead, and the negative meter lead to the orange lead. With the ignition switch on and the hazard switch off, turn the turn signal indicator switch to the "R" and "L" positions. In each case, the meter should indicate battery voltage. If it does not, check the fuse, the ignition switch, and the wiring. If battery voltage is obtained, but the turn signals will still not work, check all wiring connections.

5. If both left and right turn signals come and stay on or flash slowly, check that battery voltage is normal. Check all wiring connections. Check that the turn signal and indicator

bulbs are of the correct wattage. If all of the above points are correct, replace the relay.

6. If one light on one side comes on and will not blink, either the other light on that side is burned out or is not the correct wattage, or the wiring is broken or improperly connected.

7. If neither light on one side comes on, both bulbs on that side are burned out, or the turn signal switch is defective.

8. If the turn signal bulbs flash too quickly, and this occurs on one side only, the bulbs on that side are of too high a wattage. If both sides flash too quickly, it may indicate that the battery is being overcharged (check the voltage regulator), or that the turn signal relay is defective.

Hazard Circuit

1. If failure occurs, first check the ignition switch and turn signal circuits as outlined above.

2. Remove the gas tank. Disconnect the grey and green hazard switch leads.

3. Set a DC voltmeter to the 20v range, and connect the positive meter lead to the grey lead from the left switch housing, and the negative meter lead to the other grey lead. With the hazard switch on, and the turn signal switch off, turn the ignition switch to the "on" and then to the "park" positions. The meter should read battery voltage.

4. Connect the voltmeter to the green lead and repeat the test. The same result should be obtained.

5. If battery voltage is not obtained, the fuse, hazard switch or wiring connections are at fault.

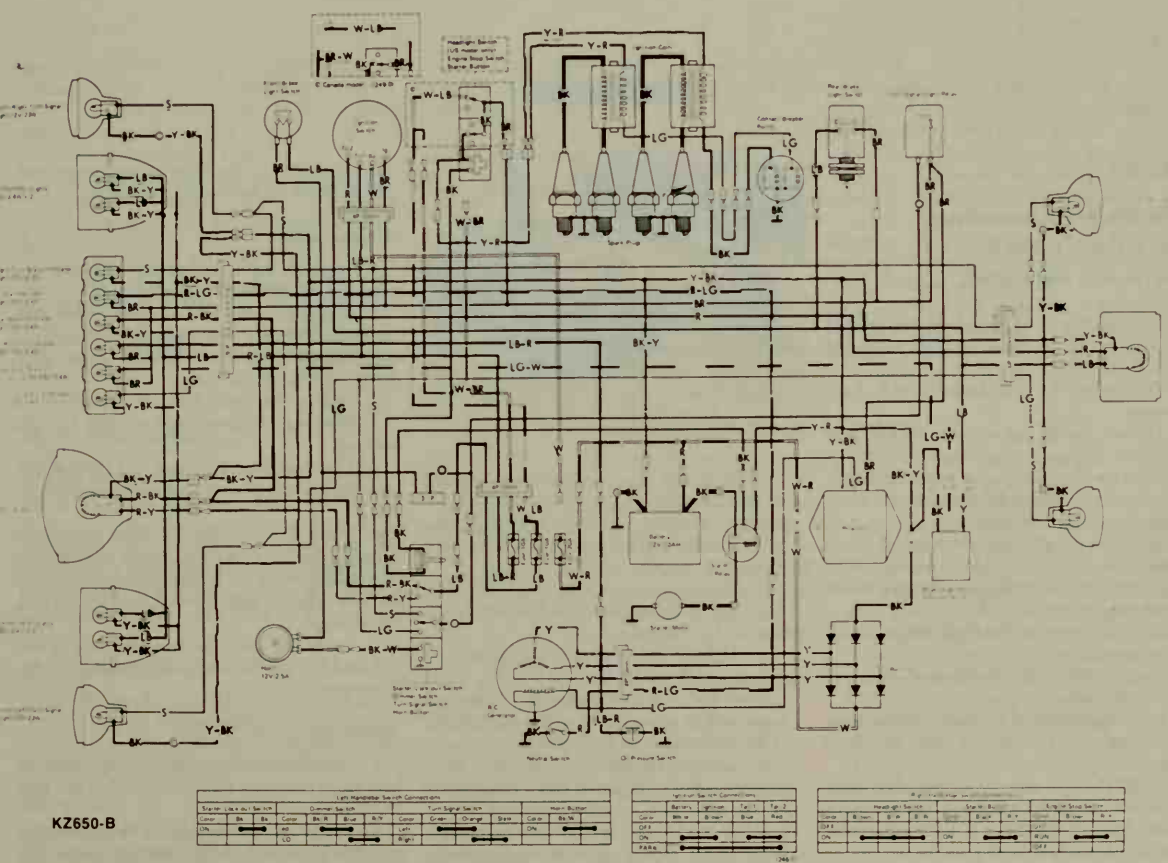
6. To check the switch itself, disconnect the orange/green, green, and grey hazard switch leads under the gas tank. When the switch is "off" there should be no continuity between the leads. When the switch is "on," there should be continuity between all three of the leads. If this is not the case, replace the switch.

7. Remove the right side cover and disconnect the hazard relay leads. Check the resistance across the relay terminals. It should be 60 ohms. If the measure resistance is not in this range, replace the relay.

Horn

1. If the horn fails to sound, check that the battery is not too low.

2. With an ohmmeter set on the R x 1 range, disconnect the horn wires and check for continuity across the horn terminals. Resistance should be zero. If any resistance is noted, replace the horn.



3. If horn resistance is satisfactory, connect a voltmeter across the horn wires, and with the ignition on, push the horn button. When this is done, the meter should read battery voltage. If it does, replace the horn. If not, check the fuse, ignition switch, and wiring connections.

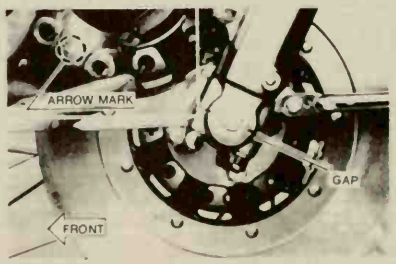
CHASSIS

WHEELS

Front Wheel Assembly

SINGLE DISC BRAKE

Removal and Installation



1. Support the front wheel off the ground by placing a jack or other suitable means of support beneath the engine.
2. Disconnect the speedometer cable from the wheel.
3. Loosen, but do not remove, the four axle clamp nuts. Loosen the axle nuts.
4. Remove the axle clamp nuts, lockwashers, and clamps. Drop the front wheel down and remove it from the motorcycle.
5. Insert a suitably sized wedge of wood between the disc brake pads to prevent their being moved out of position in the event that the brake lever is operated.

NOTE: *Do not allow the brake disc to touch the ground.*

6. Installation is the reverse of removal. Note the following points:

a. Place the wheel in position and gradually lower the motorcycle until the forks engage the axle.

b. Fit the axle caps noting that they *must* be fitted so that the arrow on the caps points towards the *front* of the motorcycle. Install the axle cap nuts loosely.

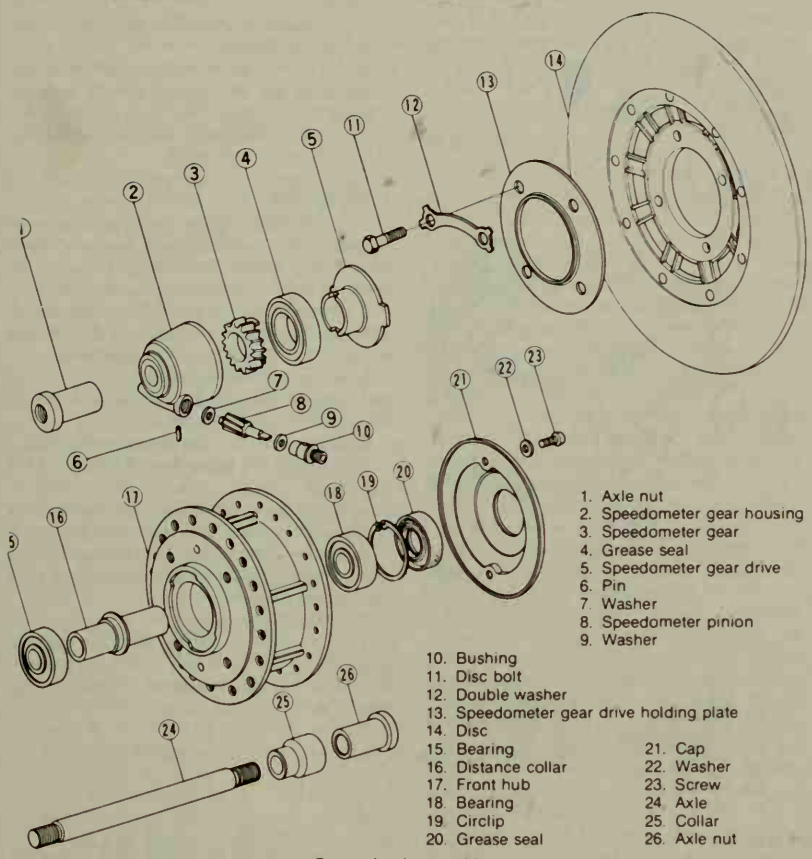
Correct axle cap installation

c. Turn the speedometer gear housing so that it points towards the two o'clock position. Be sure that the small projection on the housing does not catch on the fork tube.

d. Tighten the axle nuts to 51–65 ft lbs. Turn the speedometer gear housing clockwise until it stops.

e. Tighten the front axle cap nuts *first*, tightening them to 11.5–16.0 ft lbs. Then tighten the rear axle cap nuts. Note that there will be a gap between the cap and the slider at the rear of the slider.

f. Connect the speedometer cable, turning the wheel slowly to fully engage the cable end.



CAUTION: *Do not operate the motorcycle until front brake operation has been checked. Pump the brake several times and then check operation before riding.*

Disassembly

1. Remove the disc-side axle nut and remove the speedometer gear housing.
2. Straighten the tabs on the brake disc washers. Remove the disc bolts, washers, speedometer gear drive holding plate, gear drive, and the brake disc.
3. Pull out the axle. Remove the collar.
4. Remove the screws and washers and the hub cap.
5. Use a small screwdriver or a hooked tool and pry out the grease seal. Remove the circlip.
6. Insert a rod into the hub from the speedometer gear side and tap evenly around the circumference of the right-side bearing to remove it from the hub. The bearing spacer will come out as well.
7. Insert the rod into the other side of the hub and tap out the remaining bearing in the same manner.

Assembly

1. Pack the bearings with a good grade of bearing grease. Put a small handful in the hub as well.
2. Use wheel bearing driver or similar tool to drive home one of the bearings. Drive the

bearing in until it is fully seated. Install the spacer and the remaining bearing.

3. Use new grease seals. Seals should be pressed in until the face of the seal is flush with the surface of the hub.

4. Fit the speedometer gear drive into the hub notches. The gear drive holding plate must be installed with the plain side facing the hub.

5. Tighten the disc mounting bolts to 25–33 ft lbs. Bend up the washer tabs against the bolt flats.

6. Clean off any grease or foreign matter which may have gotten on the disc with a non-oily solvent.

DUAL DISC BRAKE

Removal and Installation

Removal and installation of the front wheel is accomplished in the same manner as for the single disc outlined above except that the calipers must be removed from the fork sliders first. After reinstalling the wheel, tighten the caliper mounting bolts to 25–33 ft lbs.

Disassembly

Hub disassembly for the cast-wheel models is the same as for the single disc described above. The only difference is that two brake discs must be removed.

Assembly

Assembly of the hub is the same as outlined for the single disc, above. If wheel bearings of the sealed type are used, install them with the seals facing inwards to keep out dirt and foreign matter.

Rear Wheel Assembly

DRUM BRAKE

Removal and Installation

1. Park the motorcycle on the center-stand.

2. Disconnect the rear brake light switch spring from the brake pedal.

3. Unscrew and remove the adjusting nut from the brake rod. Press down on the brake pedal and disengage the rod from the brake hub lever. Remove the rod spring.

4. Remove the safety clip from the rear torque link bolt on the hub. Remove the nut, lockwasher, and bolt.

5. Remove the cotter pin and loosen the axle nut.

6. Remove the chain guard.

7. Loosen the chain adjuster bolt locknuts on each side and back out the adjusting bolts. Push the wheel forward as far as possible.

8. Remove the bolts and take out the chain adjuster stoppers.

9. Disengage the chain from the rear sprocket. Pull off the wheel.

10. Installation is basically the reverse of removal. Note the following points:

a. If the wheel has been disassembled, check that the coupling collar, coupling sleeve, rubber damper, and brake plate are in place.

b. Insert the rear axle through the left-side chain adjuster (notch mark facing outwards), coupling collar, coupling, coupling sleeve, rear hub, brake plate, spacer, right-side chain adjuster (notch mark facing outwards).

c. Put the rear wheel into place. Install the chain adjuster stoppers. Tighten the bolts.

d. Engage the drive chain onto the rear sprocket.

e. Fit the chain guard.

f. Install the axle nut, but do not tighten it yet.

g. Install the torque link components, tightening the nut loosely.

h. Adjust the chain.

i. Fit the brake rod through the lever (having first installed the spring). Fit the brake adjusting nut.

j. Tighten the axle nut to 72–101 ft lbs. Tighten the brake torque link nut to 19–25 ft lbs and install the safety clip.

Disassembly

1. Remove the brake assembly from the hub. For brake inspection and service, see below.

2. Remove the coupling assembly.

3. To remove the wheel hub bearings, remove the circlip from the hub. Insert a metal rod into the hub from the brake plate side and remove the left-side bearing by tapping around its circumference. The spacer will come out with the bearing.

4. Remove the remaining bearing by inserting the rod through the other side of the hub and repeating the procedure.

5. To disassemble the wheel coupling, remove the coupling collar from the right side and the coupling sleeve from the opposite side.

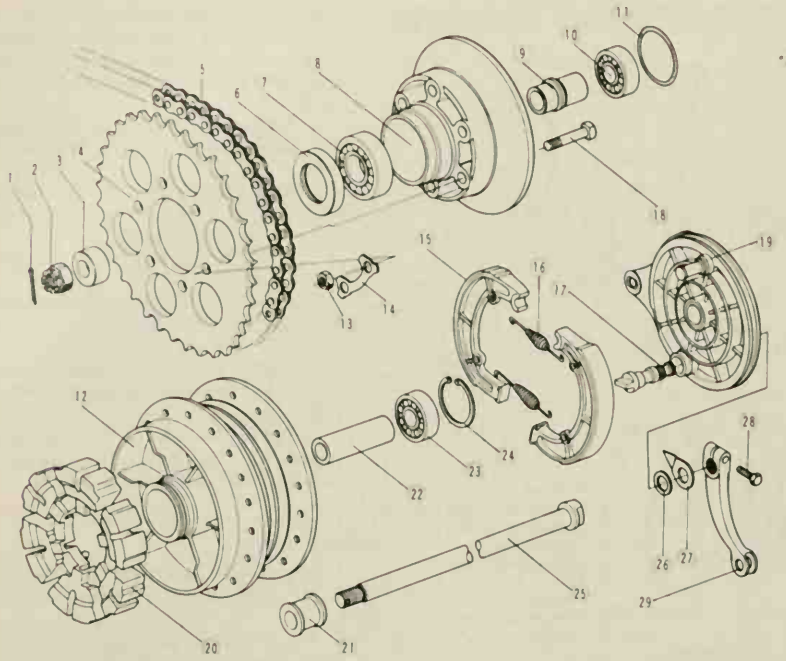
6. Temporarily fit the rubber dampers to the wheel hub and install the coupling to facilitate sprocket removal.

7. Bend down the washers on the sprocket nuts, and remove the nuts. Remove the sprocket. Remove the sprocket bolts.

8. Remove the coupling from the hub. Using a small screwdriver or a hooked tool, pry out the coupling grease seal. A new seal must be used on assembly.

9. Tap out the coupling bearing using a suitable drift, tapping around the circumference of the bearing from the wheel side of the coupling.

Assembly



1. Pack the coupler bearing with a good grade of bearing grease and install it in the coupler using a bearing driver. Drift the bearing straight in until it is fully seated.

2. Use a new coupler grease seal and press the seal into place until the face of the seal is flush with the coupler surface.

3. Fit the sprocket bolts, the sprocket, and the washers and sprocket nuts.

CAUTION: *Be sure to install the sprocket so that the tooth number stamped on the sprocket faces away from the wheel. If this is not done properly, the chain may jump off the sprocket during operation.*

4. Fit the coupler onto the hub to facilitate tightening of the sprocket nuts. Tighten the nuts gradually and in a cross pattern until they are torqued to 26–32 ft lbs. Bend up the tabs on the washers to secure the nuts.

5. Remove the coupler from the hub and fit the coupling sleeve to the right (wheel) side and the coupling collar to the left side.

6. Pack the wheel bearings with a good grade of bearing grease and place a small handful in the hub as well. Drive them into place with a bearing driver or suitable drift. Do not forget to install the bearing spacer. Drive the bearings into the hub until they are fully seated.

7. Check the hub o-ring for condition and replace it if necessary.

DISC BRAKE

Removal and Installation

1. Park the motorcycle on the center stand.

2. Remove the cotter pin and loosen the torque link nut.

3. Remove the chain guard.

4. Loosen the locknuts on the chain adjuster bolts on both sides and back off the adjuster bolts as far as possible.

5. Remove the axle nut cotter pin and loosen the axle nut.

6. Push the wheel forward as far as possible.

7. Remove the bolts and lockwashers and remove the chain adjuster stoppers.

8. Disengage the chain from the rear sprocket.

9. Pull out the rear wheel and caliper.

10. Remove the axle nut and the left-side chain adjuster. Remove the axle and the right-side adjuster.

11. Remove the coupling assembly and rubber damper from the hub and take out the wheel. Reposition the axle in the swing arm to support the caliper assembly.

12. Place a suitable block of wood between the brake pads to prevent their being knocked out of position if the brake pedal was accidentally operated.

NOTE: *Do not allow the brake disc to touch the ground. Always position the wheel with the disc up.*

13. Installation is the reverse of removal. Note the following points:

a. Clean off the old grease and relubricate the o-ring on the rear hub.

b. Remove the wedge from the brake pads and remove the axle if it has been refitted.

c. Slip the wheel into place, installing the rubber damper and coupler assembly. Note that the coupling sleeve must be in place.

d. Fit the caliper into place over the disc and install the axle. The right-side chain adjuster must be installed so that the washer-welded side is towards the left. The hub components should be arranged in the following order: caliper holder, collar, rear hub, coupling sleeve, coupling, coupling collar, left-side chain adjuster (with the alignment mark facing outwards). Fit the axle nut.

e. Install the wheel onto the swing arm.

f. Install the chain adjuster stoppers. Tighten the bolts.

g. Engage the drive chain onto the sprocket.

h. Install the chain guard. Be sure that the front inside part of the chain guard is inserted between the two holding plates.

i. The remainder of the procedure is the reverse of removal.

CAUTION: *Check brake operation before operating the motorcycle. Pump the brake pedal several times and check efficiency before riding. The brake may not work upon first operating the pedal.*

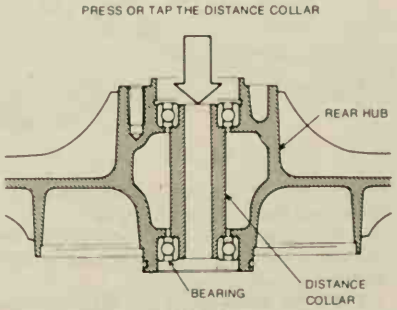
Disassembly

1. To disassemble the coupling, temporarily install the coupling onto the hub. Bend down the washer tabs and remove the sprocket nuts and remove the sprocket.

2. Remove the coupling from the wheel. Remove the coupling collar from the left and the coupling sleeve from the right side.

3. Using a small screwdriver or a hooked tool, pry out the coupling grease seal. A new seal must be used on assembly.

4. Tap out the bearing from the wheel side.



5. Remove the collar from the disc side of the wheel.

6. Bend down the washer tabs and remove the brake disc bolts to remove the disc.

7. Pry out the grease seal using a small screwdriver or a hooked tool. A new seal must be used on assembly.

8. Remove the circlip.

9. Tap or press on the distance collar to remove one of the wheel bearings. Remove the collar and the remaining bearing by tapping it out.

Removing the wheel bearings

should be smooth, noiseless, and free of binding or unevenness. If any of the above conditions exist, both bearings should be replaced.

4. Place each bearing on a flat surface and hold the inner race firmly in place. Attempt to move the outer race up and down. If any play is evident, the bearings should be replaced.

Assembly

1. Pack the coupling bearing with a good grade of bearing grease and install it using a bearing driver or a suitable substitute.

2. Press in a new coupling grease seal until the face of the seal is level with the coupling surface. Grease the seal lip.

3. Install the rear sprocket with the numbered side facing outwards. Tighten the sprocket nuts to 26-32 ft lbs. Bend up the tabs on the washers.

CAUTION: *Be sure that the sprocket is installed with the numbered side facing outwards.*

4. Install the bearings in the hub by driving them in with a bearing driver or suitable substitute. Drive the bearings in until they are fully seated. Do not forget the distance collar. If the bearings are the sealed type, install them with the sealed side facing inward.

5. Install the circlip.
6. Install the grease seal, pressing it in as far as possible.

FRONT DISC BRAKE

Before attempting work on the hydraulic disc brake system, note the following points:

a. Never use brake fluid from an old or an unsealed container. Brake fluid is hydroscopic—it absorbs moisture—and therefore quickly becomes useless unless kept in a sealed environment.

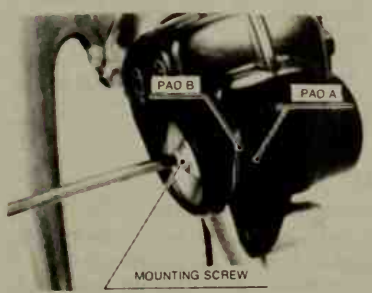
b. Never reuse brake fluid which has been flushed from the system.

c. The system uses DOT 3 brake fluid. This standard is marked on the can. Do not use any other type. Do not mix types or brands of brake fluid, as they may not be compatible.

d. When handling brake fluid, cover all painted parts (such as the gas tank) which may be accidentally damaged by spillage. Brake fluid will remove paint in short order.

e. Keep brake fluid away from the pads and disc surfaces. If there is contact, clean them off immediately with a non-oily solvent. If pads cannot be cleaned, replace them.

f. With the exception of the pads and disc, all internal caliper and master cylinder parts should be cleaned in new brake fluid *only*. Do not attempt to clean these parts in solvents of any type.



g. Any time any of the brake line connections have been loosened or disconnected, the system must be bled to remove air. Refer to the section below.

KZ650-B

PAD REPLACEMENT

1. Pads should be replaced when worn to the limit line.
2. Remove the front wheel.
3. Remove the mounting screw for the inner pad (Pad B) and remove the pad, lockwasher, and metal plate.
4. Move the caliper body as far as possible to the right and remove Pad A. If removal is not possible, apply the brake lever several times until the pad comes out.
5. Install Pad A first. Attach a hose to the bleed valve and run one end into a container. Loosen the bleed valve, and push the piston in by hand as far as possible. Then close the valve. Install the pad. Wipe up any spilled brake fluid immediately.

NOTE: *If a shim is fitted to the pad, install the pad so that the shim is towards the front of the bike.*

Removing the mounting screw

6. Install Pad B, aligning the tongue on the pad with the groove in the caliper. Use a non-permanent thread-locking compound on the screw.
7. Bleed the system.

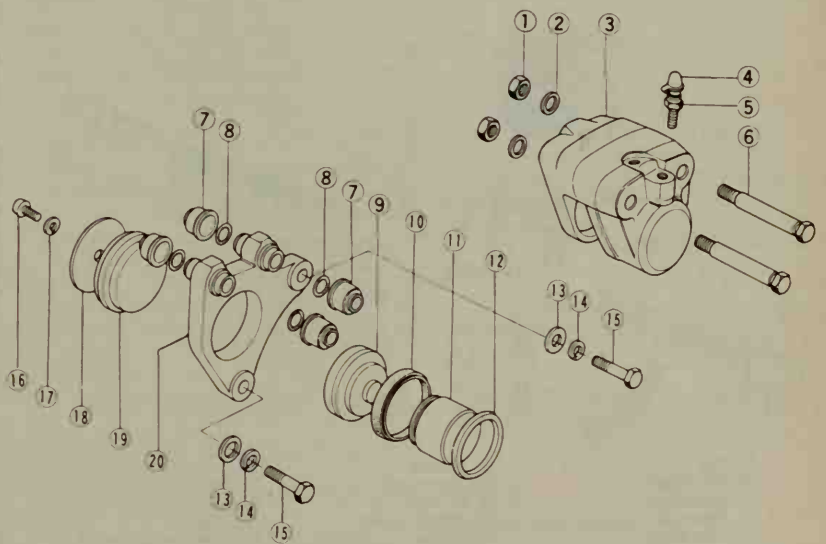
BLEEDING

The purpose of bleeding the brake is to expel any air trapped in the hydraulic system. Since it is compressible, air will cause the brake lever to feel spongy and will decrease braking effectiveness. If the brake lever begins to feel spongy for no apparent reason, it is likely that there is a fault in the hydraulic system. (It would be wise, however, to determine and remedy the fault rather than merely bleed the brake and hope the problem will disappear).

The brake hydraulic system must be bled whenever any part of the system has been disconnected or removed for service. When refilling the master cylinder reservoir, use only brake fluid conforming to DOT 3 specifications. Any brand meeting this requirement is acceptable. The brake fluid container of all reputable brands will be plainly marked with the standards the fluid meets or exceeds.

NOTE: *If you have a double disc setup, bleed the side furthest from the master cylinder first, then bleed the other side. Pulling and tapping on the lines will help expel any air bubbles trapped in the system. If you find that you can't get the system bled properly and the master cylinder has been dry for awhile, the seals inside the cylinder may have become dried and cracked. In this case rebuild the master cylinder.*

1. Top up the reservoir with brake fluid and replace the cap to keep dirt and moisture out and the fluid in. Cover the gas tank with a thick cloth to avoid damage due to spilled brake fluid.
2. Attach one end of a small diameter rubber hose to the bleed valve on the caliper, and place the other end in a jar which contains several inches of clean, new brake fluid. Be sure that the end of the hose is submerged in this fluid. Arrange the hose so that it loops upward after leaving the bleed valve, and see that it has no kinks or sharp bends.
3. Pump the brake lever rapidly several times until some resistance is felt and, holding the lever against the resistance, open the bleed valve about one-half turn. When the lever bottoms, close the valve (do not overtighten) and then release the lever.
4. Repeat this operation until no more air is released out of the hose and the brake lever is firm in operation. Check the fluid level in the reservoir often to make sure that it doesn't go dry and draw more air into the system. Do not reuse fluid that has been pumped out of the system. Do not use fluid that has been stored for more than a few weeks after the seal on its container has been opened, as brake fluid will absorb moisture from the air and may corrode the master cylinder and caliper.
5. Refill the reservoir to the level mark when through (but do not overfill). Avoid overtightening the cap or fluid will weep around the cap edge.



CALIPER

Removal

1. If the caliper is to be disassembled, loosen the caliper holder shaft nuts at this time.
2. Disconnect the brake pipe from the caliper. Plug the end with the bleed valve cap to prevent fluid leakage.
3. Remove the caliper mounting bolts and take off the caliper.

Disassembly

1. Remove the screw for Pad B and remove the pad. Remove the lockwasher and metal plate.
2. Remove the caliper holder shaft nuts and remove the caliper shafts and spacers. This should be done carefully to avoid damage to the dust covers and o-rings.

Caliper assembly

3. Remove the caliper holder and take out Pad A.
4. Remove the piston dust seal.
5. Cover the caliper opening with a clean, heavy cloth. Apply compressed air to the brake line fitting to force out the caliper piston. If a compressed air source is not available, the piston can be removed by reconnecting the brake line to the caliper and applying the brake.
6. Using a small, hooked tool, remove the fluid seal, taking care not to damage the bore surface.

Inspection

1. Check piston and caliper bore diameters against the following:

Bore ID	
Standard	42.850–42.900 mm/ 1.687–1.689 in.
Serviceable limit	42.92 mm/1.69 in.
Piston OD	
Standard	42.788–42.820 mm/ 1.685–1.686 in.
Serviceable limit	42.75 mm/1.68 in.

2. Clean all parts in clean brake fluid. The use of new seals is recommended.
3. The fluid seal should be replaced every other time that the pads are replaced, or if there is fluid leakage around the pad, a problem with brake overheating, there is a difference in the wear of the two pads, or if the seal is stuck to the piston. If the fluid seal is replaced, replace the dust seal as well.
4. Inspect the dust covers and o-rings and replace them if they are cracked or otherwise damaged.

Assembly

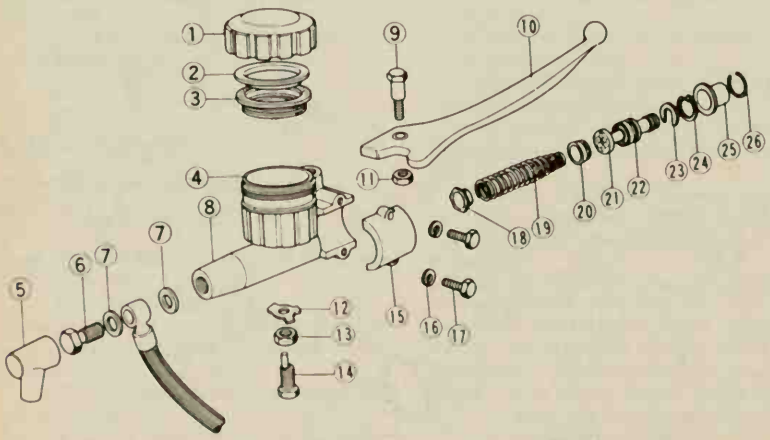
1. Lubricate all parts with new brake fluid during the assembly process.
2. Lubricate the cliper shafts with PBC (high-temperature, water-resistant) grease.
3. Assembly is the reverse of disassembly. Install the spacers with the protruding side facing in. Tighten caliper holder shaft nuts after mounting the caliper on the slider.

Installation

1. Tighten the mounting bolts to 25–33 ft lbs.
2. Tighten the caliper shaft nuts to 17.5–20.0 ft lbs.
3. Tighten the brake line fitting to 12–13 ft lbs.
4. Bleed the system after installation of pads and wheel.

MASTER CYLINDER

Removal



1. Read the cautionary notes at the beginning of the "Front Disc Brake" Section.
2. Remove the right-side rear view mirror.
3. Open the bleeder valve on the caliper, and pump all of the brake fluid out of the system.
4. Remove the banjo bolt which secures the brake line to the master cylinder, then remove the rest of the brake line as desired.
5. Remove the clamp bolts which secure the master cylinder, and remove the cylinder.

Disassembly

1. Remove the reservoir cap, diaphragm plate, and diaphragm, then empty out any residual brake fluid.
2. Remove the brake lever, then use either the special tool (Part No. 56019-111) or a suitable substitute to remove the dust cover stopper. Remove the dust cover.
3. Remove the retaining ring using retaining ring pliers, then remove the stopper, piston, primary cup, spring, and check valve from the master cylinder body.

CAUTION: *Do not attempt to remove the secondary cup from the piston as this will damage the cup.*

4. Any remaining components such as the pressure switch, the 3-way fitting, the brake lines and pipe may be removed at this time.

Master cylinder assembly

Inspection

1. Clean all parts in clean brake fluid, then blow them dry. Use compressed air to blow out all passages. A clogged relief port will result in the pads dragging on the disc.
2. Inspect the master cylinder bore and piston for signs of wear, rust, pitting, or damage, and replace as necessary. The master cylinder and piston must also be replaced if worn past their serviceable limit.
3. Inspect the primary and secondary cups for signs of wear, damage, rotting, or swelling, and replace them as necessary. Leaking at the brake lever is an indication of bad cups. The piston must also be replaced if the secondary cup is damaged, however, it's best to replace the cups as a set.
4. Inspect the spring for signs of wear or damage, and replace it as necessary.
5. Replace the rubber dust cover if it is damaged or aged.
6. Inspect the fittings, hoses, and pipes for signs of wear, cracking, rust, or other damage and replace them as necessary.
7. The necessary specifications for determining the serviceability of the master cylinder components are as follows:

Cylinder inside diameter	
Standard	14.000–14.043 mm/ 0.5512–0.5529 in.
Serviceable limit	14.080 mm/0.5543 in.
Piston outside diameter	
Standard	13.957–13.984 mm/ 0.5495–0.5506 in.
Serviceable limit	13.900 mm/0.5472 in.
Primary, secondary cup diameter	
Standard	14.650–15.150 mm/ 0.5768–0.5965 in.
Serviceable limit	14.500 mm/0.5709 in.
Spring free-length	
Standard	51.0 mm/2.008 in.
Serviceable limit	48.0 mm/1.890 in.

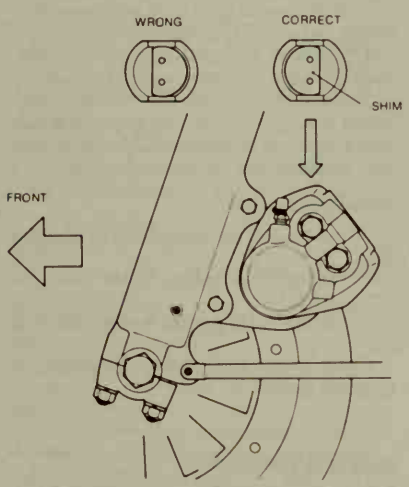
Assembly and Installation

1. Assembly is basically in the reverse order of disassembly. Make sure that all internal parts are perfectly clean, and liberally coat them all with clean brake fluid before installing.
2. Make sure that the primary cup and the check valve are not installed backwards, and make sure that they aren't distorted or turned sideways after insertion.
3. Use either the factory tool (Part No. 56019-110) or a suitable substitute to install a new retaining ring in its groove in the cylinder wall. The same tool can be used to install the boot and boot stopper.
4. Install the master cylinder so that the small projection is toward the throttle grip. Secure the lower camp bolts first, then secure the upper bolts. The bolts should be torqued to 55–75 in. lbs (0.63–0.88 kg/m).
5. Fill the master cylinder with brake fluid and bleed the system as described in the "Bleeding" section. Do not overtighten the master cylinder cap.

DISC

Removal and Installation

1. To remove the disc, bend down the lockwashers and remove the mounting bolts.
2. To install, tighten the bolts to 25–33 ft lbs.



Inspection

1. Standard disc thickness is 6.9–7.1 mm (0.27–0.28 in.). Serviceable limit is 6 mm (0.24 in.).
2. Max. allowable run-out is 0.3 mm (0.012 in.).

KZ650-C/D

PAD REPLACEMENT

1. Pads should be replaced when they are worn to the limit lines.
2. Remove the caliper mounting bolts and take the caliper(s) off the fork sliders.
3. Remove the mounting screw for the inner pad (Pad B) and remove the pad along with the lockwasher and metal plate.
4. Slide the caliper holder to the piston side and remove Pad A.
5. Remove the cap from the caliper bleed valve and fit one end of a plastic line to it, running the other end into a suitable container.
6. Loosen the bleed valve and push the piston in by hand as far as possible. Close the valve.
7. Install Pad A. Fit the pad so that the shim is towards the front of the motorcycle.
8. Install Pad B, aligning the tongue on the pad with the groove in the caliper. Use a non-permanent thread-locking compound on the pad mounting screw.

Install the pad so that the shim is towards the front of the motorcycle

9. Install the calipers onto the fork sliders, tightening the mounting bolts to 25–33 ft lbs.
10. Check the fluid level in the master cylinder, and bleed the system.

CAUTION: *Operate the brake lever several times to position the brake pads. Check brake operation before attempting to ride the motorcycle.*

BLEEDING

Refer to the "Bleeding" section for the KZ650-B, above. The procedure is the same.

CALIPER

Removal

1. If the calipers are to be disassembled, first loosen the caliper holder shaft nuts.
2. Disconnect the brake line at the caliper and arrange the line upwards to avoid fluid loss.
3. Remove the caliper mounting bolts and take off the calipers.

Disassembly

1. Remove the screw for Pad B and remove the pad. Remove the lockwasher and metal plate.
2. Remove the caliper holder shaft nuts and remove the caliper shafts and spacers. This should be done carefully to avoid damage to the dust covers and o-rings.
3. Remove the caliper holder and take out Pad A.
4. Remove the piston dust seal.
5. Cover the caliper opening with a clean, heavy cloth. Apply compressed air to the brake line fitting to force out the caliper piston. If a compressed air source is not available, the piston can be removed by reconnecting the brake line to the caliper and applying the brake.
6. Using a small, hooked tool, remove the fluid seal, taking care not to damage the bore surface.

Inspection

1. Check piston and caliper bore diameters against the following:

Bore ID	
Standard	38.180–38.230 mm/ 1.503–1.505 in.
Serviceable limit	38.25 mm/1.506 in.
Piston OD	
Standard	38.116–38.148 mm/ 1.501–1.502 in.
Serviceable limit	38.08 mm/1.499 in.

2. Clean all parts in new brake fluid. The use of new seals is recommended.
3. The fluid seal should be replaced every other time that the pads are replaced, or if there is fluid leakage around the pad, a problem with brake overheating, there is a difference in the wear of the two pads, or if the seal is stuck to the piston. If the fluid seal is replaced, replace the dust seal as well.
4. Inspect the dust covers and o-rings and replace them if they are cracked or otherwise damaged.

Assembly

1. Lubricate all parts with new brake fluid during the assembly process.
2. Lubricate the caliper shafts with PBC (high-temperature, water-resistant) grease.
3. Assembly is the reverse of disassembly. Install the spacers with the protruding side facing in. Tighten caliper holder shaft nuts after mounting the caliper on the slider.

Installation

1. Tighten the mounting bolts to 25–33 ft lbs.
2. Tighten the caliper shaft nuts to 17.5–20.0 ft lbs.
3. Tighten the brake line fitting to 12–13 ft lbs.
4. Bleed the system after installation of pads and wheel.

MASTER CYLINDER

Service procedures for the master cylinder on the KZ650-C/D are the same as for that outlined for the KZ650-B. Refer to that section, above.

Note that master cylinder specifications are different, however. They are as follows:

Bore inside diameter	
Standard	15.870–15.913 mm/ 0.6248–0.6265 in.
Serviceable limit	15.95 mm/0.6280 in.
Piston outside diameter	
Standard	15.827–15.854 mm/ 0.6231–0.6242 in.
Serviceable limit	15.77 mm/0.6209 in.
Primary, secondary cup diameter	
Standard	16.45–16.95 mm/ 0.6476–0.6673 in.
Serviceable limit	16.30 mm/0.6417 in.
Spring free-length	
Standard	39.2–43.2 mm/ 1.54–1.70 in.
Serviceable limit	37.2 mm/1.46 in.

DISC

Removal and Installation

1. To remove the dise(s), remove the wheel, bend down the washer locktabs and remove the mounting bolts.
2. To install, tighten the disc bolts to 25–33 ft lbs. Bend up the locktabs across the bolt flats.

Inspection

The disc can be inspected without removing it from the machine.

1. Check disc run-out with a dial gauge. Standard run-out is less than 0.15 mm (0.006 in.). Maximum allowable run-out is 0.3 mm (0.012 in.). If run-out exceeds this figure, replace the disc.
2. Standard disc thickness, measured with a micrometer, is 4.9–5.1 mm (0.19–0.20 in.). Replace the disc if the measured thickness is less than 4 mm (0.16 in.).

REAR BRAKES

Rear Drum

REMOVAL

1. Remove the rear wheel. Take out the brake panel.
2. Using rags to avoid getting grease or oil on the brake linings, remove the linings by folding them in towards the center of the brake panel. Disengage the springs and remove the linings.
3. Mark the position of the cam lever relative to the cam so that it can be reinstalled in the same position. Unbolt and remove the lever. Remove the lining wear indicator, dust seal, and the cam.

INSPECTION

1. Measure the inside diameter of the brake drum. Standard diameter is 180.0–180.2 mm (7087–7.094 in.). Replace the drum if the measured diameter is greater than 180.75 mm (7.116 in.).
2. Measure the thickness of the brake linings at their thinnest point. Thickness of new linings is 4.86–5.80 mm (0.191–0.228 in.). Linings should be replaced as a set if either measures less than 2.5 mm (0.098 in.) at the thinest point.
3. Check the linings for uneven wear and sand down any high spots. Clean the linings thoroughly afterwards.
4. Remove any foreign matter imbedded in the linings with a wire brush.
5. Clean the linings with a non-oily solvent to remove any oil or grease. If the linings cannot be cleaned in this manner, replace them.
6. Check the free-length of each of the brake return springs. Standard free-length is 66.0–67.0 mm (2.60–2.64 in.). Replace the springs as a set if either measures more than 69.0 mm (2.72 in.).
7. Measure the diameter of the brake cam where it rides on the brake panel, and measure the inside diameter of the cam hole as well. Replace the cam if the diameter is less than 16.83 mm (0.663 in.). Replace the brake panel if the hole diameter is more than 17.22 mm (0.678 in.).
8. Wipe the old grease from the brake cam and lubricate it thoroughly with a good grade of chassis grease. Fill the cam groove with grease. Grease the brake shoe anchor pin as well. Be sure not to get any grease on the linings.

INSTALLATION

1. Install the camshaft.
2. Fit the return springs onto the shoes and bend the linings over the anchor and cam in the reverse of the removal process.
3. Fit the dust seal and install the wear indicator onto the cam so that it points to the extreme right of the letters "USABLE RANGE."
4. Install the cam lever in the position marked on removal, and tighten the bolt.

Rear Disc (1976–1979)

NOTE: *Before attempting any work on the rear disc brake, read the cautions provided in the beginning of the section "Front Disc Brake," above.*

PAD REPLACEMENT

1. Remove the rear wheel.
2. Unbolt and remove the caliper.
3. Remove the mounting screw for the inner pad (Pad B) and remove the pad along with the lockwasher and metal plate.
4. Slide the caliper holder to the piston side and remove Pad A.

If pad A is difficult to remove, apply the brake pedal to force it out.

5. To install the pads, remove the cap on the bleed valve, and fit a plastic hose, running the other end of the hose into a suitable container.
6. Open the bleed valve slightly and push in the piston as far as it will go by hand. Close the valve.
7. Install Pad A in the caliper holder, aligning the groove of the pad with the ridge in the caliper holder.
8. Install Pad B, aligning the tongue on the pad with the groove in the caliper. Use a non-permanent thread-locking compound on the pad mounting screw.
9. Bleed the system.

Align the tongue on the pad with the groove on the caliper

CAUTION: *Apply the brake several times and check brake efficiency before operating the motorcycle. The pedal may not function the first time it is operated.*

CALIPER

Removal

1. Remove the rear wheel.
2. If the caliper is to be disassembled, loosen the caliper holder shaft nuts at this point.
3. Disconnect the brake line at the caliper and arrange the line at a high spot to prevent fluid loss.

4. Remove the torque link nut at the caliper and remove the caliper from the motorcycle.

Disassembly

Disassemble the caliper in the same manner as described for the KZ650-C front brake calipers, above.

Inspection

1. Measure the piston diameter. Standard diameter is 42.788–42.820 mm (1.6846–1.6858 in.). Replace the piston if the measured diameter is less than 42.75 mm (1.683 in.).
2. Measure the caliper bore diameter. Standard bore diameter is 42.850–42.900 mm (1.6870–1.6890 in.). Replace the caliper body if the bore exceeds 42.92 mm (1.690 in.).

Assembly

1. Lubricate all parts with new brake fluid during the assembly process.
2. Lubricate the caliper shafts with PBC (high-temperature, water-resistant) grease.
3. Assembly is the reverse of disassembly. Install the spacers with the protruding side facing in. Tighten caliper holder shaft nuts after mounting the caliper on the slider.

Installation

1. Tighten the mounting bolts to 21–22 ft lbs.
2. Tighten the caliper shaft nuts to 17.5–20.0 ft lbs.
3. Tighten the brake line fitting to 12–13 ft lbs.
4. Bleed the system after installation of pads and wheel.

MASTER CYLINDER

Removal

1. Remove the right side cover.
2. Disconnect the brake line fitting on the master cylinder. Watch for split brake fluid. Wipe up any spills immediately.
3. Remove the master cylinder mounting bolts and take off the master cylinder.

Disassembly

1. Remove the pushrod dust cover.
2. Remove the master cylinder cap and pour off the brake fluid.
3. Use a thin screwdriver to remove the retainer and take out the piston stopper and piston. Do not remove the secondary cup from the piston as it will be damaged.
4. Remove the return spring and primary cup by applying compressed air to the brake fluid outlet hole.

Inspection

1. Clean all parts in clean brake fluid, then blow them dry. Use compressed air to blow

out all passages. A clogged relief port will result in the pads dragging on the disc.

2. Inspect the master cylinder bore and piston for signs of wear, rust, pitting, or damage, and replace as necessary. The master cylinder and piston must also be replaced if worn past their serviceable limit.

3. Inspect the primary and secondary cups for signs of wear, damage, rotting, or swelling, and replace them as necessary. Leaking at the brake lever is an indication of bad cups. The piston must also be replaced if the secondary cup is damaged, however, it's best to replace the cups as a set.

4. Inspect the spring for signs of wear or damage, and replace it as necessary.

5. Replace the rubber dust cover if it is damaged or aged.

6. Inspect the fittings, hoses, and pipes for signs of wear, cracking, rust, or other damage and replace them as necessary.

7. The necessary specifications for determining the serviceability of the master cylinder components are as follows:

Cylinder bore diameter	
Standard	14.000–14.043 mm/ 0.5512–0.5529 in.
Serviceable limit	14.08 mm/0.5543 in.
Piston outside diameter	
Standard	13.957–13.984 mm/ 0.5495–0.5506 in.
Serviceable limit	13.90 mm/0.5472 in.
Primary, secondary cup diameter	
Standard	14.65–15.15 mm/ 0.577–0.596 in.
Serviceable limit	14.50 mm/0.571 in.
Spring free-length	
Standard	49.1–53.2 mm/ 1.93–2.09 in.
Serviceable limit	46.5 mm/1.83 in.

Assembly

1. Coat all parts with clean, new brake fluid before assembly.

2. Install the return spring. The spring seat side must face outwards.

3. Install the primary cup. Be sure that it is not installed backwards or turned sideways after installation.

4. Install the piston and stopper. Install the retainer in as far as it will go.

5. Install the diaphragm and master cylinder cap. Fit the pushrod dust cover.

6. If the master cylinder plug has been removed, use a new gasket and tighten the plug to 29–36 ft lbs.

Installation

1. Tighten the brake line banjo bolt to 21–22 ft lbs. Be sure that the metal pipe comes to the right side of the stopper on the master cylinder.

2. Bleed the system.

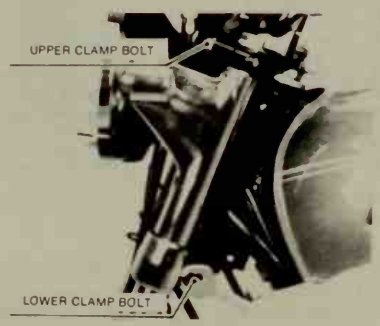
FRONT FORKS (STANDARD)

KZ650-B

REMOVAL

1. Support the front wheel of the motorcycle well off the ground by placing a jack or other sturdy support beneath the engine.



2. Remove the front wheel.

3. Remove the fender.

4. Remove the caliper from the fork slider by removing the two mounting bolts. Support the caliper so that it does not stretch the brake line or bend the pipe.

5. If the fork leg is to be disassembled after removal, loosen the top bolt at this point.

6. Loosen the upper and lower triple clamp bolts.

7. Pull the fork leg down and with a twisting motion to free it from the triple clamps. Repeat the procedure with the other fork leg.

DISASSEMBLY

1. Remove the top bolt. Remove the spring seat and spring. Pour off the oil. It may be necessary to pump the slider to expel all of the oil.

2. Remove the dust seal.

3. Use the special tool to stop the cylinder from turning and remove the allen bolt from the bottom of the fork slider.

If the special tool is not available, it may be possible to remove the allen bolt by temporarily installing the spring and top bolt and then loosening the allen bolt.

4. Remove the fork slider from the fork leg.

5. Remove the cylinder base.

6. Remove the retaining ring on the cylinder and slide the cylinder and piston unit and its spring out of the top of the fork tube.

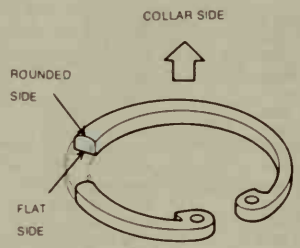
7. Remove the circlip inside the end of the fork tube and pull out the collar, valve, spring, and valve seat.

8. Remove the spring and circlip and pull the piston off the cylinder.

9. Remove the fork slider oil seal retainer using a small screwdriver or a hooked tool. Remove the washer. Pry out the oil seal with a small screwdriver or hooked tool. It will probably be necessary to heat the slider around the area of the seal before removal is possible. New seals must always be used on assembly.

INSPECTION

1. Check the free length of each fork spring. Standard length is 487.5–493.5 mm (19.19–19.43 in.). Replace the springs as a set if either of them measures less than 477.5 mm (18.80 in.).



2. Check the fork tube for damage such as bends or other accident damage. Be sure that the chrome plating is in good condition on the tube, especially in the area on which the oil seals ride. If it is chipped or cracked, replace the tube.

CAUTION: *Do not attempt to straighten crash-damaged or bend fork tubes. Replace them with new ones.*

ASSEMBLY

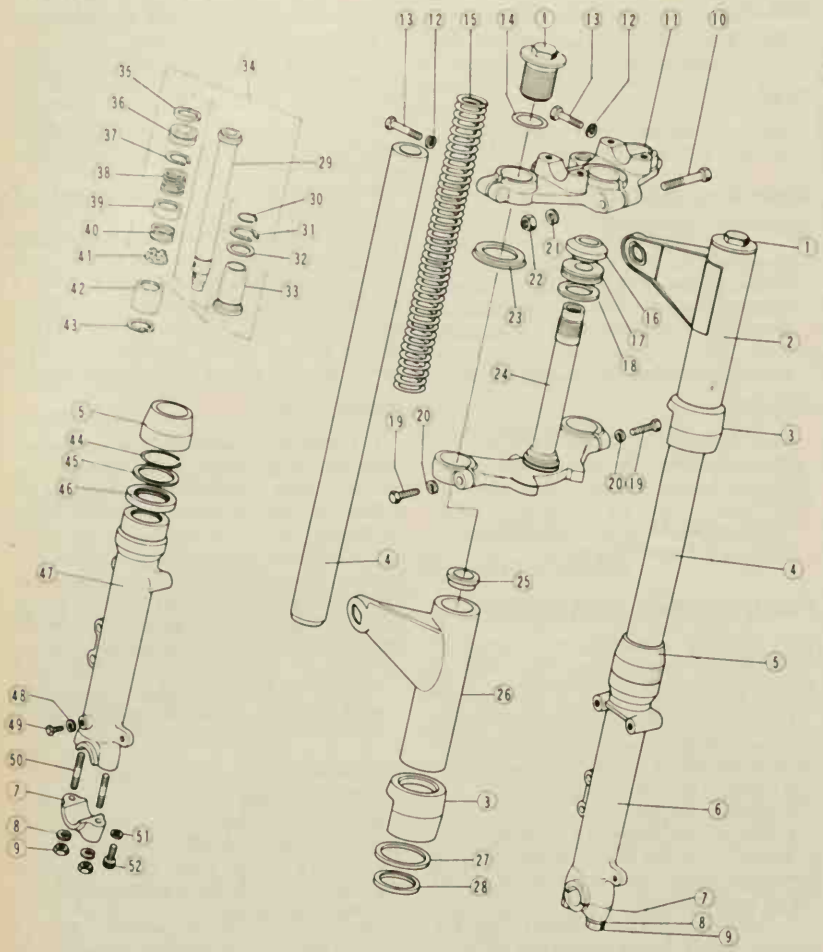
1. With the piston ring guide (Part No. 57001-161) fit the cylinder and piston assembly into the bottom of the fork tube.

2. Install the collar. Install the circlip in the fork tube, noting that the rounded side of the circlip faces the collar.

Install the circlip with the rounded side towards the collar

3. Use a liquid gasket material on both sides of the allen bolt gasket. Use a non-permanent thread-locking compound on the allen bolt itself. Tighten the allen bolt to 14.5–19.0 ft lbs.

4. Use new fork slider oil seals, driving the seals straight in until they are seated properly. Oil the lips of the seal before fitting the slider to the fork tube.



5. Refer to the "Maintenance Data" chart at the end of the "Maintenance section for fork oil capacity.

6. When fitting the fork springs, be sure that they are installed with the close coils towards the top.

7. Tighten the top bolts to 18–22 ft lbs.

INSTALLATION

1. Push the fork leg up into the triple clamps until the upper surface of the top bolt flange is flush with the upper surface of the triple clamp.

Front fork assembly (KZ650-B)

2. Tighten the upper triple clamp bolts to 11.5–16.0 ft lbs. Tighten the lower triple clamp bolts to 25–33 ft lbs.

3. Tighten the top bolt to 18–22 ft lbs., if this has not been done already.

4. Install and tighten the caliper mounting bolts to 25–33 ft lbs.

5. Install the fender and the front wheel.

KZ650-C/D

REMOVAL

1. If the fork leg is to be disassembled after removal, remove the rubber cap from the top of the fork leg and loosen the top bolt.

2. Support the front wheel firmly well off the ground by placing a jack or other suitable support beneath the engine.

3. Remove the front wheel.

4. Remove the fender.

5. Loosen the upper and lower triple clamp bolts. Pull the fork leg down with a twisting motion and remove it from the machine; repeat the procedure with the other fork leg.

DISASSEMBLY

1. Remove the top bolt and take out the spring and spring seat.

2. Pour out and discard the oil. It may be necessary to pump the slider several times to expel all of the oil.

3. Remove the dust seal from the top of the slider.

4. Use the special tool to stop the cylinder from turning and remove the allen bolt from the bottom of the fork slider.

If the special tool is not available, it may be possible to remove the allen bolt by temporarily refitting the spring and top bolt and attempting to loosen the allen bolt.

5. Separate the fork slider from the fork tube.

6. Remove the cylinder base and valve.

7. Slide the piston and cylinder and the spring out of the top of the fork tube.

8. Remove the oil seal retained from the top of the fork slider with a hooked tool. Remove the washer. With a small screwdriver or a hooked tool, remove the slider oil seal. It may be necessary to gently heat the slider in the area around the seal before removing it. New seals must always be used on assembly.

INSPECTION

1. Check the free length of the fork springs. Standard free length is 494.5 mm (19.47 in.). The spring should be replaced if the measured length is less than 485 mm (19.09 in.). Springs should be replaced in sets to ensure equal damping characteristics.

2. Check the fork tubes for bends or other accident damage. Replace the tubes if they are bent.

CAUTION: *Do not attempt to straighten bent tubes.*

3. Check the condition of the chrome plating on the tubes, especially in the area on which the oil seals ride. Scratched or nicked plating may cause oil leaks. If this is the case, replace the tube.

ASSEMBLY

1. Assembly is basically the reverse of disassembly. Note the following points:

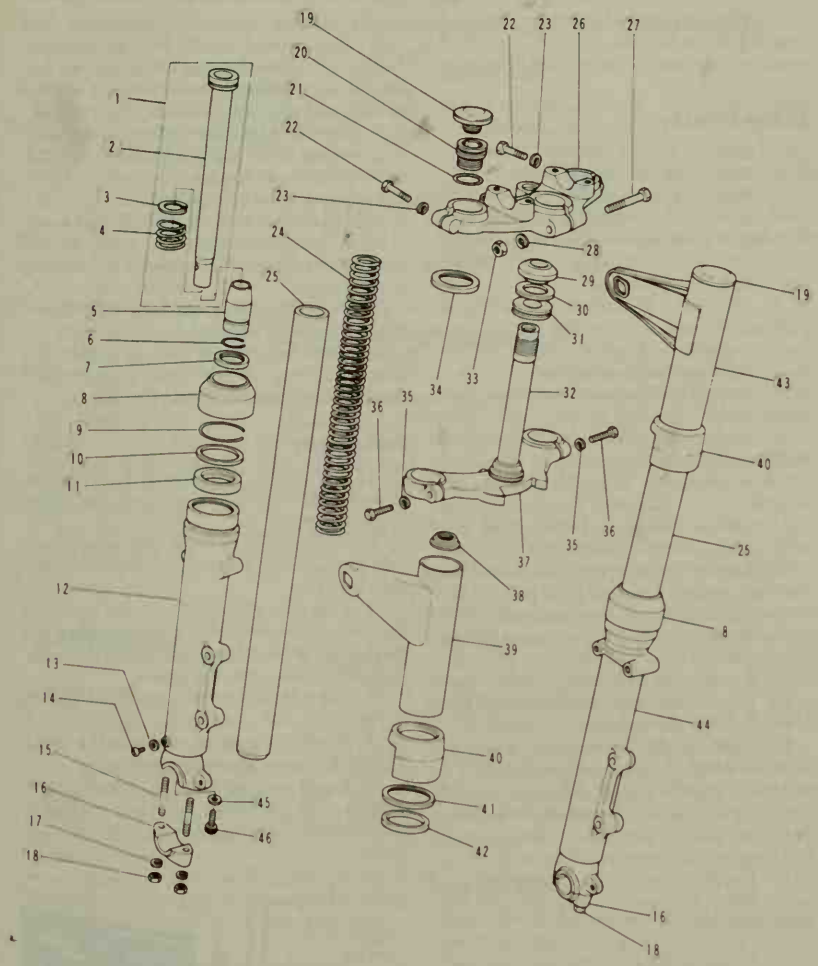
a. Using the special piston ring guide (Part No. 570010161), and turning the fork tube upside down, install the cylinder and piston assembly into the tube from the top end.

b. Apply a liquid gasket compound to both sides of the allen bolt gasket. Use a non-permanent thread-locking compound on the allen bolt threads, tightening it to 14.5–19.0 ft lbs.

c. Use new fork slider oil seals. Oil the lips of the seal before inserting the fork tube into the slider.

d. Refer to the "Maintenance Data" chart at the end of chapter 2 for the correct quantity and grade of oil.

e. After installing the fork leg into the triple clamp, tighten the top bolt to 18–22 ft lbs.



Install the fork tube so that it is about 2 mm below the top surface of the upper triple clamp

INSTALLATION

1. Install the fork leg into the triple clamps until the top edge of the tube is 2 mm below the upper surface of the upper triple clamp.

2. Tighten the upper triple clamp pinch bolts to 11.5–16.0 ft lbs.

3. Tighten the lower triple clamp pinch bolts to 25–33 ft lbs.

4. Tighten the top bolt to 18–22 ft lbs if this has not already been done.
5. Install the fender and the front wheel.

FRONT FORKS (AIR TYPE)

Removal

1. Remove the caliper(s) from the fork leg(s).
2. Remove the front wheel.
3. Remove the fender.
4. Loosen the top plug.
5. Loosen the upper and lower triple clamp bolts. Pull the fork leg down and free of the triple clamps.

Disassembly

1. Remove the air valve and o-ring.
2. Remove the top plug, o-ring, and spring. Pump out the oil.
3. Remove the allen bolt from the bottom of the slider and separate the slider from the fork tube.
4. Remove the cylinder and spring from the top of the fork tube.
5. Remove the seal retainer from the fork slider and pry out the seal. It may be necessary to heat the top of the slider gently to get the seal out. New seals must be used when assembling.

Inspection

1. Measure the free-length of the fork springs and replace both of them if either measures less than the service limit:

KZ650D/F 491 mm/19.3 in.
KZ650H, KZ750E 497 mm/196.6 in.
KZ750H 483 mm/19.0 in.

2. Check the guide bushings for scoring or wear and replace them if damage is present.
3. Check the fork tube for damage such as dents or deep scratches in the chrome, especially in the area on which the slider oil seal moves.

Assembly

Reverse the disassembly procedure. Note the following points:

1. Use liquid gasket compound on both sides of the slider allen bolt gasket. Install and tighten the allen bolt to 16.5 ft lbs. The allen bolt should be secured with a non-permanent thread-locking compound.
2. Use a non-permanent thread-locking compound on the air valves and tighten them to 8.7 ft lbs.
3. Fork oil capacities can be found in "Maintenance." For air pressures, see "Suspension Adjustments," below.

Installation

1. Install the fork leg in the triple clamp in the following manner:

On 650s and the 750E, slide the fork leg in until the upper lip of the fork tube is even with the upper surface of the triple clamp.

On the 750H, the fork legs are installed so that the top surface of the air valve plug is even with the triple clamp surface.

2. Tighten the upper triple clamp pinch bolts to 14.5 ft lbs., and the lower to 27 ft lbs. in that order.

SUSPENSION ADJUSTMENTS

With air forks, it is necessary to coordinate the settings of the front forks and rear shocks.

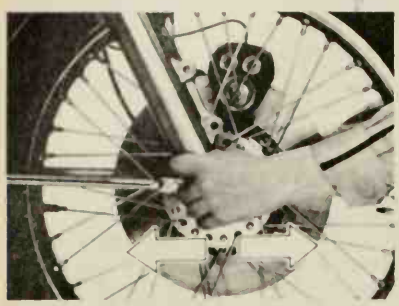
1. Put the motorcycle on the center stand and use a jack beneath the engine to raise the front wheel clear of the ground.
2. Front forks must be cold when checking air pressure.
3. Pressure must be checked with the special gauge. Tire pressure gauges will give misleading readings.
4. Fork air pressure should be as follows:

H-models	7.1–14.0 psi
Other models	8.5–13.0 psi

5. Fork leg pressures must be within 1.4 psi.
6. Inject air with a pump, but do it slowly.

CAUTION: *Pressures exceeding 36 psi may damage the oil seals.*

7. Use only air or nitrogen gas.
8. Rear shocks are adjusted for Spring Force at the bottom and for Damping Force at the top. The settings must conform to the following limits:



Spring Force Setting	Damping Force Setting
1 or 2	1 or 2
2 or 3	2 or 3
3 or 4	3 or 4
4 or 5	3 or 4

STEERING STEM ASSEMBLY

Bearing Adjustment

1. To check bearing adjustment, support the front wheel off the ground. Grasp the bot-

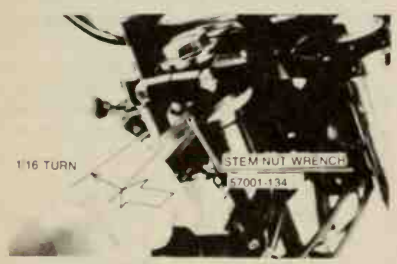
toms of the fork sliders and attempt to move the forks back and forth in line with the motorcycle. Push and pull on the fork sliders. There should be no detectable movement. If there is, the bearings must be adjusted.

Checking for steering stem bearing play

2. Turn the forks slowly from lock-to-lock, again with the front wheel off the ground. Movement should be smooth, silent, and effortless. If any binding or uneven movement is felt, the balls and races are either too tightly adjusted or they are worn. If the steering feels uniformly stiff, the bearings are too tightly adjusted. If any noise is noted, the bearings are damaged or some are missing.

3. With the front wheel off the ground, release the front forks from a few degrees off the centered position. The forks should fall to either side of their own accord. If they will not, the bearings are too tightly adjusted, the steering stem is bent, the races are extremely worn, or some of the bearings are missing.

4. To adjust the bearings, first remove the gas tank. Be sure that the front wheel is firmly supported off the ground.



5. Loosen the lower triple clamp pinch bolts.

6. Loosen the upper triple clamp head pinch bolt, and loosen the steering stem head bolt.

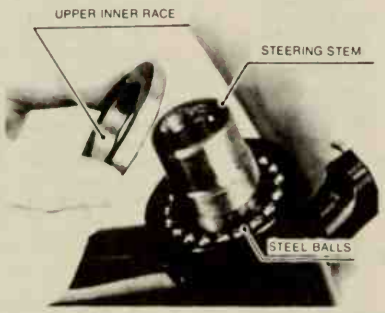
7. Back out the steering stem locknut one or two turns until it turns without resistance using the special wrench.

NOTE: *Do not loosen the locknut more than two turns. To do so risks loosing some of the ball bearings.*

8. Tighten the steering stem locknut to 19.5–24.0 ft lbs. If a torque wrench is not available, turn the locknut until resistance is felt (the locknut becomes hard to turn), then turn it another 1/16 turn (about 20°).

Adjusting the steering stem bearings (1/16 turn after the locknut becomes hard to turn)

9. Check that bearing adjustment conforms to the checks outlined above.



10. Tighten the steering stem head bolt to 29–36 ft lbs. Tighten the pinch bolt to 11.5–16.0 ft lbs.

11. Tighten the lower triple clamp pinch bolts to 25–33 ft lbs.

12. Check bearing adjustment. If the bearings still do not function properly, remove the steering stem and check the parts for wear.

Disassembly

1. Remove the gas tank.
2. Remove the front wheel.
3. Remove the handlebars.
4. Remove the headlight. Disconnect the turn signal leads. Remove the turn signals.
5. Remove the headlight shell. Remove the starter locknut switch.
6. Disconnect the tachometer cable at the instrument. Remove the nuts which secure the instruments and remove them.
7. Remove the front fender.
8. Disconnect the front brake light switch leads.
9. Remove the disc brake line joint from the lower triple clamp.
10. Remove the caliper(s) from the fork slider(s).
11. Loosen the upper triple clamp pinch bolts.
12. Loosen the steering stem head clamp bolt and remove the stem head bolt.
13. Tap lightly on the underside of the upper triple clamp with a plastic mallet and remove it.
14. Remove the fork covers.
15. Loosen the lower triple clamp pinch bolts. Pull out the fork legs.
16. Hold up the lower triple clamp and unscrew the steering stem locknut. When the locknut is completely off the stem, carefully lower the stem assembly out of the head lug. Note that some of the balls in the lower race will drop out as the stem is lowered.
17. Remove the steering stem cap and upper inner race and remove the balls from the upper race.

Removing the upper inner race

18. Inspect the bearings and races as outlined below. If replacement of the frame races is required, remove them by driving them out of the frame lug with a drift and hammer.

19. A special tool is required to remove the lower inner race from the steering stem if replacement is required. The race is pressed on. If the race is removed, replace the grease seal beneath it.

Inspection

1. Wash the ball bearings in a suitable solvent. Ball bearing size is ¼ in.

2. Clean all of the old grease from the bearing race surfaces, steering stem, and frame lug.

3. Inspect the bearing race surfaces. They must be clean and smooth and free of any cracks, scoring, rust, or indentations. Run your finger around each of the bearing races. Note any roughness or ripples on the race surface. If any imperfections are noted, both sets of races and all of the balls must be replaced.

4. Check the balls themselves for rust, pitting, scoring, or flat spots. If the balls are found to be defective in any way, the balls and both sets of races must be replaced.

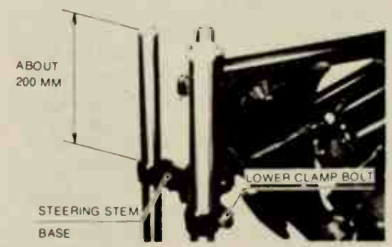
NOTE: *Balls and races must always be replaced in a set because worn races will destroy new balls and worn balls will destroy new races.*

5. Check the grease seal for condition and replace if torn or cracked.

6. Check the steering stem for cracks or a bent condition; this is especially important if the bike has been involved in a spill.

Assembly

1. The frame lug races have been removed, lubricate the new races and drive them into place.



2. Replace the steering stem grease seal with a new one and drive the lower inner race onto the stem.

3. Lubricate the top frame lug race and the lower inner race with a thick coating of a good grade of bearing grease. Install the balls, imbedding them into the grease.

There are 19 balls in the upper race and 20 in the lower race.

4. Install the steering stem into the frame lug, fit the upper inner race and cap.

5. Install and tighten the steering stem locknut to 19.5–24 ft lbs. Check bearing play. Refer to the "Bearing Adjustment" section, above.

Position the legs so that the tops are about 200 mm (7.9 in.) above the lower triple clamp

6. Install the fork legs. The legs should be positioned so that their tops are about 200 mm (7.9 in.) above the lower triple clamp. Tighten the triple clamp pinch bolts temporarily to hold the fork legs in place.

7. Install the rubber damper, damper ring, base cover, fork cover, and ring cap (in that order).

8. Install the upper triple clamp, the lockwasher, and flat washer (flat side facing down). Screw on the stem head bolt loosely. Be sure that the wiring harness and the cables go in from of the stem head.

9. On KZ650-B models, loosen the lower triple clamp bolts, and align the upper surface of the top bolt flange flush with the upper surface of the upper triple clamp. Tighten the upper clamp bolts to 11.5–16.0 ft lbs.

10. For the KZ650-C/D, slide each fork leg up until the end of the tube is about 2 mm (0.08 in.) below the top surface of the upper triple clamp.

11. Tighten the stem head bolt to 29–36 ft lbs. Tighten the rear clamp bolt to 11.5–16.0 ft lbs.

12. Tighten the lower triple clamp pinch bolts to 25–33 ft lbs.
13. Install the handlebars.
14. Install the master cylinder and calipers.
15. Install the brake line joint. Be sure that the cable guide is included with each bolt. Tighten the bolts to 5.1–6.5 ft lbs.
16. Install the instruments. Be sure that the left switch wiring harness and the right switch wiring harness run between the upper triple clamp and the instruments. Note the rubber dampers fitted both above and below the triple clamp.
17. Afix the instrument cables.
18. Connect the front brake light switch. The wires may be connected to either terminal.
19. Run the plugs and wiring into the headlight shell. Install the turn signals. Connect the turn signal leads. The left turn signal takes the green lead. The right takes the grey lead. Both black/yellow leads are connected to the black/yellow plug.
20. The remainder of the procedure is the reverse of removal.

HANDLEBARS

Removal

1. Remove the mirrors.
2. Remove the gas tank.
3. Disconnect and remove the throttle cables. This is done by running the cable adjusters in as far as possible, splitting the twist-grip, and disconnecting the throttle cables from the drum.
4. Slide the rubber cover aside and disconnect all of the leads from the switch housings. The lead connectors are under the frame top tubes.
5. Remove the clutch adjusting cover. Loosen the locknut and back out the clutch adjusting screw several turns. Run the clutch cable adjuster at the handlebar in as far as possible and disconnect the cable from the hand lever.
6. Using a small screwdriver, press in the starter lockout switch tab which catches in the hole on the underside of the clutch lever holder. Remove the switch.
7. Remove the master cylinder.
8. Remove the handlebar clamp bolts and remove the handlebars.

Installation

1. Run the wiring leads between the upper triple clamp and the instrument holder. Fit the handlebars.
2. Tighten the clamp bolts to 11.5–16.0 ft lbs. The bars should be angled slightly away from the center line of the front forks.
3. Tighten the master cylinder bolts to 4.3–6.5 ft lbs. Note that the clamp is installed with the small projection towards the throttle twist-grip.
4. Connect the wiring. Note that one of the starter locknut black leads is connected to a black lead of the main wiring harness, while the other black lead is connected to the black lead from the right switch housing on the handlebar.
5. The remainder of the procedure is the reverse of removal. Adjust the clutch, clutch cable, throttle cables, etc.

REAR SHOCK ABSORBERS

Removal

1. Park the motorcycle on the centerstand.
2. Remove the mufflers.
3. Remove the grab bar mounting bolt.
4. Remove the cap nut from the top of the shock absorber. Remove the grab bar.
5. Lifting up the rear wheel as necessary, remove the lower shock bolt. Remove the shock.

Inspection

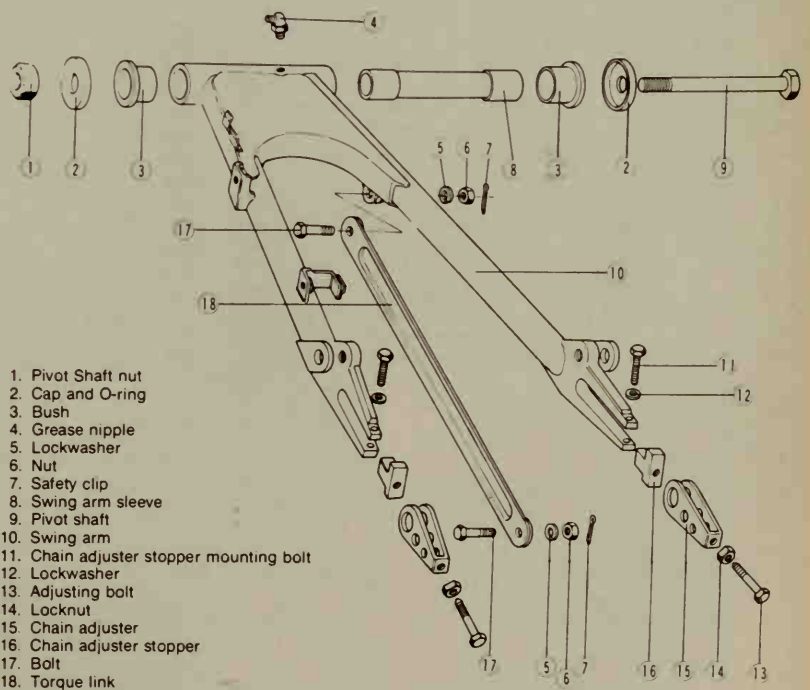
1. The shock absorbers are sealed units, and cannot be disassembled for repair. If defective they must be replaced. Always replace shock absorbers in pairs, even if only one is damaged, to ensure even operation. Riding the motorcycle with unequally operating shocks may cause instability.
2. If the shocks leak oil, or if they were damaged in an accident, replace them. Check for dents in the damper unit, or a bent damper rod.
3. Compress each shock as far as possible and release it. The shock should return smoothly to its full length. If the shock snaps back suddenly, the damper unit is defective and the unit should be replaced.
4. If one shock feels weaker than the other when compressing it, replace both.
5. Check the rubber bushings at either end of the unit and replace them if they are cracked or hardened.

Installation

Installation is the reverse of removal. Tighten the lower shock bolt to 19–25 ft lbs. Tighten the upper cap nut to 19–25 ft lbs.

SWING ARM

Inspection



1. Place the motorcycle on the centerstand.
2. Remove the mufflers.
3. Remove the rear wheel. For disc rear brake models, disengage the brake hose from the swing arm guides and hang or support the caliper so that it does not pull on the brake line.
4. Unbolt the shock absorbers from the swing arm.
5. Check the swing arm by moving it slowly up and down. There should not be abnormal friction.
6. Grasp both swing arm tubes and attempt to move the swing arm from side-to-side. There should be no lateral play.
7. If there is lateral play, or abnormal resistance to vertical swing arm movement, the swing arm bushings should be replaced.

Removal

1. Proceed as outlined above, Steps 1–4.
2. Remove the pivot shaft nut and pull out the pivot shaft.
3. Remove the swing arm from the machine. The dust cover on each side of the swing arm will come off.

Disassembly

1. Swing arm bushes, once removed, must be replaced with new ones. Have the new ones on hand prior to disassembly. If the condition of the bushes is questionable, measure their inside diameter in place on the swing arm.
2. Remove the safety clip from the torque link bolt. Remove the nut and bolt and separate the torque link from the swing arm.

Swing arm components

3. Remove the swing arm sleeve.

4. Insert a suitable bar or rod through the swing arm and knock out the bush on the other side. Remove the remaining bush in the same manner.

Inspection

1. Measure the outside diameter of each end of the swing arm sleeve. Standard diameter is 21.979–22.00 mm (0.8653–0.8661 in.). The sleeve should be replaced if the measured diameter is less than 21.95 mm (0.864 in.).

2. Unless the bushes have been removed, in which case they must be replaced in any event, measure the inside diameter with a cylinder gauge. Standard ID is 22.055–22.088 mm (0.8683–0.8686 in.). Replace the bushes if the measured diameter is greater than 22.29 mm (0.878 in.).

3. To measure the swing arm pivot shaft run-out, mount the shaft in a set of v-blocks and measure run-out with a dial gauge set in the middle of the shaft.

In this case, run-out is the total amount of gauge movement. Standard run-out is under 0.1 mm (0.004 in.). The shaft should be replaced or straightened if run-out exceeds 0.14 mm (0.006 in.). If run-out exceeds 0.7 mm (0.028 in.), or if the shaft cannot be straightened, it must be replaced with a new one.

Assembly

1. Assembly is basically the reverse of disassembly. Note the following points:

a. Oil the new bushes before driving them into place with a press. Be sure that the bushes are properly seated.

b. Clean off all the old grease from the swing arm sleeve and lubricate it with fresh chassis grease. Be sure to grease the grooves especially.

c. Tighten the torque link nut to 19–25 ft lbs., and install the safety clip.

Installation

1. Be sure that the dust caps are in place on either end of the swing arm before installation.

2. Put the left side of the swing arm through the drive chain.

3. Insert the pivot shaft from the right side. Tighten the pivot shaft nut to 58–87 ft lbs.

MAINTENANCE

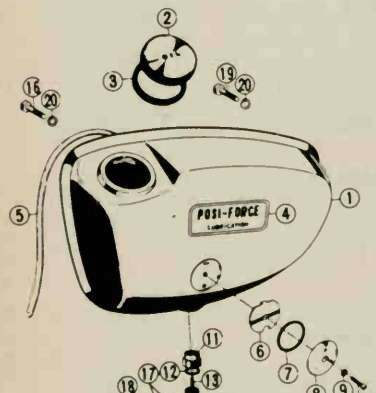
NOTE: *Common maintenance procedures are explained in detail in "General Information."*

LUBRICATION

Engine

The engine top end and crankshaft are automatically lubricated by the Suzuki "CCI," or "Posi-Force," system. Periodically check the oil tank by means of the inspection glass, and add CCI oil when needed.

Always use Suzuki "CCI" oil for engine lubrication. If it is not available, a high-grade two-stroke oil around SAE 30W viscosity may be used instead.



At extended intervals (about 4,000 mi), remove and clean the filter fitted to the oil tank outlet.

The oil pump cable adjustment should also be checked. Refer to "Service Checks and Adjustments."

Transmission

The transmissions are lubricated by an oil bath. SAE 20W/40 oil is recommended for all models. Recommended change interval is 2000 miles, and the oil capacity for each model are given in the charts at the end of this section.

1. The transmission oil should be changed when warm.

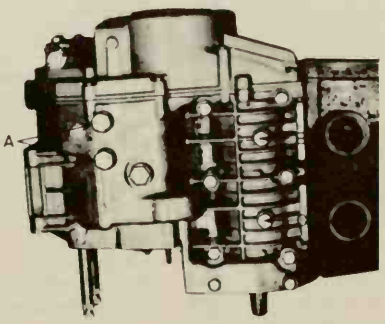
2. Remove the drain plug(s) at the bottom of the crankcase and allow the oil to drain for about five minutes.



NOTE: *Twin-cylinder models may have two drain plugs, and both should be removed. Some twins have a drain plug for the crank chamber also. Models with the low, motocross-type pipe will have the drain plug on the right-side of the engine near the bottom (see illustration).*

The plug indicated is the shift drum guide (TS-250); the drain plug on the left

Removing the transmission oil drain plug (TS-125)

Transmission drain plugs (A), and crank chamber plugs (B and C) (T-125)

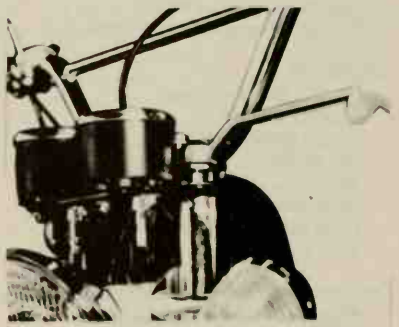
3. Check the condition of the drain plug gasket, and replace if necessary. Be certain that the plug(s) are firmly secured when refitted.

4. Remove the filler plug and add the correct quantity of oil to the transmission. Check the oil level with the dipstick (if so equipped), or with the level plug fitted to the right-side of the crankcase. If the level is correct, oil will begin to seep out of this hole when the plug is removed. When checking the oil level, ensure that the machine is parked on a flat surface and is positioned vertically. After adding oil, allow a few moments for the oil to distribute itself before checking the level.

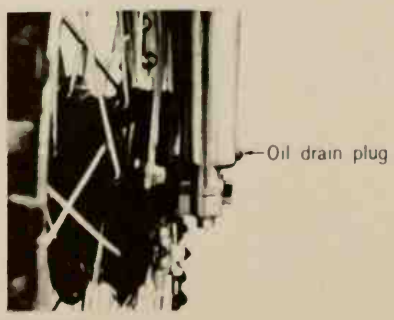
Forks

Refer to the charts at the end of this section for fork capacity and recommended oil; oil change interval is 8000 miles or annually.

Checking oil level (GT-185), maintain level between the "L" and "F" marks



Oil level inspection screw (T-125)



1. To drain the fork oil, remove the phillips head drain plug at the bottom of either fork slider.

2. Turn the forks all the way to the right to drain the right fork leg and to the left for the left fork leg.

3. After the oil has been allowed to drain for several minutes, pump the forks up and down to ensure that all the oil has been expelled. Replace the drain plug, and repeat the procedure with the other fork leg.

Removing the fork leg top bolt

4. To add oil, support the front wheel off the ground and remove the top bolts at the top of each fork leg; add the correct, measured quantity of oil to each fork leg.

Note that oil viscosity can be varied slightly to change the fork dampening characteristics, a heavier oil giving a stiffer fork action, and vice versa.

5. After adding the oil, replace and tighten the fork crown nuts securely. Tightening torque, on most models, will be 15–20 ft lbs.

SERVICE CHECKS AND ADJUSTMENTS

Drive Chain

1. The chain should have about 15–20 mm (0.6–0.8 in.) of total up-and-down slack measured in the middle of the lower chain run.

2. *Before* checking or adjusting the chain slack, the following conditions should be met:

a. the machine should be on the center stand or unladen;

b. the chain should be clean and well lubricated;

c. the real wheel should be rotated slowly while checking the chain for any tight spots. If a tight spot exists, the chain tension should be adjusted to the proper value at the tight spot.

3. To adjust the chain, back the rear brake adjustment off several turns. Loosen the axle nut. Loosen the locknut on each adjuster bolt.

4. Turn each of the adjuster bolts in by equal amounts until chain tension is approximately correct.

5. Check the wheel alignment by means of the adjusting marks inscribed on the swing arm. Be sure that both adjusters are lined up with the corresponding marks on either side of the swing arm. If not, turn one of the adjuster bolts in or out until alignment is achieved.

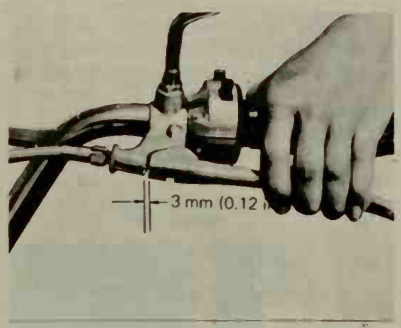
6. Tighten the axle nut and check the chain tension. Correct if necessary. After adjustment is correct, tighten the adjuster bolt locknuts and adjust the rear brake.

7. Before putting the machine in service, check that sufficient slack exists with a rider on the machine.

Clutch

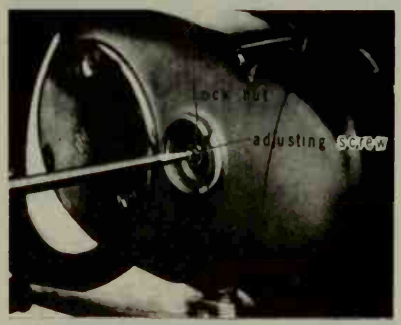
F50 models use an automatic clutch which needs no maintenance. On all other models, clutch cable adjustment should be made to give 3–4 mm (0.12–0.16 in.) of free-play at the lever as shown in the illustration.

Maintain this free-play with the cable adjuster on the crankcase. Minor adjustments can be made with the adjuster on the clutch lever if one is fitted. If lever free-play is too great, the clutch will not completely disengage; if it is too little, the clutch lever if one is fitted.



If proper clutch operation cannot be obtained although the cable is correctly adjusted, the clutch release mechanism should be set. The following procedure is applicable to all manual clutch models except for those with the rack-and-pinion clutch.

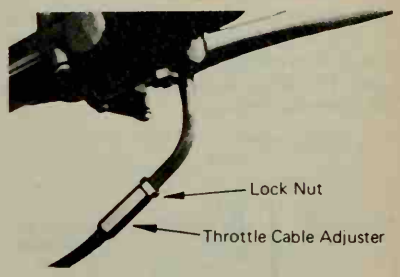
1. Remove the clutch release mechanism cover or plug, depending on model.



2. Loosen the crankcase clutch cable adjuster locknut and screw the adjuster in until slack appears in the cable.

3. Turn the adjuster out until the slack is taken up, but no farther (i.e., do not put tension on the cable).

4. Loosen the clutch adjuster locknut, and back off the adjuster with a screwdriver.



Measure clutch lever free-play between the lever and the holder as shown

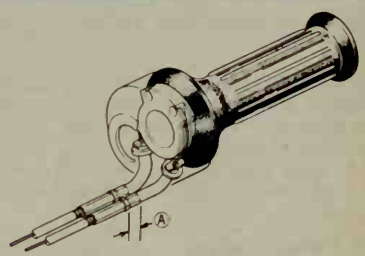
Adjusting the clutch

Adjusting the clutch cable

Throttle cable adjuster

5. Turn the adjuster screw in until resistance is felt, then back it off ½ turn and retighten the locknut.

6. Set the cable free-play at the handlebar lever as described above.

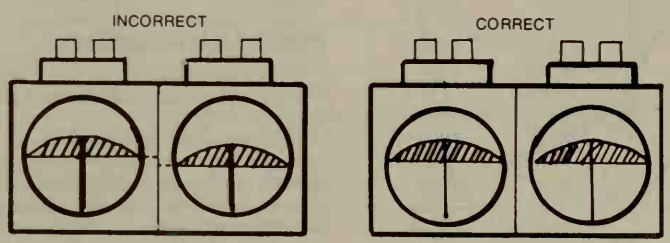


NOTE: *The TS400 and TS125, 185 and 250 "A" models use a rack-and-pinion release mechanism unlike the worm gear and lever arrangements of the other machines. The clutch cable only need be adjusted.*

Throttle Cables

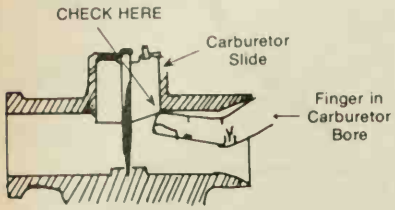
Throttle cables should be set to have 0.5–1.0 mm (0.02–0.04 in.) of slack measured from the end of the cable sheath to the adjuster.

1. On single-cylinder machines, the adjustment can be made with either the twist-grip or the carburetor cap adjuster.



On late model single-cylinder machines with the positive-action dual-cable pulley set-up, adjust *both* cables to the specified play.

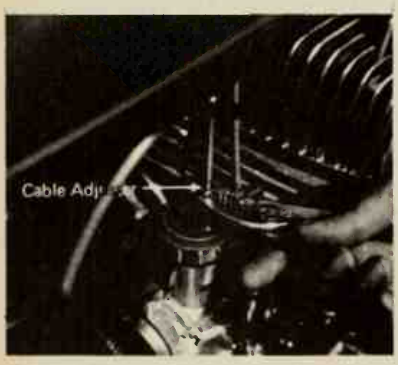
On dual-cable carburetors, set both cables to 0.5–1.0 mm (0.02–0.04 in.) of slack (A)



2. On twins, each cable must be set to the above specification using the adjuster atop each carb. Then check that the throttle slides are synchronized. Both must begin to move at the same time. The air cleaner must be removed to check this adjustment.

Another synchronization method is to insert your fingers into the carburetor bores to ensure that both throttle slides

Throttle slide synchronization (twins)



clear the bore at the same time. You will be able to feel when one slide becomes just flush with the uppermost part of the bore. The other slide must be in exactly the same position.

One method for checking that the slides are properly synchronized

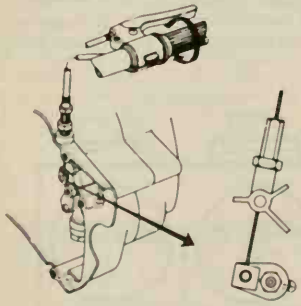
After synchronizing the slides, set the twist-grip adjuster to give 0.5–1.0 mm (0.02–0.04 in.) of cable slack.

3. Check throttle cable adjustment by starting the engine and turning the handlebars from lock-to-lock, noting any

Adjusting the throttle cable with the carb cap adjuster

variation in rpm. If this occurs, the cable(s) are too tightly adjusted or are binding somewhere along their route. Readjust as necessary.

4. After adjusting the throttle cable, the oil pump cable must also be adjusted.



Oil Pump Cable

This procedure must be done after adjusting the throttle cable(s). Note the different methods for each model.

PISTON-PORT SINGLES

Type 1

1. Remove the engine sprocket cover and the oil pump cover located beneath it. On TS250 models, remove the pump cover on the right engine cover only.

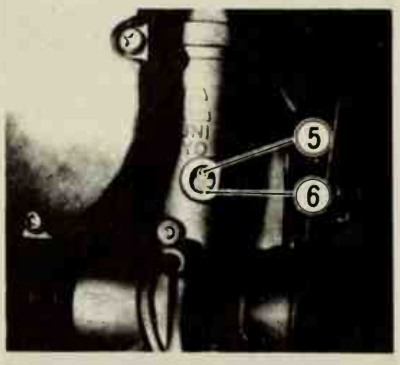
Oil pump lever adjustment

2. Turn the throttle wide-open. Note that the alignment marks on the oil pump body and oil pump control lever should line up.

3. If the marks do not align, use the oil pump cable adjuster to correct them.

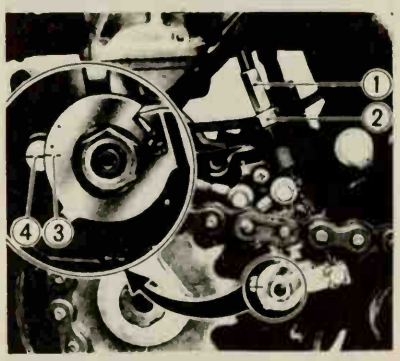
Type 2

"Type 2" refers to late model single-cylinder machines which have an inspection plug on the carburetor body for the oil pump cable adjustment.



1. Remove the engine sprocket cover to gain access to the oil pump.

2. Remove the inspection plug from the right side of the carburetor.



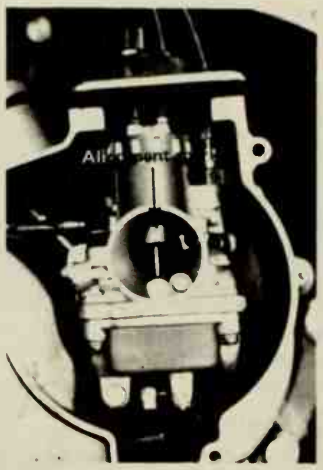
3. Twist open the throttle until the throttle slide punch mark becomes visible, then align the very top edge of the punch mark with the top of the carburetor inspection hole.

4. At this point, the oil pump control lever and body marks should be aligned.

5. If they are not, use the oil pump cable adjuster so that the marks align.

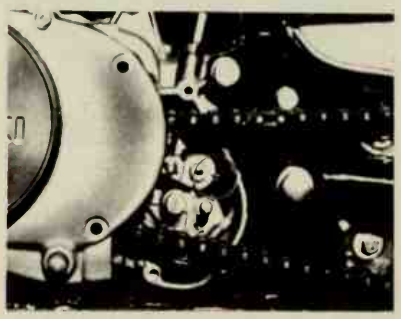
Late-model singles may have an inspection plug for the oil pump cable adjustment. When the punch mark (5) is aligned with the top of the inspection hole (6) . . .

. . . the oil pump lever and body marks (3 and 4) must align. Use the cable adjuster and locknut (1 and 2) to make adjustments



ROTARY VALVE SINGLES

1. Remove the engine sprocket cover and the oil pump cable located beneath it.



2. Remove the carburetor cover.

3. Noting the punch mark on the throttle slide, turn the throttle so that this mark just touches the upper part of the carburetor bore.

4. With the throttle held in this position, the mark on the oil pump body should align with that on the oil pump control lever. If necessary, use the pump cable adjuster to bring them into alignment.

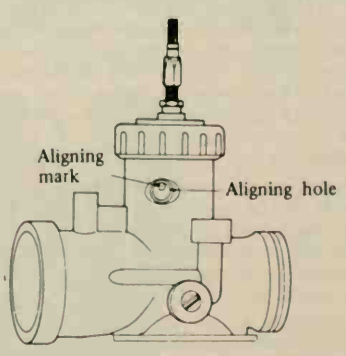
Aligning the pump lever marks



5. If no punch mark is provided on the throttle slide, adjust the oil pump cable as described for Piston-Port Singles, "Type 1," Steps 2 and 3.

GT185 AND GT250

1. Remove the oil pump inspection plug (GT250) or cover (GT185).

2. Remove the inspection plug from the body of the right-hand carburetor.

3. Open the throttle until the punch mark on the throttle slide is just at the top of the carburetor aligning hole.

4. With the throttle held in this position, the marks on the oil pump body and the oil pump control lever should line up. Use the oil pump cable adjuster to correct adjustment, if necessary.

OTHER TWINS

1. Remove the oil pump inspection plug or cover.
2. Turn the throttle fully open.
3. With the throttle in this position, the marks on the oil pump body and the oil pump control lever should align.
4. If they do not, use the pump cable adjuster to make the correct adjustment.

BRAKES

FRONT DISC

1. No adjustment is necessary other than a check on brake fluid level and pad wear.
2. The fluid level in the handlebar-mounted reservoir should be maintained at ½ in. below the top of the reservoir. This level can be checked after removing the reservoir cap and diaphragm. On newer models, the level is marked on the see-through reservoir and the cap need not be removed. Maintain the level between the "upper" and "lower" lines.
3. Pads should be checked periodically for wear, and should be replaced when worn to near the red limit line.
4. The brake hoses should be checked for seepage or abrasion damage often, and should be replaced in either of the above cases. Also make sure that the brake line touches the forks only at the junction or mounting points.

Twin-leading shoe front brake rod adjustment

FRONT DRUM

Use the adjusting nut at the brake hub so that the brake lever will move 20–30 mm (0.8–1.2 in.) before the brake shoes fully contact the drum.

On twin-leading shoe brakes, the brake hub connecting rod should normally not need adjustment. If it is felt that adjustment is necessary, however, proceed as follows:

a. Loosen the connecting rod locknut, and turn the connecting rod so that the distance between the two brake levers is decreased as much as possible.

b. Use the handlebar brake lever to apply the brakes. This will cause the shoe controlled by lever "a" in the illustration to contact the drum.

c. While holding the brake on, turn the connecting rod to increase the distance between the two levers. The connecting rod will stop turning when the brake shoe controlled by lever "b" contacts the drum, and at this point the brake shoes are adjusted. Do not forget to adjust the cable.

REAR BRAKE

Use the adjusting nut on the rear brake hub to give 20–30 mm (0.8–1.2 in.) of brake pedal travel before the shoes fully contact the drum.

REAR BRAKE LIGHT SWITCH

The point at which the rear brake light is activated may be adjusted by means of the locknut on the switch to suit personal preference, although the light should be on before the brakes are fully applied.

Air Cleaner

1. If a paper element air cleaner is fitted, brush dirt deposits off with a stiff brush or blow them off with compressed air applied to the inside of the filter. Paper filters, however, are best replaced with new ones when dirty.

2. If a foam-type air cleaner is used, wash it in gasoline to remove dirt, and squeeze until it is dry. Immerse the filter in light motor oil (20 or 30W) or Suzuki CCI oil and squeeze off the excess oil. Then install on the machine.

Steering Head Bearings

1. Steering head bearing adjustment should be checked periodically and adjusted if necessary. Refer to the "Chassis" section.

TUNE-UP

NOTE: *Common tune-up procedures are explained in detail in "General Information."*

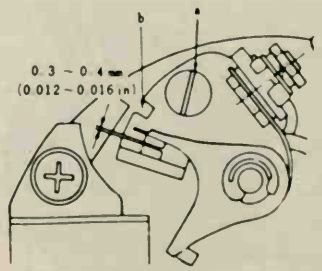
CONTACT BREAKER POINTS

Location

1. On single-cylinder machines, the breaker points are located beneath the magneto flywheel on the left-side of the engine. Remove the points cover or the forward section of the left-side engine cover (depending on model) to gain access to the points. Cutouts are provided in the flywheel to allow the points to be cleaned and gapped.

2. Twin-cylinder machines have two sets of points which run off the left-side of the crankshaft. The points are accessible for cleaning and gapping or replacing after removing the point cover on the left engine cover, or the forward section of the left engine cover (depending on model).

Gapping



SINGLES

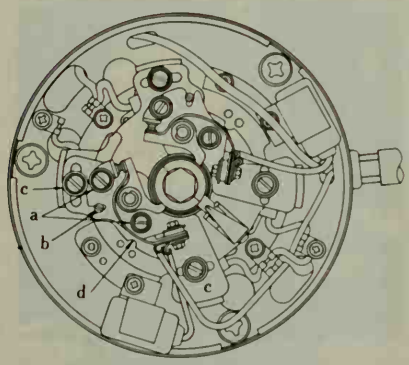
1. After removing the engine cover to gain access to the magneto flywheel, turn the flywheel so that the breaker points are visible through one of the cutouts.

2. Position the flywheel so that the breaker points are fully open, then check the gap with a feeler gauge. Proper point gap is 0.3–0.4 mm (0.012–0.016 in.).

Checking the point gap (magneto models)

To adjust the gap, loosen screw "a" and move the point plate with a thin screwdriver blade applied at "b" (magneto models)

3. If the gap is not within specification, refer to the accompanying illustration. Loosen the securing screw "a" and insert a thin screwdriver into the slot "b," turning the screwdriver blade as necessary to increase or decrease the point gap.



4. Retighten screw "a" and recheck the gap.

TWINS

1. After removing the breaker point cover plate, rotate the engine so that either set of points is fully open.

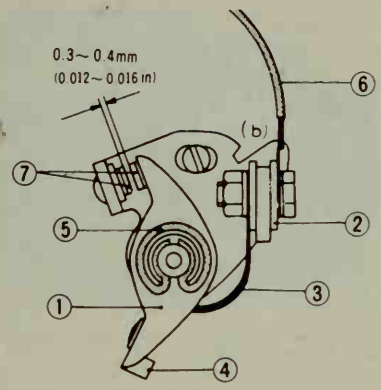
2. Check the gap with a suitable feeler gauge. Gap should be 0.3–0.4 mm (0.012–0.016 in.).

3. If the gap is not within specification, refer to the accompanying illustrations, depending on the type of points fitted. On newer models, loosen both securing screws marked "a," and then use eccentric screw "b" to adjust the gap. Retighten the securing screws and recheck the point gap. Rotate the engine until the other set of points is open, and repeat the procedure.

To adjust the gap on twins with this type of point assembly, loosen screws marked "a" and turn the eccentric screw "b." Screws "c" are used to change the timing

On older models, setting the point gap is done is the same manner as described for the single-cylinder machines. Refer to Steps 3 and 4, above. Remember to gap and check both sets of points.

Replacement



SINGLES

Two special tools are needed to replace the points on single-cylinder machines. A flywheel holder is used to hold the magneto flywheel steady while the nut is removed, and a special puller, threaded into the center of the flywheel, is needed to pull it off its tapered shaft.

CAUTION: *The flywheel puller is essential for this job.*

Removing the magneto flywheel with the special holder and puller

Breaker point components

1. Contact breaker arm
2. Insulator
3. Spring
4. Cam follower
5. Circlip
6. Primary wire
7. Contact breaker points

1. Remove the left-side engine cover. On some models it may be necessary to take the gearshift lever off its shaft.

2. Holding the magneto flywheel with the special tool, or a suitable substitute, loosen and remove the flywheel nut.

3. Using the special puller, as shown, remove the magneto flywheel. Note the location of the woodruff key on the crankshaft.

CAUTION: *After removal, put the flywheel in a safe place. Avoid dropping or striking the flywheel as this may affect its magnetic properties.*

4. Disconnect the primary wire from the breaker point, and then remove the securing screw. Remove the old points, install the new ones, and connect the wire.

NOTE: *Before installing new points, clean the contact surfaces with a solvent to remove any protective coating.*

5. Carefully replace the flywheel on its shaft. Note that the shaft is keyed so that the flywheel must be aligned with the key before it is installed. It is possible to simply push the flywheel into position. Do not strike or attempt to drive it on.

6. Replace the rotor nut and torque it to 25–35 ft lbs on machines up to 125 cc, and 35–45 ft lbs on larger bikes.

7. Set the point gap and check or adjust the ignition timing.

TWINS

1. Remove the breaker point cover.

2. Replace the points one set at a time. Disconnect the point primary wire, and remove the securing screw or screws.

3. Before installing new points, be sure to clean off the breaker point surfaces with a solvent to remove any protective coating.

4. After installing each set, adjust the point gap and set the ignition timing.

Lubrication

1. Whenever the point gap is checked or points replaced, it is necessary to lubricate the cam follower and the pivot point of the contact breaker. This minimizes wear and ensures that timing will remain accurate for a longer period. A worn cam follower will retard the timing.

2. A small dab of high melting-point grease should be applied to the breaker cam. A drop of engine oil should be applied to the pivot point.

3. In both these instances it is imperative that care be taken to keep the lubricant away from the points.

4. Models which have a lubricating felt pad fitted should have this felt adjusted so that it just contacts the breaker cam.

IGNITION TIMING

On most models, there are several methods of adjusting the timing, depending on the type of equipment available.

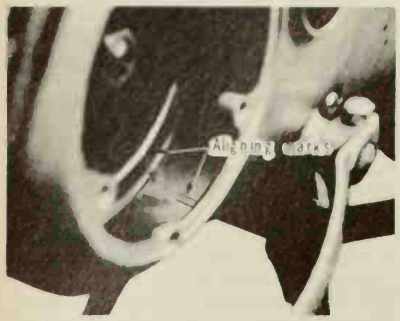
a. Since timing marks are fitted to all models, a strobe light of the type generally used on automobiles can be used. This is the easiest method, and is the only method which can be used on PEI models.

b. There are two methods of static timing. The preferred one involves the use of an instrument to determine when the points open, and a dial gauge which is inserted in place of the spark plug to determine piston position.

For twin-cylinder machines, which use a battery and coil ignition, a test light or continuity light can be used to find the point at which the points open.

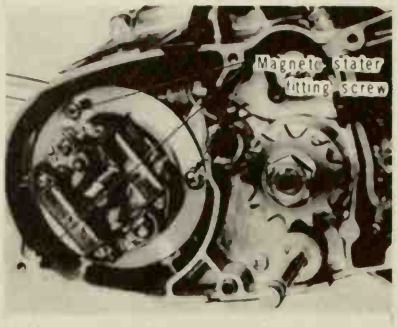
Single-cylinder machines using the magneto flywheel are best timed with a "point checker," or ohmmeter instead of a test light due to the construction of the magneto.

c. A second static timing method does not require a dial gauge, but does require a test light or ohmmeter. This method involves lining up scribed lines on the flywheel or breaker point plate, the locations of which are discussed below.



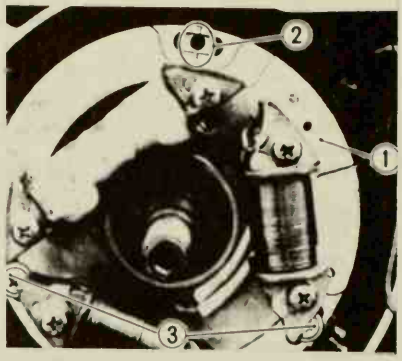
NOTE: *Points must be cleaned and gapped before checking timing. Dirty points will cause inaccurate results.*

Singles (Except PEI Models)

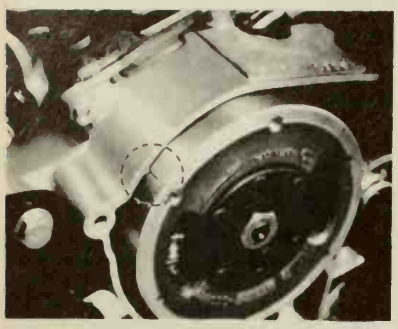


NOTE: *With the exception of older 50 cc models, ignition timing can only be adjusted by adjusting the breaker point gap. On older 50 cc models, the timing may be adjusted, after removing the magneto flywheel, by moving the breaker point plate.*

1. If a strobe light is used, connect it to the spark plug and to a battery or other power source depending on the type of light used. Be sure to follow the manufacturer's instructions. If a battery is used, be certain the strobe light leads are connected to the proper terminals.



2. Start the engine, shining the strobe light on the magneto flywheel. The tim-



Ignition timing marks (F-50)

Timing can be adjusted by moving the stator on some early 50cc models

The timing mark on the stator (2) must align with the center of the screw hole. If necessary, loosen the stator screws (3) and rotate it to achieve alignment

Timing marks on the case and magneto flywheel must align (magneto models)

ing pointer on the crankcase and the scribed mark on the flywheel must align. Refer to the illustrations provided for the location of these timing marks on the various models.

3. If the marks do not align, alter the point gap so that proper timing is achieved.

NOTE: *If the flywheel mark is above the crankcase pointer, the timing is too advanced, and the point gap must be reduced. If it is past the crankcase pointer, the timing is too retarded, and the gap should be increased.*

On older 50 cc models, the flywheel can be removed to adjust timing. Loosen the three screws which secure the contact breaker plate (stator) and move the plate counterclockwise if the timing was too advanced, or clockwise if it was too retarded. Recheck timing after installing the flywheel.

4. If a static timing method is being used, hook up the point checker leads in the following way: the negative lead may be connected to a good ground on the engine or frame. The positive lead should be connected to the breaker point primary wire or to the spring of the movable point. Refer to the breaker movable point. Turn the engine until the points are closed.

5. Turn the flywheel slowly in the normal direction of rotation. Stop at the very instant your checking device reacts. Then note the timing mark on the flywheel and pointer on the crankcase. The two should be exactly aligned. If they are not, adjust the point gap, or breaker base plate on early 50 cc machines, until proper timing is achieved. See Step 3, above, for more information.

After setting the gap, recheck the timing.

NOTE: *Although it is not guaranteed to give good results, the point at which the contact breakers open can also be determined with a very thin piece of paper or cellophane. Trap the paper between the closed points, and tug lightly at it while rotating the flywheel. When the paper is freed, the timing marks should be lined up, as above.*

This method can be used in emergency situations.

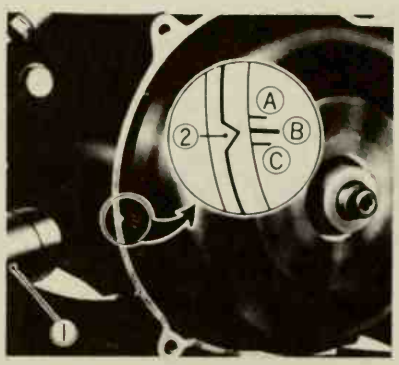
6. The use of the dial gauge and point checker yields the most accurate results. Remove the spark plug, and install the dial gauge. Hook up the point checker as described in Step 4. Turn the engine over by hand until the gauge peaks and begins to reverse direction. By turning the engine back and forth several times until the gauge needle is accurately positioned at the highest indicated value, the piston will have been positioned at Top Dead Center. Zero the gauge at this point.

7. Refer to the chart at the end of this section for timing specifications expressed in millimeters BTDC for your machine.

8. Turn the engine clockwise so that the piston is about 4 mm BTDC. Then turn it slowly in the normal direction of rotation. When the dial gauge indicates that the piston is at the firing point given in the "Tune-Up Specifications" chart, the point checker should react indicating that the points have opened.

If the points do not open at the correct time, adjust the gap as outlined in Step 3, above.

PEI Singles



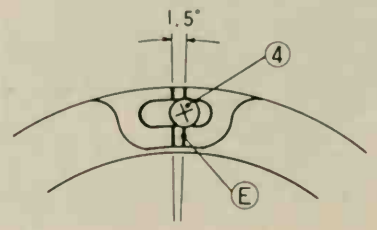
PEI equipped models must be timed with a strobe light. Static timing is not possible. If timing is not spot-on, the coil mounting plate beneath the magneto flywheel must be moved. To remove the flywheel a special puller is needed, as well as a device to hold the flywheel while the nut is being removed.

1. To check the timing, remove the left-side engine cover.

2. Hook up the strobe light according to the manufacturer's instructions. This will vary depending on the type used.

3. Start the engine and run the rpm up to 3,000 on the TS-400, 4,000 rpm on the other models. The timing marks on the flywheel and the crankcase must align.

On most models, there is one long flywheel mark flanked by two shorter



Dynamic timing should show the crankcase mark (2) between timing marks "A" and "C", preferably at "B"

marks. Alignment of the crankcase mark with the longer middle mark is preferred, but timing anywhere between the marks is acceptable.

4. If timing is not correct, use the flywheel holder to keep it steady, and remove the nut. Use the puller to remove the flywheel from the tapered shaft. Note the woodruff key on the crankshaft.

5. Loosen the three screws which secure the coil plate (stator) just enough to enable the plate to be moved. The uppermost securing screw should be removed completely. Referring to the accompanying illustration, align the mark on the stator with the center of the securing screw hole. If two stator marks are there, align the right-hand mark with the center of the screw hole. Tighten the three securing screws; install the flywheel, carefully aligning it with its key, and replace the nut being sure that it is firmly tightened. Torque it to about 40 ft lbs.

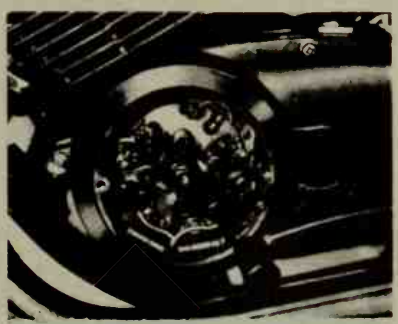
If two stator marks are found, align the stator mark (E) with the center of the screw (4)

NOTE: *The flywheel must be installed on the crankshaft by hand. Never attempt to drive it on or strike it.*

6. Recheck the timing with the strobe light.

Twins (Except GT-500A)

Twins are equipped with battery-and-coil ignitions and use two sets of points. The right-hand points fire the right cylinder. Timing mark location varies with model.



1. Remove the point cover.
2. After cleaning and gapping the points, proceed with one of the procedures outlined below.
3. If a strobe light is being used, connect it according to the manufacturer's instructions. Start the engine and note that the timing marks should line up.

NOTE: *GT models have the timing marks on the breaker cam and these will align with a pointer (see illustration). Other models will have the marks on the rotor (behind the breaker plate) and a small inspection window is provided.*

4. If the marks fail to align, loosen the two setscrews for the set of points you are checking, and move the points slightly counterclockwise to retard or clockwise to advance the timing.

Timing marks (GT-185)

Timing marks (T250-350)

NOTE: *"Advance" or "retard" is determined relative to the rotation of the crankshaft. If the moving timing mark is positioned to the right of or below the stationary pointer, the timing is too advanced. If positioned to the left or above the pointer, it is too retarded.*

5. Recheck the timing after adjustment. Repeat the procedure with the other set of points.

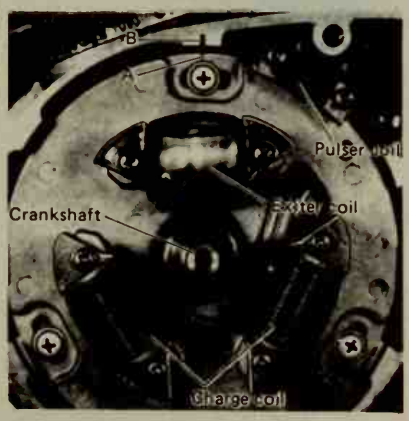
6. Static timing is possible with a dial gauge and point checker, or with a test light.

If a dial gauge is available, install it in place of one of the spark plugs. Hook one lead of the test light or checker to the primary wire of the correct point set and the other to ground on the engine or frame.

7. Determine piston Top Dead Center with the dial gauge by turning the engine over slowly until the gauge needle peaks and begins to reverse. The highest needle reading indicates piston TDC.

8. Refer to the specifications chart at the end of this section for the correct timing specs in millimeters BTDC for your model. Zero the gauge, and turn the engine backwards about 5 mm BTDC. The points should be closed at this piston position. Turn the engine in the normal direction of rotation (counterclockwise).

When the dial gauge indicates the firing point given in the "Tune-Up Specifications" chart has been reached, the points should begin to open as indicated by the reaction of the test light or meter.



If necessary, adjust the points as described in Step 4. Repeat the procedure with the other set of points and with the dial gauge in the other cylinder. After adjusting the points, recheck the timing.

9. If no dial gauge is available, the timing can be set by using the marks on the breaker cam or rotor along with a test light. The procedure is essentially the same as described above with a strobe light, except that the engine is turned by hand.

After hooking up the test light, turn the engine over slowly until the timing marks for the cylinder you are checking line up. At this point the test light will react. If it does not, adjust the point set as described in Step 4. Repeat with the other set of points.

GT-500A

1. The GT-500A (1976) is equipped with PEI.
2. To check the timing, remove the leftside engine cover to gain access to the magneto flywheel.
3. If the crankcase mark is aligned

GT-500A alignment marks (A and B) and PEI components

GT-500A flywheel timing marks

with the mark on the stator, the timing is correct. It is not necessary to remove the magneto flywheel to check this alignment.

4. To check the timing dynamically, connect a strobe light according to the manufacturer's instructions.

NOTE: *It does not matter which spark plug the strobe is connected to, as there is only one ignition coil.*

5. Start the engine and run it to about 3000 rpm. At this speed, the marks on the magneto flywheel will align with the crankcase mark.
6. If adjustment is necessary, remove the flywheel with the puller, loosen the three stator plate screws, and move the plate so that the stator mark and crankcase mark are in alignment as outlined in Step 3.

CARBURETOR

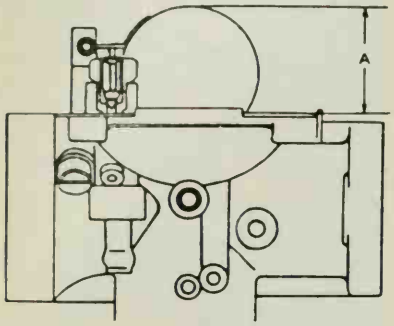
Three adjustments to be made to the carburetor are float height, idle mixture, and idle speed.

Adjusting Float Height

There are three different methods of measuring the float height, depending on model year and the type of carburetor fitted.

The first method is used exclusively on carburetors with interconnected (one-piece) float assemblies. On these models, the floats are soldered to the float arm which makes this type easily identifiable. This is Method "A."

The remaining two methods are used on carburetors which have independent floats.



Method "B" measures float height from the float arm to the top of the needle jet fitting boss.

Method "C" measures float height from the float bowl mating surface (gasket removed) to the float arm.

NOTE: *Float height measurements will be inaccurate if the float needle is worn, or if the needle or needle seat are dirty or corroded.*

INTERCONNECTED FLOAT TYPE

Most models use this type of float system. For those which do not, see "Independent Float Type."

Carburetor float height, Method "A"

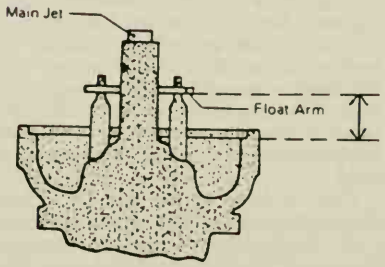
1. Remove the carburetor(s).
2. Turn the carburetor upside down, and remove the four float bowl screws carefully lifting off the float bowl.
3. Remove the float bowl gasket.
4. Float height can be measured with a steel rule or a vernier caliper. Float height is defined as the distance from the float bowl mating surface to the bottom of the float, when the tang of the float arm is just touching the float needle; measurement "A" as shown in the illustration.

NOTE: *Lower the float down until the tang just contacts the float needle. Hold the float in this position, then measure the float height.*

5. Compare the value obtained with the correct specification for your machine given at the end of this section. If the float height is too high or low, pull out the pin which holds the float in place, and bend the tang very slightly to correct the adjustment.

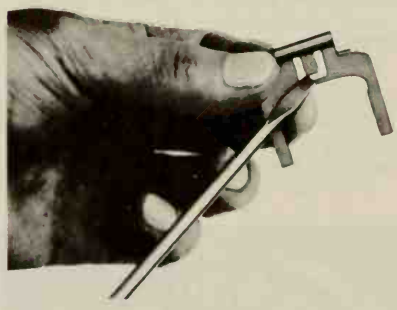
NOTE: *If float height is too high, bend the tang away from the carburetor body. If too low, bend it toward the carburetor body.*

6. Refit the float and recheck the adjustment.



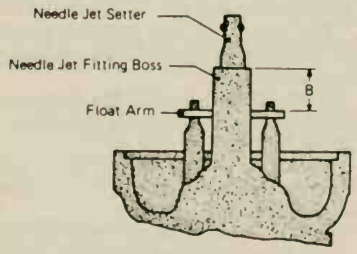
INDEPENDENT FLOAT TYPE

Method B

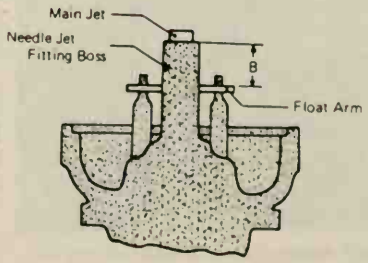


1. Remove the carburetor as described in the "Fuel Systems" section.
2. Remove the four phillips head float bowl screws, and carefully lift the carburetor body from the float bowl.
3. Turn the carburetor upside down, and measure the distance from the float arm to the top of the needle jet fitting boss.
4. Note that the float arm should be just touching the end of the float needle when the measurement is made.
5. Adjustment procedure is the same as for interconnected float height models. Refer to Steps 5 and 6 of "Interconnected Float Type."

Method C

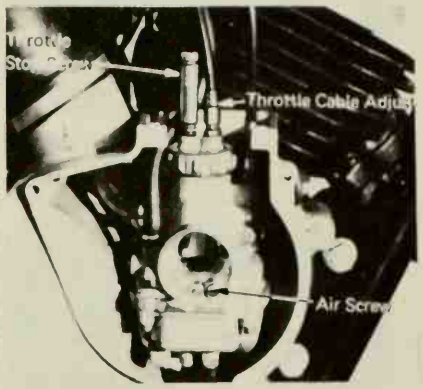


1. Remove the carburetor(s) as described in "Fuel Systems."
2. Remove the float bowl screws and take off the float bowl. Remove the gasket.
3. Turn the carburetor upside down. Hold the float arm so that the tang of the float arm is just touching the end of the float needle.
4. Measure the distance from the float bowl gasket surface (gasket removed) to the bottom edge of the float arm.
5. Compare the reading with the proper specification given in the chart at the end of this section. If adjustment is necessary, adjust the float tang as described in Steps 5 and 6 for "Interconnected Float Type," above.



Carburetor float height measurement, Method "C"

Bend the float tang to change float height



Carburetor float height for independent float models, Method "B"

Idle Speed and Mixture

NOTE: *These must be adjusted when the engine is at operating temperature.*

1. On all rotary valve, and the smaller piston-port models, the idle speed (or throttle stop) screw is located on the carburetor top. On other models, it is located on one side of the carburetor body.

Pilot air screw location (rotary valve models)

2. On most rotary valve models, the pilot air screw is located in the carburetor mouth, and is accessible after removing the carb cover plate (see illustration). On other models it is located on one side of the carburetor body.

SINGLES

1. Adjust the carburetor cable to the proper free-play. See "Maintenance."
2. Screw the pilot air screw in (carefully) until it bottoms lightly, then turn it out the number of turns shown in the "Tune-Up Specifications" chart.
3. Start the engine. When the engine reaches operating temperature, turn the pilot air screw in or out until the engine runs smoothly. It should not be necessary to vary the air screw more than ½ turn in either direction.
4. Adjust the throttle stop screw so that the engine idles at the desired rpm.

TWINS

1. Refer to the "Tune-Up Specifications" chart at the end of this section giving the pilot air screw settings, and turn each air screw in carefully until it bottoms lightly, then screw each out the proper number of turns.
2. Start the engine, and allow it to reach operating temperature. Remove

one of the spark plug leads, and turn the throttle stop screw on the carburetor of the running cylinder so that the engine will idle (as slowly as possible) on the one cylinder. Turn the pilot air screw for that cylinder in or out until the engine idles smoothly. It should not be necessary to vary the air screw setting more than ½ turn in either direction from the setting given in the chart.

3. Connect the spark plug lead for the disconnected cylinder, then remove the lead from the cylinder just adjusted. Repeat the above procedure for the second cylinder.

4. When both carburetors have been adjusted, run the engine with both plug wires connected. Idle speed will be high. Decrease idle speed by turning the throttle stop screws on each carburetor *equal* amounts until the desired idle speed is obtained.

5. Check cable adjustment and throttle slide synchronization. Refer to "Maintenance."

NOTE: *If satisfactory results cannot be obtained using the above methods, the carburetor(s) should be removed, cleaned, and inspected. Refer to "Fuel Systems."*

ENGINE AND TRANSMISSION

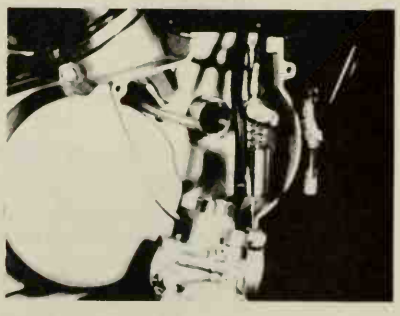
NOTE: *Engine component inspection techniques and procedures are outlined under "Engine Rebuilding" in the "General Information" section. Refer to the end of this section for specific Suzuki engine specifications.*

Operations Possible With Engine Installed

Component	Operation
Spark Plug(s)	Tighten, inspect, adjust gap, decarbon, replace, replace gasket.
Cylinder Head	Retighten, decarbon, check for warpage, repair, replace.
Cylinder Head Gasket	Inspect and replace.
Cylinder Barrel(s)	Remove carbon from ports, check for wear or scoring, repair, remove, rebore.
Piston(s)	Remove carbon from ring grooves, remove from engine, inspect for damage or wear, replace rings or pins, replace upper bearing.
Flywheel Magneto	Check and adjust contact gap and timing, check points for wear, check and replace magneto primary coil or lamp coils.
Alternator	Check and adjust contact gap and timing, check points for wear, check and replace condensers or points, check stator coils and rotor and replace if necessary.
Neutral Light Switch	Inspect for broken wire, inspect and replace switch or gasket.
Engine Drive Sprocket	Inspect for wear, replace.
Reed Valve	Inspect for cracks, replace.
Rotary Valve	Inspect for warpage, replace.
Starter Dynamo	Replace brushes, replace rotor.
Clutch Release Mechanism	Inspect, replace.
Primary Pinion	Inspect for backlash (wear), replace.
Clutch	Inspect plates for wear, inspect springs, inspect sleeve hub and housing, check backlash, replace.
Shift Shaft	Inspect return spring, replace.
Shift Pawls	Inspect pawl and spring, replace.
Oil Pump	Check cable adjustment, adjust, replace.

Operations Requiring Engine Removal

Component	Operation
Crankshaft	Inspect for wobble, replace, check bearings for wear, replace, check oil seals, replace, check con rod shake, replace.
Transmission	Check gears for breakage, check shafts for wear, replace gears or shafts, check bearings and replace.
Shifting System	Inspect shift drum grooves for wear or damage, replace drum, inspect shift forks for wear, replace.
Kickstarter	Inspect pinion for worn ratchet, replace, inspect pawl and spring, replace, inspect shaft return spring, replace.



ENGINE REMOVAL AND INSTALLATION

Removal

Clean the engine thoroughly before removal.

F-50

1. Remove the ignition switch ring and switch from the fairing by pushing it back behind.
2. Remove the fairing screws, disconnect the turn signal wires and remove the fairing.
3. Unscrew the knob that holds the left frame cover, then remove the cover.
4. Remove the battery holder, disconnect the battery wires and remove the battery.
5. Disconnect the magneto wires at their connector, then unsnap the oil tank strap and push the tank forward to disengage it. Remove the oil line clamp and line.
6. Unscrew the air cleaner nut and remove the air cleaner.
7. Remove the shift lever, engine sprocket cover, and left crankcase cover.
8. Separate the drive chain at the master link.
9. Unscrew and remove the oil pump cover plate and disengage the oil pump cable.
10. Disconnect the kickstart lever and the fuel and vacuum lines.

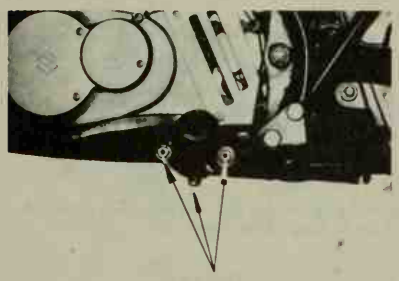
Carburetor removed from the case (rotary valve models)

11. Remove the right cover plate on the crankcase to expose the carburetor. Remove the rubber cap screws and slide the rubber cap up the cables it encloses, then loosen the carburetor clip bolt and remove the throttle slide and choke plunger caps from the carburetor. Swing the carburetor out of its recess and remove it.
12. Remove the exhaust system, drain the transmission oil and remove the engine mounting bolts to allow the engine to be lowered from the frame.

AC-50

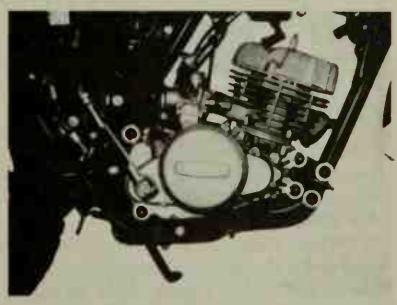
1. Turn off the fuel tap, disconnect the fuel line, disconnect the spark plug wire and remove the toolbox cover.
2. Remove the battery hold-down strap and battery.
3. Disconnect the magneto wires and remove the shift lever.
4. Remove the exhaust system.
5. Remove the engine sprocket cover and left crankcase cover.
6. Disconnect the drive chain at the master link.
7. Remove the oil pump cover plate and disconnect the cable.
8. Disconnect the oil line from the tank and drain the oil into a container.
9. Remove the right cover plate from the crankcase to expose the carburetor. Disconnect the carburetor as for the F-50 (Step 11, above).
10. Drain the transmission oil, remove the air cleaner and remove the engine mounting bolts. The engine now can be lowered from the frame.

TC-120



1. Turn off the fuel tap and remove the spark plug wire.
2. Remove the toolbox cover and disconnect the magneto wires.
3. Remove the shift lever and the reduction box cover. Disconnect the reduction linkage.
4. Remove the left crankcase cover.
5. Disconnect the drive chain at the master link.
6. Remove the carburetor covers and carburetor.
7. Remove the exhaust pipe.
8. Disconnect the oil line from the tank and drain the oil.
9. Remove the oil pump cover from the right crankcase half and disconnect the pump cable.
10. Disconnect the clutch cable at the hand lever and remove the skid plate on models so equipped.
11. Remove the engine mounting bolts and lower the engine.

TS/TC-90, TS/TC-100



1. Turn off the fuel tap and disconnect the fuel line.
2. Disconnect the spark plug wire and remove the oil tank cover, oil tank strap and oil line, draining the oil into a container.
3. Disconnect and remove the carburetor as for the F-50 (Step 11, above).
4. Remove the exhaust system.
5. Disconnect the magneto wires, remove the shift lever and remove the left crankcase cover.
6. Disconnect the drive chain at the master link.
7. Remove the oil pump cover plate and disconnect the cable.
8. Remove the air cleaner and the engine mounting bolts, then lower the engine from the frame.

TS/TC-125, TS/TC-185, TS-250, TS-400

1. Swing up the seat and disconnect the wires at the snap connector. Remove the exhaust pipe spring at the engine, the exhaust pipe mounting bolts, and remove the exhaust pipe from the machine.
2. Drain the transmission oil and dis-

Footpeg mounting nuts (TS-250)

Engine mounting bolt locations (125–185 cc)

connect the tachometer cable at the engine.

3. Remove the kickstarter lever from its shaft.

4. Remove the carburetor.

5. Disconnect the spark plug wire.

6. Remove the left rider's footpeg (TS-250R-A).

7. Remove the left sidecover. Disconnect the oil line and drain off the oil from the tank or plug the hole.

8. Disconnect the magneto wires. Remove the shift lever.

9. Remove the left crankcase cover. Disconnect the drive chain from the engine sprocket by removing the masterlink.

10. Remove the oil pump cover, and disconnect the cable from the pump.

11. Remove the skid plate.

12. Remove the engine mounting bolts, and remove the engine from the frame.

T-125

1. Turn off the fuel tap and remove the fuel lines and vacuum line.

2. Lift the seat, remove the tank bolt and disconnect the generator wires.

3. Remove the exhaust pipes and the battery.

4. Remove the shift lever and the left crankcase cover.

5. Disconnect the clutch cable at the hand lever.

6. Remove the drive chain and engine sprocket.

7. Disconnect the tach cable and oil pump cable.

8. Disconnect the oil line from the oil tank and drain the oil from the tank, or use a 6 mm bolt to plug the tank outlet.

9. Disconnect the plug wires and remove the throttle slides from the carburetors. Drain the transmission.

10. Disconnect the air cleaner hoses from the carburetors.

11. Remove the engine mounting bolts and lower the engine from the frame.

TWINS (EXCEPT T-125)

1. Disconnect the fuel lines at the petcock; remove the gas tank from the machine.

2. Disconnect the spark plug leads and remove the plugs. Drain the transmission oil.

3. Lift up the seat, remove the left and right side covers. Disconnect the battery cables, and disconnect the generator wires at the plastic coupling. Disconnect the starter wire at the starter relay (if equipped).

Disconnecting the alternator leads (GT-185)

4. Remove the front and rear footpegs.

5. Remove the exhaust system.

6. Disconnect the tachometer cable, the clutch cable, and the oil pump cable (all at the engine).

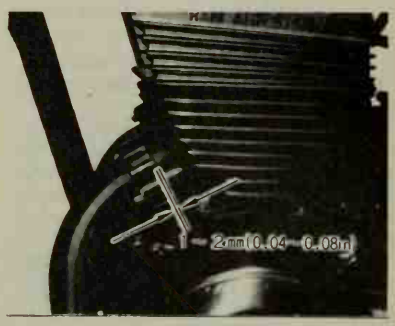
7. Unscrew the carburetor caps and pull out the throttle slide assemblies. Remove the air cleaner.

8. Disconnect the oil pump line at the CCI tank, and either drain the tank or plug the outlet.

NOTE: *On some models, the rubber tire valve cap can be used to plug the tank.*

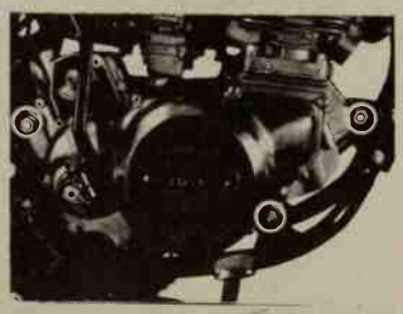
9. Remove the gearshift lever. Remove the engine sprocket cover.

10. Disconnect the drive chain and disengage it from the engine sprocket.



11. Remove the engine mounting bolts, take out the mounting plates where fitted, and remove the engine from the right-side of the frame.

NOTE: *When removing the engine, do not use the gearshift shaft as a hand hold.*



Installation

1. Installation is the reverse of the removal procedure. Be sure that the engine mounting bolts are tightened evenly and securely before beginning the operation. Refer to the "Engine Torque Specifications" chart at the end of this section.

2. On late models, the exhaust pipe clamps are threaded onto the exhaust pipe, and are secured to the cylinders with nuts. Proper clearance between the clamp and the cylinder must be maintained (1–2 mm/0.04–0.08 in.), and the adjustment can be made by turning the clamp.

The gap between the cylinder and the clamp must be correct

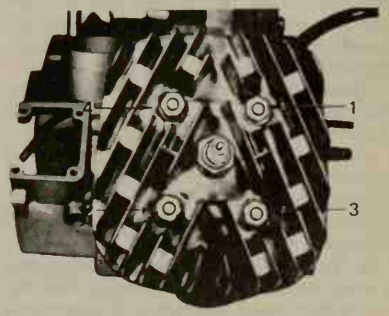
Removal

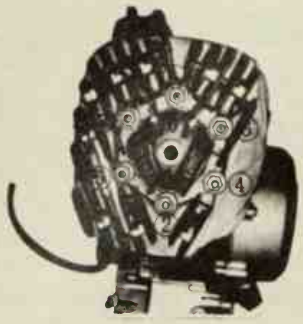
SINGLE-CYLINDER MODELS

1. If the engine is still in the frame, remove the spark plug. Remove the exhaust system.



2. Remove the gas tank if more access to the cylinder head nuts is needed, as on machines over 250 cc.

3. On piston-port models, remove the carburetor after disconnecting the air cleaner.



4. Loosen each cylinder head nut in a cross pattern ¼ turn at a time until they are loose, then remove the lockwashers. Lift the cylinder head up until it is clear of the studs, and remove it from the machine. Remove the head gasket.

NOTE: *If the head is stuck to the cylinder, t p around it with a plastic mallet til free.*

5. O ne models, the head is secured l ough-studs anchored in the cranke hile others have separate nuts the cylinder to the cases.

Loosen and tighten the cylinder head nuts in a cross pattern

Head nut loosening and tightening order (6-bolt head)

Head nut tightening and loosening sequence for twins with a one-piece head

If the latter is true, loosen gradually, then remove the cylinder base nuts and lockwashers.

6. On all models, position the piston at Top Dead Center, and lift up the cylinder. When the cylinder spigot is clear of the crankcase, stuff a clean rag between the cylinder and the crankcase, draping it over the crankcase studs, if any.

7. Continue lifting the cylinder straight up from the crankcase until the piston comes out. Then remove the cylinder from the machine.

8. Keep the rag in place. With a thin screwdriver or needlenose pliers, remove the piston circlips. Note that new ones should be used upon reassembly.

9. Grasping the piston with one hand, use a suitable sized soft drift to push the wrist pin out of the piston until the piston can be removed from the connecting rod.

CAUTION: *If the wrist pin cannot be removed in this manner, never attempt to drive it out by striking it with any sort of instrument. With a propane torch, gently heat the piston crown (and only the crown, not the skirts), and then push out the wrist pin as directed above. In both cases, exert steady pressure on the wrist pin, rather than a series of impacts.*

10. Remove the piston from the machine. If desired, remove the con rod needle bearing. Take off the cylinder base gasket.

TWIN-CYLINDER MODELS

Various top end setups are used, although most models use separate cylinder heads, and all use separate cylinders. The GT-185 and GT-250A cylinder head is a one-piece casting.

Cylinders and cylinder heads may be secured either by through-studs, or by studs in the cylinder (which secure the head) and studs in the crankcase (which secure the cylinder).

Removal procedures are the same as for single-cylinder models described above. Note the following points:

1. On the GT-185, remove the metal shield around the spark plugs before removing them.

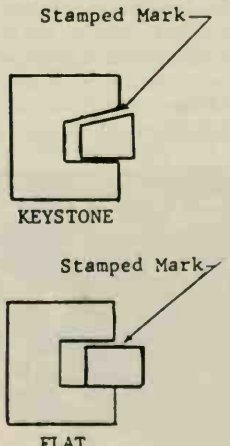
2. On the GT-250K-M, unscrew and remove the Ram-Air covers.

3. Proper cylinder head nut loosening procedure is critical, especially with the one-piece head. Loosen the nuts in a cross pattern, ¼ turn at a time until they are loose.

4. Mark the position of each piston (i.e. RH, LH) *before* removing it from its connecting rod. The piston *must* be correctly installed in its cylinder, and with its own wrist pin.

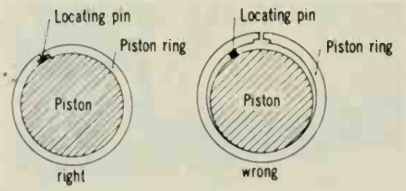
Inspection

ALL MODELS



1. Refer to the "Piston Clearance Specifications" chart at the end of this section for ring end-gap and piston clearance specs.

2. When fitting rings, note the following:



a. Some late model machines (i.e. TS-250A) have a SCEM-plated cylinder which uses special rings. Rings from earlier models cannot be used with these cylinders. SCEM-plated cylinders are marked "E" on the left side near the mounting flange. Rings for SCEM cylinders are marked with a "C" (i.e. "TC," "RC").

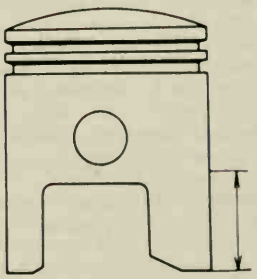
b. Most late models used tapered (keystone-type) rings at top and bottom, although on some, only the top ring is tapered. If tapered *and* flat rings are found on a piston, the tapered ring is always installed in the top groove.

c. Install rings which are tapered with the tapered side *up*. Standard as well as tapered rings are stamped "T", "R", or "NR" on one side with a "C" for SCEM cylinders. The ring is always installed so that the stamp mark faces *up*. If an expander is fitted beneath the lower ring, do not forget to install it.

Two types of piston rings are used. Install with the stamped mark up

Ensure that the ring ends are located on either side of the locating pin as shown

Keystone ring showing 7° taper of upper surface

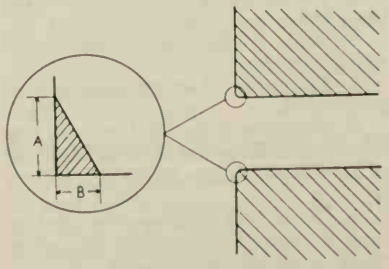


d. When the rings are installed, be positive that the ring ends are located on either side of the locating pin in the groove (see illustration).

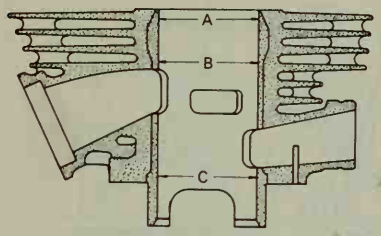
3. When installing new rings, the cylinder walls should be cleaned up with a hone or with #400 emery cloth. Remove burrs or sharp edges from ports.

This applies to SCEM cylinders as well.

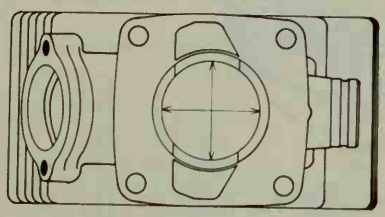
4. On standard (non-SCEM) cylinders, maximum allowable taper or out-of-round is 0.05 mm (0.002 in.).



5. Piston clearance is obtained by measuring the piston diameter 90° from the wrist pin holes at the specified distance above the edge of the skirt. The measurement point is different for various models. Refer to the "Piston Clearance Specifications" chart at the end of this section.



The piston diameter must be measured at the correct distance above the skirt for each model

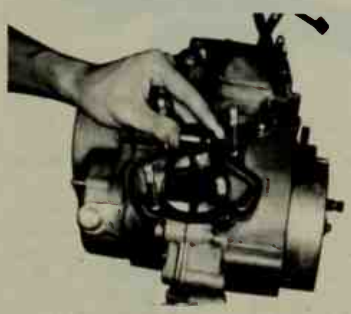


Compare the piston diameter with the smallest of the cylinder bore measurements and compare to the serviceable limits given.

If boring is necessary, cut cylinder(s) to the clearance given. Pistons for most

Chamfer the ports after the cylinder is bored. "A" should be approximately 1-1.5 mm; "B" about 0.3-0.5 mm

Measure the bore in two directions at Points "A", "B", and "C"



models are available in 0.5 and 1.0 mm oversizes. Rings for these pistons are stamped "50" and "100" in addition to the usual marks.

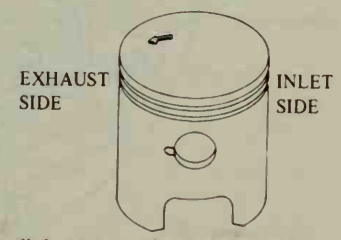
Be sure that the port edges are chamfered after boring. Hone the cylinder(s) after boring.

5. SCEM-plated cylinders should be checked for flaking or wear. These cylinders are marked "E" on the left side above the mounting flange. If a flaked area exceeds 2 sq. mm in area, the cylinder should be replaced. These cylinders should be measured for wear at a point about 20 mm (0.8 in.) from the top of the bore. Max. allowable wear is 0.035 mm (0.0014 in.) which in the case of the TS-250A would be 70.040 mm (2.7575 in.).

SCEM-plated cylinders cannot be bored, and must be replaced in the event of wear or damage. In most cases, the piston will have to be replaced as well.

These cylinders may be lightly honed as when fitting new rings to aid break-in.

Removing the rod small end needle bearing



6. When a new or unworn wrist pin is fitted, check the vertical play in the wrist pin. Maximum play should be 0.045 mm (0.002 in.). If it is in excess of this, the needle bearing should be replaced.

NOTE: *If the cylinder is being rebored, or if the second set of replacement rings is being installed, the needle bearing should be replaced as well, as a preventive maintenance measure.*

Installation

ALL MODELS

1. Fit new cylinder base gasket(s).
2. Install the con rod small end needle bearing, coating it liberally with clean CCI oil.
3. Install the piston on the connecting rod.

Install the piston so that the arrow on the crown points toward the exhaust port

CAUTION: *Install pistons so that the arrow stamped on the piston crown points toward the exhaust port. If no arrow is fitted, install the piston so that the notch in the piston wrist pin hole faces the rear of the engine.*

On twins, be sure that each piston is fitted on the proper connecting rod.

4. Use new wrist pin circlips. Be sure that the circlips are firmly seated in the grooves. Locate the rings so that the ends flank the locating pins in the grooves.

5. Lubricate the rings and skirt with clean CCI oil. Position the cylinder above the piston, and insert the piston into the bore, compressing the rings with your fingers as you do so. Continue moving the cylinder down onto the crankcase until it is seated. If cylinder base nuts are fitted, thread them onto the studs and tighten them in a cross pattern.

6. Install new head gasket(s).

NOTE: *If the gasket has projecting marks on one side, install that side facing UP.*

7. Fit the head(s). Install the head nut washers and the nuts. Head nuts should be torqued as shown below in a cross pattern and in increments of 2–3 ft lbs.

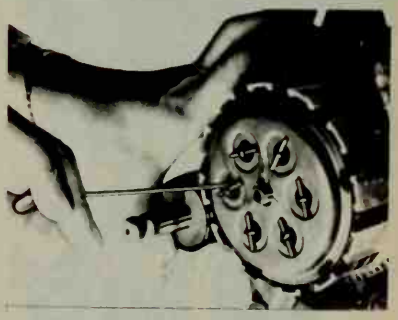
Model	*Cylinder Head Torque (ft lbs)*
Singles	
Four-bolt head	15–18
Six-bolt head	11–15
Twins	
T-125	11
(G) T-500	
8 mm	14
10 mm	25
All other	15–18

NOTE: *The head nuts should be tightened in the same cross pattern as on removal. Refer to the illustrations at the beginning of this section.*

LOWER END AND TRANSMISSION

The following section covers removal, service, and installation procedures for the clutch, crankshaft, and transmission.

The clutch is easily accessible after removing the right crankcase cover. The crankcases must be split to get to the crank assembly and the transmission gear clusters.



Clutch (All Models)

REMOVAL

Removing the clutch on all models, except the F-50, requires the use of a special tool to hold the clutch hub while the nut is loosened. In addition, a replacement gasket for the right crankcase cover should be on hand

NOTE: *If the shop tool for holding the clutch hub is not available, a substitute can be fabricated by welding a hefty handle onto an unused clutch steel plate. Alternatively, if the engine is still in the frame, engaging First gear and applying the rear brake should enable the nut to be removed.*

1. Remove the pinch-bolt and carefully pull the kickstarter lever off the splined shaft if it is fitted to the right-side of the engine.
2. Drain off the transmission oil.
3. On rotary valve models, remove the carburetor.
4. On rotary valve models, loosen the air cleaner hose clamp, and disconnect the hose from the engine case. Unscrew and remove the oil line banjo bolt in the carburetor compartment if fitted.
5. Place something beneath the case to catch any residual oil which will leak out when the cover is pulled off.
6. Remove the screws and pull off the right sidecover. Remove the gasket.

Removing the clutch pins

7. The clutch is now exposed for service. Disassembly procedure depends on the type fitted.

a. On the F-50, bend down the lock-tab on the clutch nut, and, using the special tool to hold the hub steady, remove the nut. Then use a thin screwdriver to remove the large spring clip which holds the plates in. Remove the plates, keeping them in the proper order. Pull off the clutch hub.

b. If the clutch pressure plate is secured with crosspins as on most singles and smaller twins, use a hook made from a small diameter welding rod or a stout piece of steel rod, and use it to pull up on the clutch springs. While doing this, remove the crosspins with a needlenose pliers. Remove all of the clutch spring crosspins.

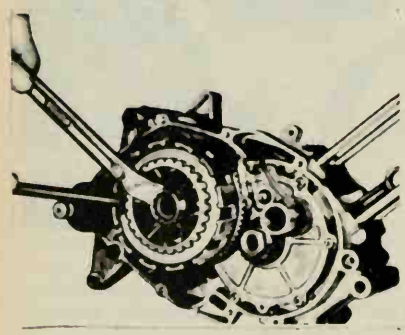
c. If the clutch pressure plate is

rack-and-pinion clutches and the larger twins, unscrew each bolt a couple of turns at a time in a cross pattern until they can be removed. Remove the washers and clutch springs as well.

8. On all models (except the F-50), once the spring bolts or crosspins are removed, take off the clutch pressure plate.

9. Take the steel and friction plates out.

CAUTION: *Note the location of each type of plate and keep them in order when removed.*



10. Remove the clutch release rod which is fitted through the center of the clutch shaft.

11. Bend down the lockwasher on the clutch hub nut with a hammer and chisel.

12. Using one of the methods outlined above (see the Note, above), remove the clutch hub nut. Pull the clutch hub off the shaft, noting the presence of any thrust washers between the hub and housing. Remove the clutch housing. Remove the spring fitted behind the housing.

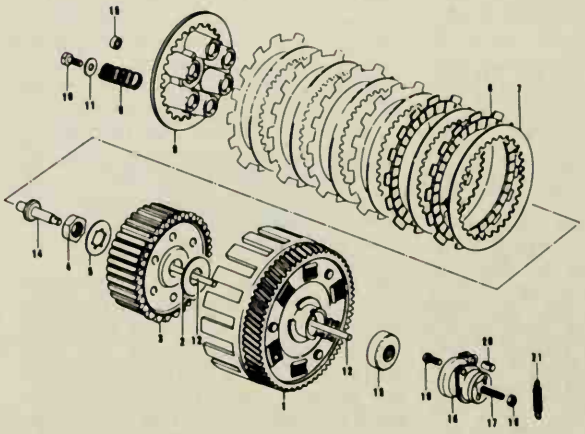
INSPECTION



1. Max allowable steel plate warpage is 0.1 mm (0.004 in.). For friction plates, it is 0.4 mm (0.016 in.).

2. Check clutch spring free length. Specifications for most models are given in the "Clutch Specifications" chart at the end of this section. Where not given, replace the springs as a set if any of them is compressed 1.5 mm (0.06 in.) or more when compared to the other springs in the set.

3. Check friction plate condition and wear and compare to the specifications.

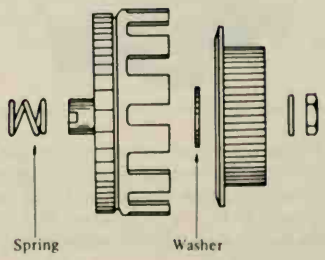
4. Gear backlash between the primary gear and the clutch housing gear can be checked with a suitably mounted dial gauge. This can be arranged to measure the movement of the clutch housing gear with the primary gear locked in place. The resultant movement gives an indication of the wear which has taken place on the teeth.

An alternative method is to use a thin, soft piece of solder. Trap this between the teeth where the two gears mesh and turn it through. Measuring the thickness of the solder will provide the backlash value. Average backlash is 0.0006–0.0027 in. If backlash exceeds 0.006 in., both the primary drive and the clutch gear should be replaced.

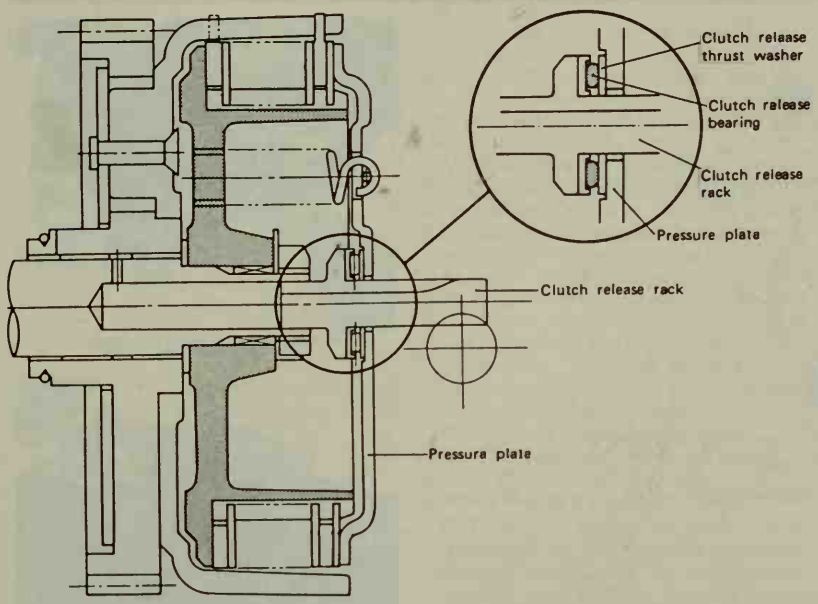
INSTALLATION

Although installation is simply the reverse of the removal procedure, note the following points:



1. If crosspins are used to secure the clutch springs, check the installation of the springs in the clutch hub. The spring bottoms must not protrude through the inner side of the hub. Check with the edge of a steel rule to ensure that the spring ends are flush with the surface of the hub.

2. Before installing the hub on the clutch shaft, ensure that the thrust washer is fitted between the hub and housing.



3. There are marks on the edge of the clutch pressure plate and edge of the

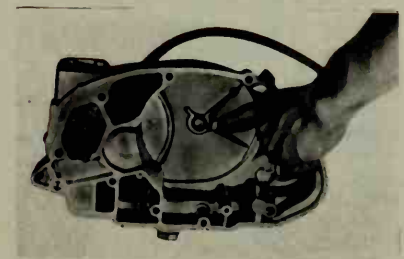
Clutch thrust spring and washer positions

Clutch release bearing installation (TS-125A)

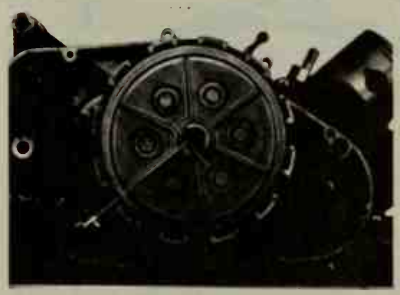
Align the marks on the pressure plate and the hub when installing the pressure plate



clutch hub. When the pressure plate is fitted, these marks *must* align.

4. If the pressure plate is secured with bolts or springs, tighten these evenly and in a cross pattern.

5. Check the condition of any oil seals in the right crankcase cover. There will be one for the kickstarter shaft, and some models have a countershaft oil seal fitted into the cover. Replace if the lips are torn. Apply some oil to the lips of any seals before refitting.



6. Always use a new crankcase cover gasket. A gasket sealer (non-hardening) can be used if desired, but apply it sparingly to keep it off the internals.

7. Tighten the cover screws with an impact driver.

The O-ring in the case must be in good condition

8. On the rack-and-pinion clutches, be sure that the clutch release rack is aligned to mesh properly with the release pinion before fitting the sidecover. Hold the release lever in position when installing the cover.

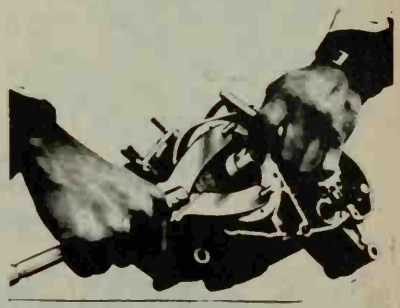
On the TS-400, line up the release rack as shown before refitting the cover

Splitting the Crankcases

SINGLES

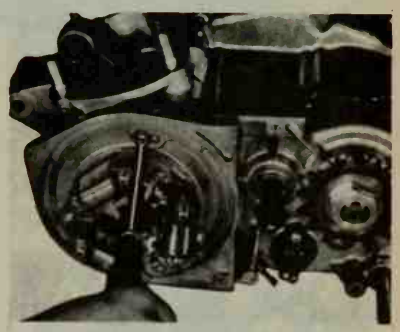
The crankcases are split vertically. Splitting the cases is necessary to service the crankshaft, connecting rod, gear clusters, and, on most models, the kickstarter gear.

It is necessary to remove the engine from the frame, and to remove all of the assemblies beneath the left and right crankcase covers.



Before beginning, have on hand a complete set of engine gaskets, rotary valve O-rings (if applicable), and new crankshaft and transmission shaft oil seals.

In addition to a torque wrench, impact driver, and plastic mallet, a special puller for the flywheel magneto and a jig to split the cases will be needed. On some models, a special tool to mate the cases is also required.



Disassembly

Refer to the appropriate sections for removal procedures.

1. Remove the engine from the frame.
2. Remove the cylinder head and barrel.
3. Remove the carburetor on rotary valve models.
4. Remove the left-side crankcase cover(s).
5. With the special holder to secure the magneto flywheel, remove the flywheel nut.
6. Holding the flywheel in place, use the special puller to remove it from the crankshaft. Remove the woodruff key from the crankshaft.
7. Unscrew and remove the magneto stator.
8. Bend down the lockwasher tab if necessary, loosen the nut, and take off the engine sprocket.

9. Remove the neutral indicator switch if fitted.
10. Remove the oil pump.

CAUTION: *Refer to the "Lubrication System" section for proper removal and installation procedures for the oil pump.*

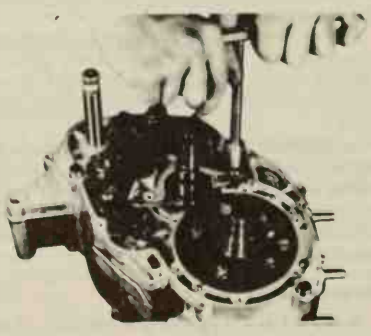
13. Remove the right-side crankcase cover. Remove the clutch assembly. Bend down the locktab, and remove the primary gear nut. Pull the gear off the crankshaft, and remove the woodruff key.

14. Remove the gearshift shaft mechanism.

Gearshift mechanisms are of two types: pawl or sector gear. The two are easily distinguished by reference to the accompanying illustrations.

Pawl-type:



a. Remove the circlip fitted to the left-side of the gearshift shaft.

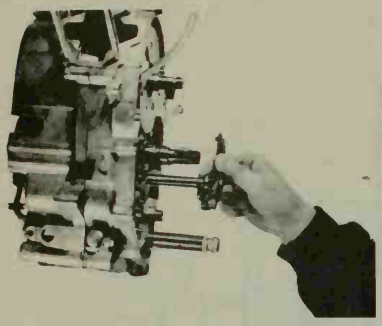
b. Loosen the shift drum stopper bolt.

c. Remove the phillips head screw which secures the shifter pins on the shift drum, and take off the retainer plate.

NOTE: *If the pins are removed from the shift drum, carefully note their position. Some models use one stepped pin or a short pin, and this must be reinstalled in the proper location.*

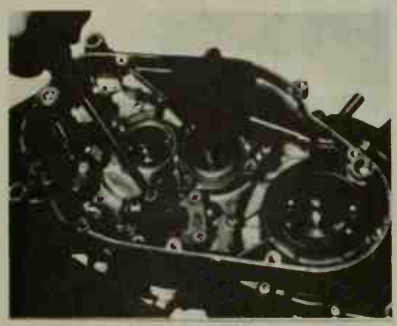
d. Remove the drum stopper after disconnecting its spring. Remove the shift drum guide. On most models this is secured with a circlip. Remove the circlip if fitted. On other models, bend down the locking tabs on the guide lockplate, and remove the guide lockbolts prior to removing the guide.

Loosening the shift drum stopper bolt



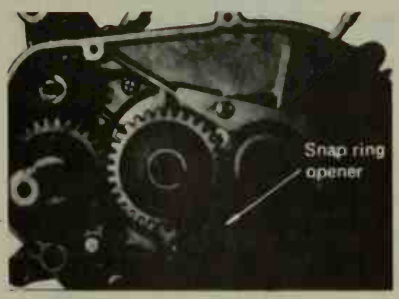
e. Pull the shifter shaft and pawl out of the case.

Sector gear-type:



a. This type of shifter can be pulled out of the case after removing the clutch.

The corresponding gear mounted on the shift drum should be left in place until the cases are split.



b. Remove the shift pawl lifter and the pawl stopper after removing their securing screws.

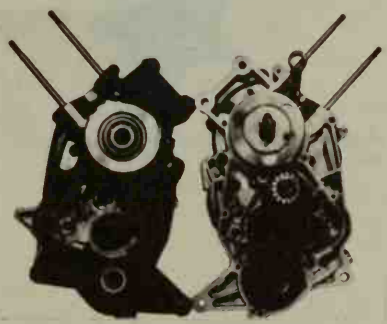
Removing the rotary valve seat

15. Where applicable, remove the circlip which secures the kickstarter idler gear and remove the idler gear, then the drive gear. On models not so equipped, remove the kickstarter spring guide, and the kickstarter spring.

16. On rotary valve models, remove the screws which secure the rotary valve seat. Take off the valve, the valve guide, then take off the valve guide positioning piece with a needlenose plier.

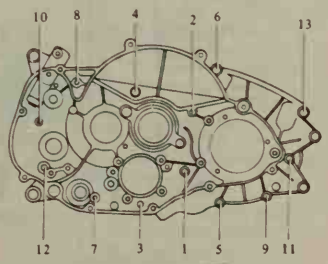
17. If it is fitted, remove the rubber plug on the top of the crankcase behind the cylinder. Use a socket extension as shown to remove the banjo bolt.

18. Remove the shift drum stopper plug, spring and plunger. This is usually at the underside of the cases.



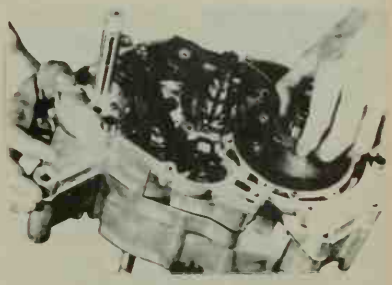
19. Remove the crankcase screws.

20 The cases can now be separated. A special jig is recommended, as illustrated, although a substitute can be used.



CAUTION: *Tapping the ends of the crankshaft or transmission shafts to separate the cases is not recommended, and is likely to warp them. Equal pressure should be applied to the end of the crank and to one of the transmission shafts. The cases can be heated gently in the vicinity of one of the crank bearings to facilitate disassembly.*

21. If the cases have been properly separated, all of the interior components will remain in place in one of the crankcase halves. They are best left this way until the type of service needed is decided upon, if possible.



22. The crankshaft and the transmission shaft can be removed from the case half by gently heating the case with a propane torch in the vicinity of the bearing, and then very lightly tapping the crank or transmission shaft out with a plastic mallet.

Inspection

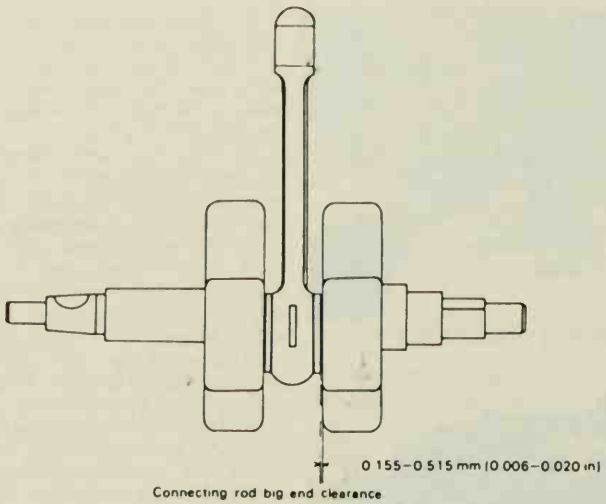
CRANKSHAFT

1. After removing the crankshaft from the case, check the connecting rod big end bearing. Slowly rotate the rod around the crankpin. Rotation should be smooth and effortless. If the rotation is noisy, or tends to bind, the big end bearing must be replaced.

2. Check the side-play of the connecting rod. Measured at the small end of the rod with a dial gauge, maximum

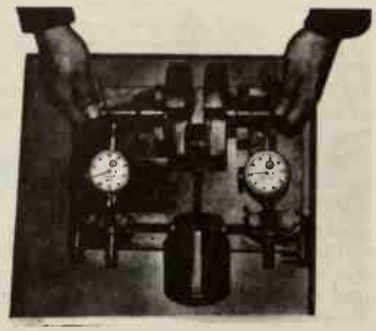
Connecting rod small end shake indicates the condition of the big end bearing

movement should be about 3 mm (0.118 in.). Play greater than this amount indicates a worn big end bearing.



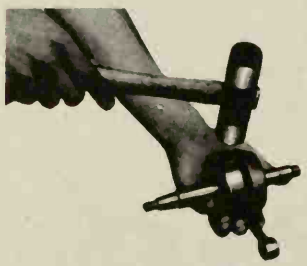
3. On the TS-400, clearance between the rod big end and the crankshaft flywheel should be 0.155–0.515 mm (0.006–0.020 in.), and is measured with a feeler gauge.

4. Since the crankshaft is a pressed together unit, replacement of the rod big end bearing necessitates disassembling the crankshaft with a press.



5. The crankshaft run-out should be checked by mounting the assembly on a suitable jig such as a set of V-blocks and measuring run-out with a pair of dial gauges as shown. Run-out should not exceed 0.06 mm (0.0024 in.). If run-out is not excessive, it can be brought to within tolerance by realigning the flywheels.

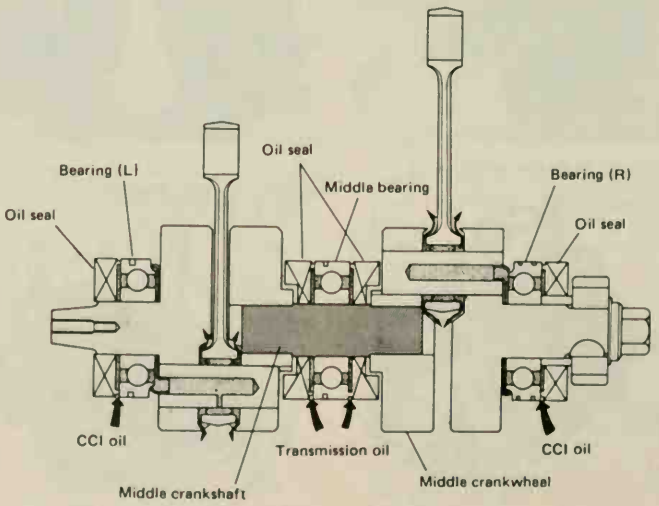
NOTE: *For crank alignment, a brass hammer is used. Do not use a steel one.*



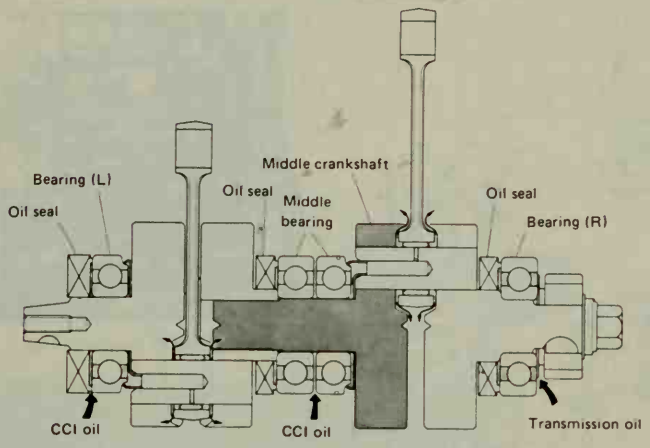
6. The crankshaft must be checked for eccentricity and for parallel flywheels. The crankshaft flywheels are eccentric if one has been rotated slightly ahead of the other. The flywheels are nonparallel if they lean toward or away from each other.

Measure rod side clearance between the rod big end and the flywheel on the TS-400

Measuring crankshaft run-out with dial indicators

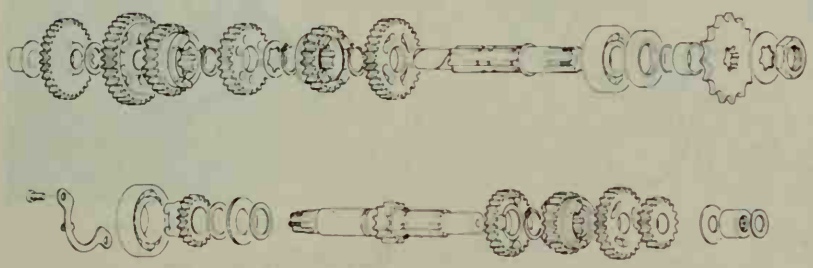


Aligning the crankshaft flywheel with a brass hammer



7. Turn the crank in the jig. If the dial gauges do not move the same distance, and do not begin and end their movement at the same time, the crankshaft flywheels are both eccentric and nonparallel. In this event, eccentricity must be taken care of first.

8. To correct eccentricity, rotate the crank until the drive-side dial gauge indicates the high point of its travel. Stop at this point. Imagine a line drawn from one of the dial gauge shafts to the other. Mark the spot on the drive-side flywheel at the spot this line would cross it. Remove the crankshaft from the aligning jig, and, with the brass hammer, strike this spot on the drive-side flywheel smartly. Be sure that you are holding the crank assembly by the magneto-side shaft while doing this. Recheck alignment, and repeat this procedure as long as necessary until the dial gauge needles begin and end their travel at the same time.



9. Replace the crankshaft assembly in the jig, and rotate it until the needles reach their highest point of travel. If the crankpin lies along an imaginary line drawn between the ends of the two dial gauge shafts, the flywheels are evidently pinched together opposite the crankpin.

To correct this condition, insert a wedge, preferably of wood or soft metal, between the flywheels at a point opposite the crankpin, and, supporting the crank in one hand, strike the wedge with a hammer to spread the flywheels apart. Continue until the flywheels are parallel within specifications.

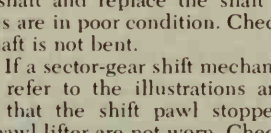
10. If, when checking for parallelism, the crankpin was *not* along or near the line drawn between the ends of the dial gauge shafts, if it was opposite this line, then the flywheels are too far apart, opposite the crankpin. In this case, once again make a mark on either flywheel where the imaginary line would cross it. (Note that the crank should be positioned so that the dial gauges are at the highest point of their travel). Remove the crank, and, with the brass hammer, strike the flywheel sharply on the *side* to bring the flywheels closer together. Check again, and repeat the procedure until crank run-out is within specification.

11. Clean the crank assembly thoroughly, and oil the big end bearing well.

NOTE: *Excessive run-out is sometimes caused by a loose crankpin or by forcing the crank in or out of the cases.*

TRANSMISSION

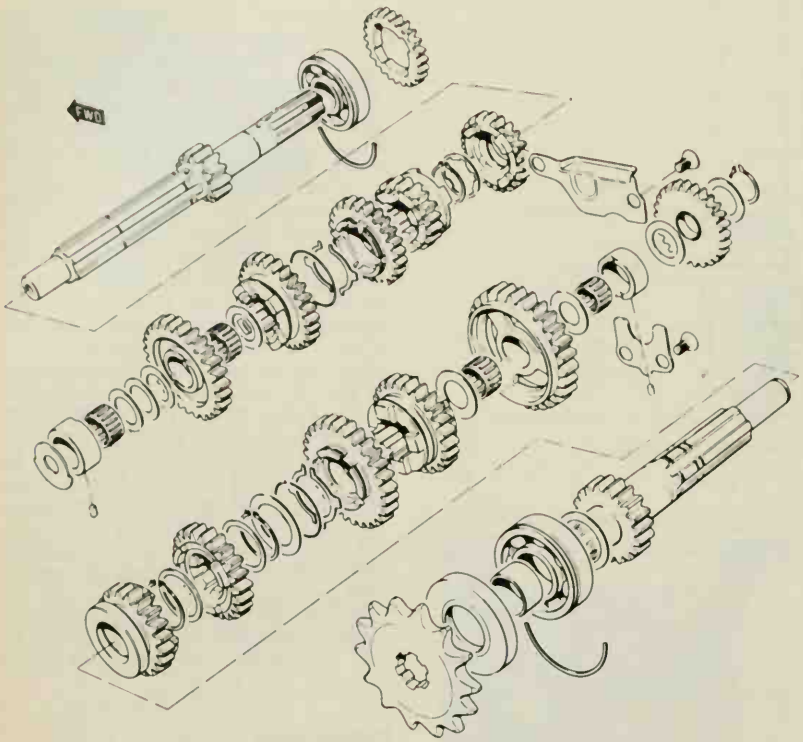
Transmission components should be checked in place in the crankcase half whenever possible. If removing the transmission is necessary, be sure to note the location of all thrust washers, circlips, and gear positions before disassembly.



GEARSHIFT ASSEMBLY

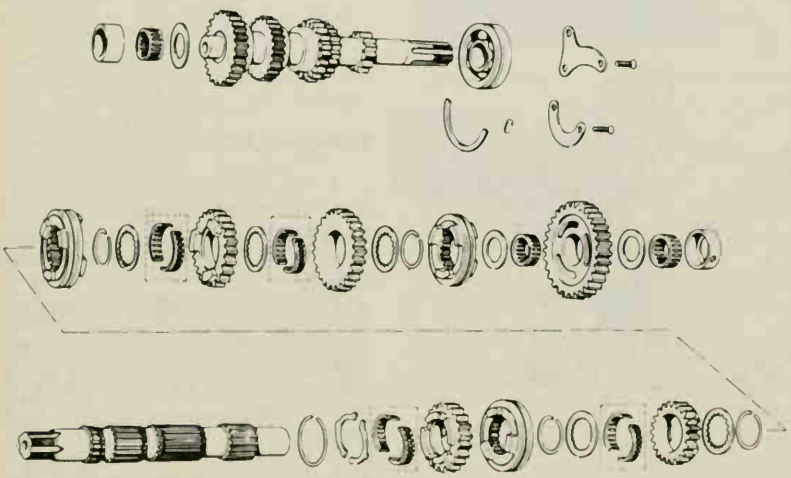
1. On all models, gear changing is accomplished by the rotation (in both directions) of the shift drum. The motion of the drum moves the shift forks which engage and disengage the various gears.

2. On models which use a pawl-type shift mechanism, the shift forks are fitted directly on the shift drum. On models with the sector gear-type shifter, the forks are mounted on spindles, with pins on the forks engaging grooves in the shift drum.



3. Check the splined end of the gearshift shaft and replace the shaft if the splines are in poor condition. Check that the shaft is not bent.

4. If a sector-gear shift mechanism is used, refer to the illustrations and inspect that the shift pawl stopper and shift pawl lifter are not worn. Check that the shift pawls and springs are not damaged.



Inspect the shift pawl stopper for wear at the points shown

5. If a pawl-type shift mechanism is used, check the condition of the shift drum pins with which the pawl engages. Inspect the pawl itself and replace it if

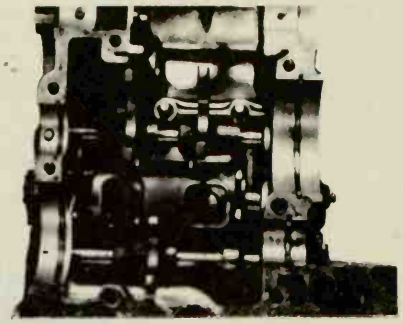
bent or if it shows wear on the fingers or stop.



6. Check the condition of the shift shaft return spring. Note the illustration showing the correct positioning of the spring prior to installation.

7. On pawl-type shift assemblies, the shift forks can be removed from the shift drum after the cotter pin is removed.

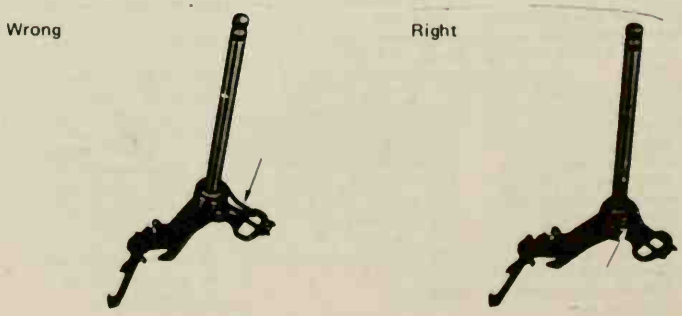
CAUTION: *Note the position of the shift forks carefully before removing them. Mark them for position. In most cases, they are not interchangeable.*

8. Inspect the grooves in the shift drum for wear. The drum must be replaced if the grooves are not perfect.

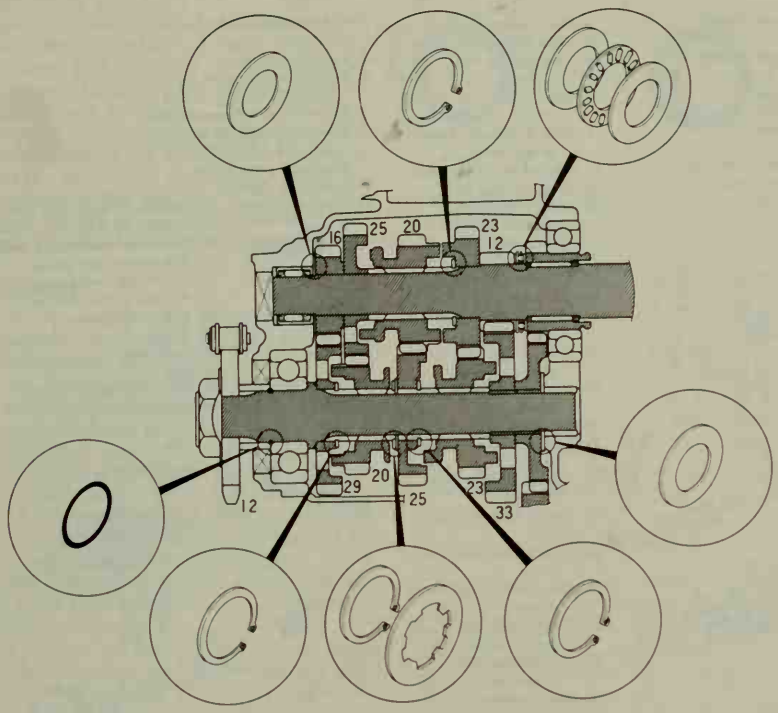
9. Inspect the shift forks. If the fingers are worn looking or bent, the forks should be replaced.

10. If fork shafts are used, roll them on a flat surface to ensure that they are not bent. If they are, they must be replaced.



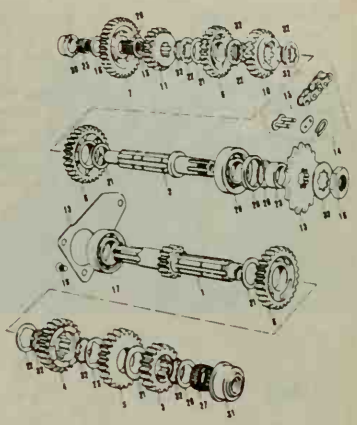
KICKSTARTER ASSEMBLY

1. The kickstarter gears should be checked for worn, chipped or broken teeth, and replaced if damaged.



2. Inspect the kickstarter shaft, especially for worn or damaged splines.

3. The kickstarter shaft pawl must be free of wear, or it should be replaced.



4. If a ratchet wheel is fitted, the dogs and stopper on the wheel must be free of chips or other signs of wear.

Installation of the gearshift return spring must be correct

Check the inner race for back-and-forth movement. None should be possible. If the inner race can be moved back-and-forth, replace the bearing.

NOTE: *Crankshaft bearings should be replaced as a set, since, if one is worn, the other has probably been subjected to some stress.*

6. Where transmission shaft bushings are fitted (right-side of the countershaft), these should be inspected for scoring or wear, and replaced if necessary. They can be removed and installed after heating the case as with the bearings. When installing the bushings, ensure that they are correctly installed. Refer to the illustration under "Assembly," which follows.

OIL SEALS

Oil seals are fitted on the outside of the bearings in the left crankcase, and one is fitted on the inside of the right-

retainer (if fitted). The case should be heated gently around the bearing with a propane torch, and the bearing lightly tapped out of the case.

2. Clean the bearings thoroughly in clean oil. Check for general condition first.

3. Check the bearings by rotating them slowly. Rotation must be smooth and noiseless. If the bearing rotation is rough or noisy, or if binding is felt, the bearing must be replaced.

4. If the balls or rollers are visible, check them for any worn or flat spots.

5. Place bearings on a smooth surface, holding the outer race firmly in place.

Pry out oil seals with a hooked instrument as shown

side crankshaft bearing. Oil seals, especially the crankshaft oil seals, should be replaced as a matter of preventive maintenance. Remove the seals with a hooked tool as shown. This will allow the seals to be pried out of the case without damage to the seal lips in the event that the seals must be reused. Check the condition of the seal lips. If there is any doubt at all as to their condition, the seals should always be replaced.

Assembly

1. Assembly is the reverse of the disassembly procedure. The following points should be noted:

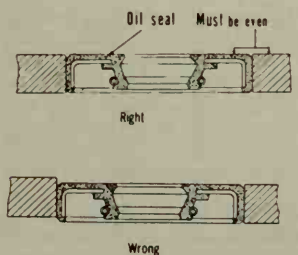
2. Bearings should be installed with a suitably sized drift as shown, after the cases have been heated.

Lubricate all of the interior crankcase components, especially the bearings, before reassembly.

3. Oil seals should also be installed with a drift. Seals should be flush with the case surface after installation. Refer to the illustration. Grease the lips of the oil seals thoroughly before inserting any shafts into them.

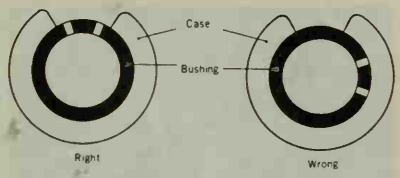
The lips of the oil seals must bear properly against the shafts inserted into them as illustrated. If they do not, work the shaft back-and-forth until the lips are correct.

4. Note the correct installation of transmission shaft bushings shown in the illustration.

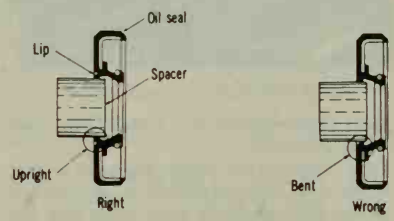


5. Be sure that all the thrust washers are correctly positioned on the transmission and kickstarter shafts.

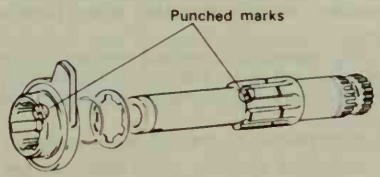
6. Where applicable, ensure that the punch mark on the kickstarter shaft aligns with the mark on the ratchet wheel.



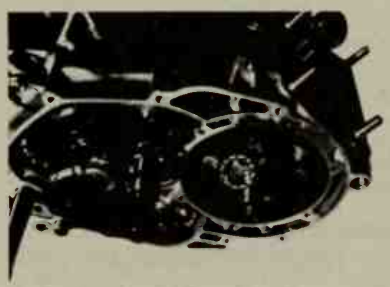
7. On rotary valve models, the timing mark on the valve must face outward, and must align with the valve guide pin in the crankshaft.



Bearings and seals should be installed by drifting them straight into the cases



The oil seal outer surface must be flush with the case surface after installation



The transmission shaft bushing must be installed in the case as shown

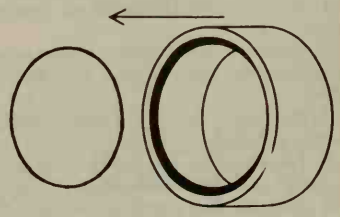
The shifter pawl should be installed so that the thickest side (A) faces outward



8. Carefully replace all of the O-rings in the rotary valve assembly, and ensure that they are properly seated.

9. When installing the gearshift mechanism, if pawl-type, be sure that the shift drum pins are installed in their proper holes and that the pin retainer is installed correctly. If sector gear-type, first ensure that the shift drum pawls are properly located (thick side out), and next that the gears align as shown in the illustration. Note that the five-toothed side of the shift drum gear faces the shaft sector gear.

On sector gear shifters, install the shift shaft, lining up the gears as shown

10. On all models, the gearshift shaft return spring must be installed as shown in the illustration earlier in this section.

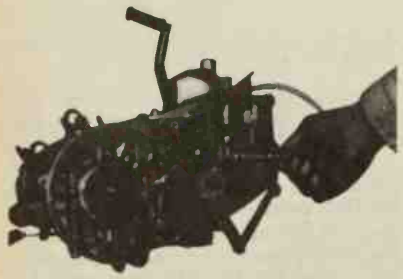
The engine sprocket spacer chamfered edge is fitted with an O-ring on the TS-400

11. Use a new gasket, and some gasket sealer when assembling the cases. A special tool is used to correctly mate the case halves.

12. Be sure to tighten the crankcase screws in a cross pattern. Be sure that they are secured properly. Use an impact driver.

13. Before installing all of the left and right crankcase components, check that crankshaft rotation is proper, and that the gears mesh properly.

TWINS



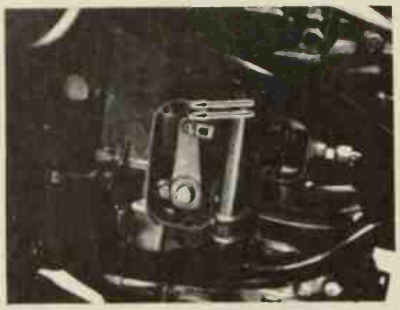
The cases are split horizontally. The engine must be removed from the frame. The only special tool required is that necessary to remove the alternator or dynamo from the crankshaft.

Have on hand: a complete engine gasket set, new crank and transmission shaft oil seals, a torque wrench and an impact driver.

Disassembly

Refer to the appropriate section for disassembly procedures.

1. Remove the engine from the frame.
2. Remove the cylinder heads, barrels, and pistons.



Removing the gearshift linkage (GT-185)

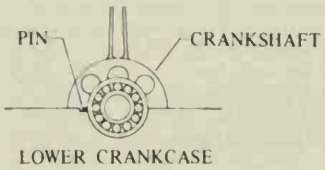
Removing the armature with the special puller

3. Remove the left and right crankcase covers.
4. Remove the alternator or dynamo stators.
5. Remove the dynamo armature or the alternator rotor using the special puller.
6. Remove the gearshift linkage where applicable.
7. Remove the oil pump cover, the oil pump, and the kickstarter.
8. Remove the clutch assembly. Remove the kickstarter return spring, gearshift assembly in the right crankcase. Pull out the gearshift shaft.
9. Remove the clutch shaft bearing retainer if fitted.
10. GT-185: remove the clutch release lever cover from the bottom of the crankcase. Then remove the clutch lever and cable adjuster.

Clutch lever alignment marks (GT-185)

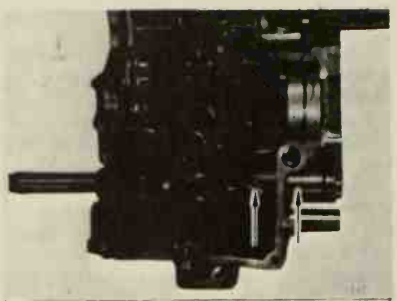
11. Remove the crankcase bolts on the upper and lower crankcase. A number stamped on the case near each bolt indicates the loosening *and* tightening sequence. If any bolts are fitted with two washers, they should be noted, and the washers must be in place when installing.

Tap around the mating surface of the crankcase halves with a plastic hammer to separate them, then separate the cases.



NOTE: *On the GT-185, the crankshaft and gear clusters will remain in the upper crankcase half, but on all other twins, they will be situated in the lower case half.*

Inspection



Inspection of the crankcase components is the same as for single-cylinder engines, previously outlined. Note that on twins, the crankshaft bearings must be removed from the crank with a special puller if defective.

Assembly

1. Reverse the disassembly procedure.
2. The crankshaft bearings must be correctly aligned. On most models, dowel pins in the crankcases are used, and they should seat in the corresponding holes in the bearings. A punch mark on the bearing is also used, and these must be positioned vertically.
3. Transmission shaft bearings are located either with dowel pins or with half-rings, both of which are installed in the crankcases. Make sure that these locators are in position in the cases before assembly.

Where fitted, crank bearings must have their pins seated in the crankcases

When installing the kickstarter shaft (GT-185) be sure that it is positioned as shown, with the holes upward

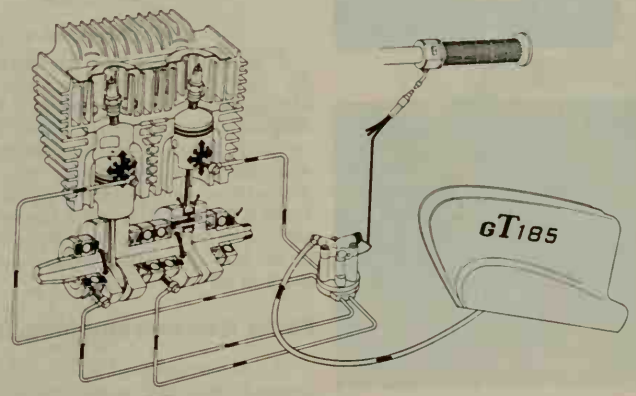
LUBRICATION SYSTEM

OPERATIONAL DESCRIPTION

All of the machines covered in this volume are equipped with Suzuki "CCI" (called "Posi-Force Injection" on early models).

This method, as the name "Cylinder and Crankshaft Injection" implies, involves the distribution of lubricating oil to the bearings of the crank assembly and to the cylinder walls by means of oil lines, rather than the more conventional gas-oil mixture. This allows the moving parts to receive a consistent supply of clean, undiluted oil which prolongs service life and cuts down on smoke emission.

The oil pump is gear-driven from the crankshaft, although the location of the pump (and the number of gears between it and the crank) vary according to model.



The discharge rate of the pump is controlled by cable which is connected to the throttle twist-grip. Since the pump speed is determined by engine rpm, the amount of oil discharged in a given time is dependent *both* on engine speed and throttle opening.

The oil is carried from the oil pump to the engine by means of external oil lines, each of which is fitted with a spring-loaded check valve which makes it impossible for oil to be forced back into the pump by crankcase pressure.

Oil Pump Location

1. On single-cylinder machines, except for the TS-250, the oil pump is located on the left-side of the engine usually just behind the engine sprocket.
2. On the TS-250, the oil pump is located in a compartment in the right engine cover almost directly around the crankshaft.
3. On early twin-cylinder machines, the pump is beneath a cover on the right-side rear portion of the engine.
4. On late-model twins, the pump is located on top of the crankcase behind the right cylinder.
5. In most cases (except the TS-250), the pump is driven off the kickstarter shaft.

NOTE: *In all of the following procedures, "oil" refers to Suzuki CCI oil or other recommended brands of two-stroke engine oil.*

CCI system

SERVICE

Under normal conditions, lubrication system service is confined to adjusting the oil pump cable and cleaning the oil tank filter.

If the oil tank, pump, or lines are removed or disconnected for any reason (such as engine removal), the lines should be bled of possible air bubbles.

CAUTION: *Due to the exacting tolerances to which it is made, the oil pump should never be disassembled. If any lubrication system malady is traced to the pump, the unit must be replaced rather than repaired.*

Troubleshooting

First check that the CCI tank has a sufficient supply of oil. Then, refer to the following:

1. In the event of piston seizure or overheating not caused by component failure or incorrect timing, check the oil pump cable adjustment. Check that the breather hole in the CCI oil tank cap is clear, or that the tank breather tube (if so equipped) is not blocked off.

Oil pump air bleed screw

Check for air in the oil lines (see "Bleeding"), defective check valves, or low quality oil.

2. In the case of excessive smoking at the exhaust pipe, check the oil pump cable adjustment, faulty check valves, or low quality oil.
3. In the event of excessive oil consumption, check the pump cable adjustment, and then for oil leakage at the pump line banjo bolts.

NOTE: *If abnormal oil consumption*

occurs, and assuming that the cable is properly adjusted, the pump should be replaced, and a known, properly operating pump substituted. If this does not cure the problem, suspect the check valves.

Bleeding

Before attempting any bleeding operation, ensure that the oil tank has a sufficient quantity of oil.

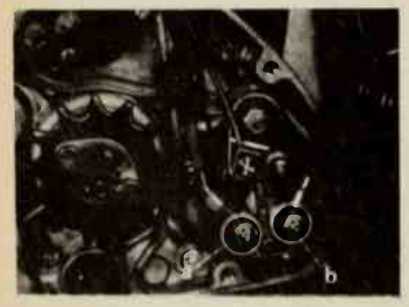
The oil pump is fitted with a phillips head bleed screw. Refer to the illustrations.

1. If air bubbles are present in the line from the oil tank to the pump, loosen the bleed screw and observe the oil flow. When the oil is free of bubbles, retighten the screw.

2. Check the lines from the oil pump to the engine for bubbles. If present, they may be removed in either of the following ways, depending on the amount of air present in the lines:

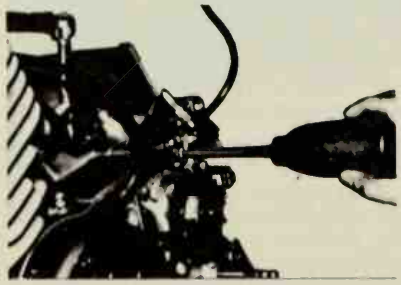
a. If few air bubbles are present, start and run the engine at approximately 2,000–3,000 rpm while holding the oil pump lever full on, until you feel that all of the air is expelled from the lines.

b. If a larger quantity of air is present in the lines, the procedure will vary according to model, but for all models the oil lines from the pump to the engine will have to be filled with oil by hand.



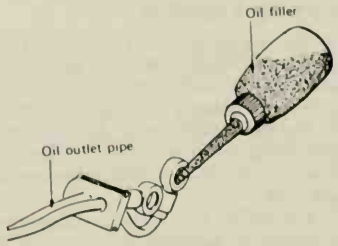
c. If the pump is mounted on top of the crankcase, remove it (see "Removal"), and force clean oil into each of the oil feed lines as shown, until they are full. After installing the pump, carry out procedure "a" above.

d. If the pump is mounted on either side of the crankcase, it is fitted with two outlet banjo bolts, one for each of the pump-to-engine feed lines. If the banjo bolts are equipped with phillips head screws, remove them, and force clean CCI oil into the lines until they are full, then replace the screws. Tighten them securely.

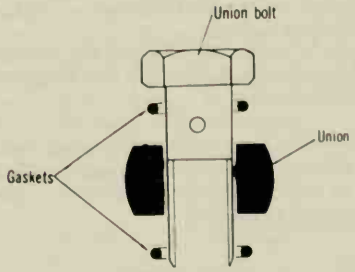


If the bolts are not equipped with these screws, it is necessary to remove the bolts. Then fill the lines as described.

Forcing oil into the CCI lines



Oil pump banjo bolts (a and b)

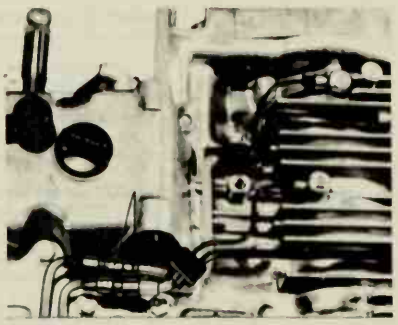


Injecting CCI oil into the lines on the pump

In both cases, carry out procedure "a" above, after the banjo bolts or screws are installed.

CAUTION: *Before installing banjo bolts, check that the gaskets, which must be fitted on both sides of the banjo, are in good condition. Use a thread locking compound on the bolt threads. Tighten the bolts to 2 ft lbs.*

Injecting oil into the CCI lines after removing the banjo bolts



Banjo bolt gasket positions

3. In the event that the lines cannot be freed of air bubbles, the system should be checked for air leaks. With the engine running, squirt clean CCI oil onto the banjo connections at the pump and engine, on the oil line connections, and around the pump-to-engine mating surface. If the air bubbles stop temporarily during this operation, the system has an air leak. Suspect damaged gaskets or cracked oil lines.

Pump Removal and Installation

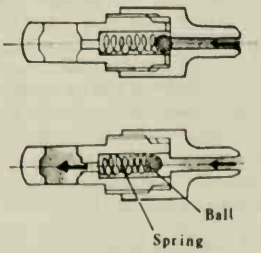
1. Remove the oil pump cover. If the pump is mounted on the left-side of the engine, disconnect the drive chain.

CCI check valve location

2. Disconnect the pump cable from the lever. Disconnect and plug the feed line from the oil tank.

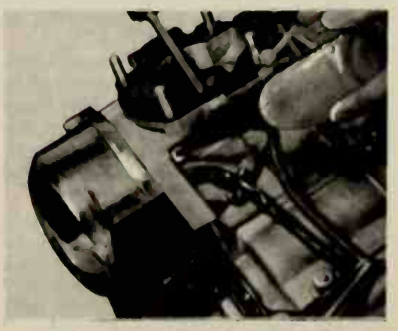
3. Remove the inlet banjo bolt at the oil pump, if accessible.

CAUTION: *Since most models are fitted with OUTLET as well as inlet banjo connections, be sure to note the location of the inlet line before removing the bolt. Reversing the connections upon installation will cause damage.*



4. Remove the outlet line banjo bolts on the pump body (all models except late-model twins).

5. Remove the securing screws, and remove the oil pump.



6. If the pump-to-engine feed lines are removed, blow them clear. Check the external condition of the lines and gaskets. Replace any damaged components.

7. A crude check of the check valves can be made by attempting to force air "backwards" (engine-to-pump) through the feed lines. The check valves should form an effective seal. If defective, the valves must be replaced, as service is not possible.

8. If the oil lines have been removed, force oil into the crankcase passages, as shown, before installing the lines.

Check valve operation

Injecting oil into the crankcase banjo fitting

9. Reverse the removal procedure. Oil pump mounting screws should be torqued to 1.5–2.9 ft lbs. Oil lines (pump-to-engine) should be filled with clean CCI oil before refitting the banjo bolts on the pump. (See "Bleeding").

Use thread locking compound on the banjo bolts and torque them to 2 ft lbs.

10. After reconnecting the tank oil line, bleed the line as previously described.

FUEL SYSTEM

NOTE: *For carburetor theory, component inspection, and troubleshooting, refer to "Carburetors" in the "General Information" section.*

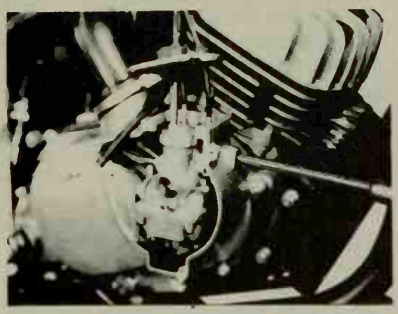
CARBURETOR

All models use Mikuni carburetors of the conventional concentric float bowl type.

Removal and Installation

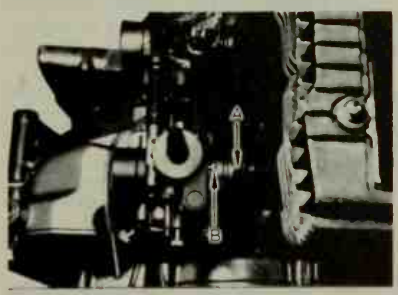
ROTARY VALVE MODELS

The carburetor is located beneath the cover at the forward end of the right-side engine case.



1. Lift up the rubber carburetor cover. Remove the carburetor cover plate. Remove the rubber plug on the front of the engine case.
2. Shut the fuel petcock off; disconnect the fuel line and overflow tube from the carburetor.
3. Unscrew the carburetor clamp which is accessible through the plug hole on the side case.
4. Pull the carburetor off its spigot, then unscrew the carburetor cap and pull out the throttle slide assembly.
5. Unscrew and remove the starter plunger from the carburetor body.

PISTON-PORT MODELS, SINGLE CABLE



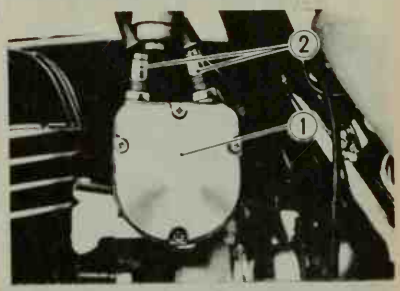
1. Disconnect the air cleaner from the carburetor. Shut off the fuel petcock, and disconnect the fuel line(s) from the carburetor(s). Disconnect the carburetor overflow tubes (if fitted).
2. Unscrew the carburetor cap, and pull out the throttle slide assembly. On models with a cable-controlled choke, unscrew and remove the starter plunger components from the carb body.
3. If the carburetor is mounted in a rubber spigot-type manifold, loosen the clamp screw, and remove the carburetor from the machine. On twins, remove both carbs at the same time if balance tubes connect them.

CAUTION: *GT-models use a pin-and-slot arrangement to ensure proper carburetor alignment. Therefore, the carbs must be pulled straight out of the manifold without tilting or twisting. Install in the same manner.*

4. If the carburetor is mounted with nuts onto a solid manifold, loosen each nut a small amount at a time until they are loose, then remove them and remove the carburetor from the machine.

Loosening the carb clamp screw (rotary valve models)

When removing or installing the carbs on GT-series machines, note the pin B must engage the slot A



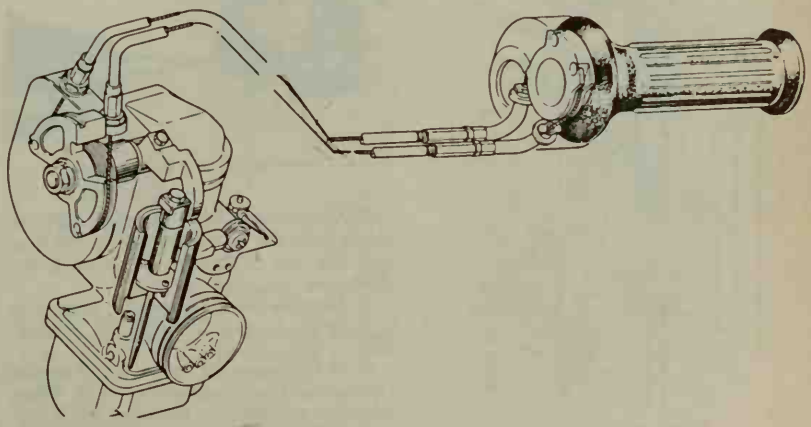
Removing the starter plunger components

CAUTION: *When installing this type, be sure that the rubber O-ring is properly seated in its groove on the carburetor flange. Apply some light oil to the groove, then press the O-ring on to ensure that it is firmly held in place. When tightening the mounting nuts, turn them equal amounts until tight. Do not overtighten.*

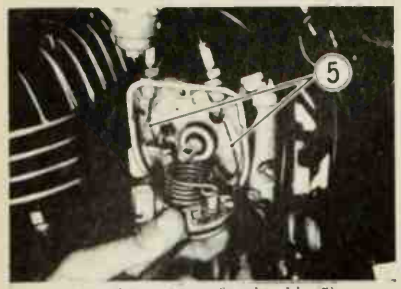
PISTON-PORT MODELS, DUAL CABLE

Late model singles, such as the TS-185A and TS-250A are equipped with a positive-action dual cable set up.

1. Shut off the gas and disconnect the fuel feed line from the carburetor.

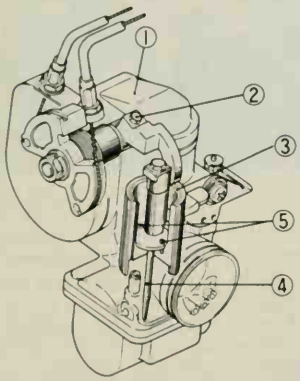


Pulley cover (1); cable adjusters (2)

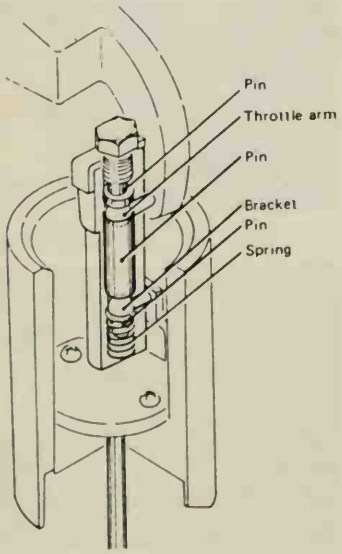


Remove the pulley nut (4) to remove pulley (3)

2. Slide the dust caps up off the cable adjusters on top of the carburetor. Remove the pulley cover which is secured by four phillips screws.
3. Loosen the adjuster locknuts and turn the adjusters in to give as much cable play as possible.
4. Remove the pulley nut and take off the pulley, disconnecting the cables from it.
5. Disconnect the cables from the carburetor, noting the position of each cable, or marking them so that they can be installed in their correct locations.



Dual-cable assembly



Note the position of each cable (5)

Disengaging the throttle cable from the slide

Carburetor cap (1); throttle slide shaft bolt (2); throttle slide (3); needle (4); needle securing screws (5)

6. Loosen the air cleaner and engine-side carburetor clamp screws, and pull off the carburetor.

Disassembly

IMPORTANT: *Note the location of all O-rings and washers when disassembling carburetor. Refer to the exploded views if necessary.*

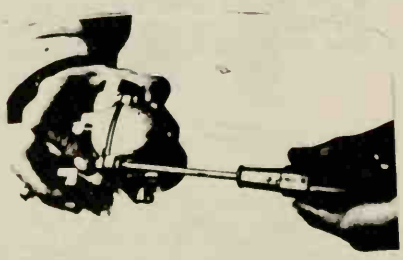
Procedures will vary slightly depending on the type of carburetor fitted.

To disassemble the throttle slide, proceed as follows:

a. On carburetors which have the throttle-stop (idle speed) adjuster on the carburetor top, remove the cotter pin which secures the rod to the adjuster. Disengage the cable from the slide and separate the components.

b. On single-cable carburetors with the throttle-stop screw on the carburetor body, compress the return spring, disengage the throttle cable from the slide, and separate the components.

c. On dual-cable carburetors, remove the two carburetor cap screws and take off the cap. Loosen the throttle slide shaft bolt and pull out the shaft. Remove the slide assembly. To remove the needle only, remove the two small phillips screws in the throttle slide. To disassemble the slide assembly, remove the bolt from the top of the arm and separate the components.



1. Unscrew and remove the pilot air screw and the throttle stop screw if this is mounted on the carburetor body.

2. If a drain plug or main jet banjo bolt is fitted to the float bowl, remove this now. Note that on some model "SH" carburetors, the main jet is threaded into the end of the banjo bolt.

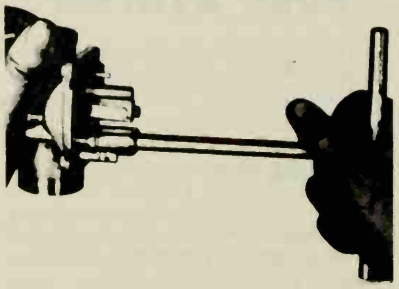
3. Remove the four phillips head float bowl screws, and carefully separate the float bowl from the carburetor body.

CAUTION: *Take care that the floats are not mishandled when the float bowl is removed.*

4. If an interconnected (one-piece) float is used, remove the float pivot pin by hand, and remove the float assembly.

Removing the float bowl screws

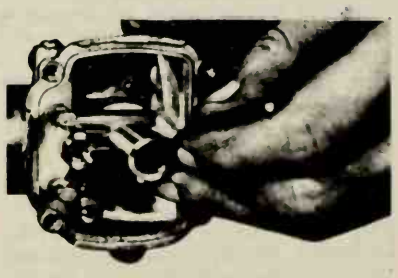
If independent floats are used, remove these from the float bowl. Take the float arm pin out by hand, and remove the float arm.



5. Remove the float needle, and, with a suitable socket wrench, the needle seat.

6. If the main jet is mounted in the carburetor body, remove it next. Then unscrew and remove the pilot jet.

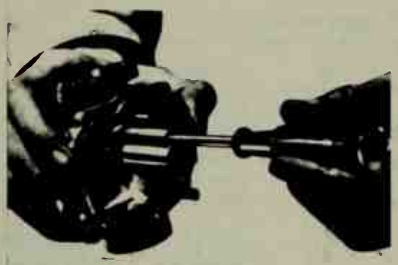
CAUTION: *Fuel jets are very malleable, and must be handled with care to avoid damage.*



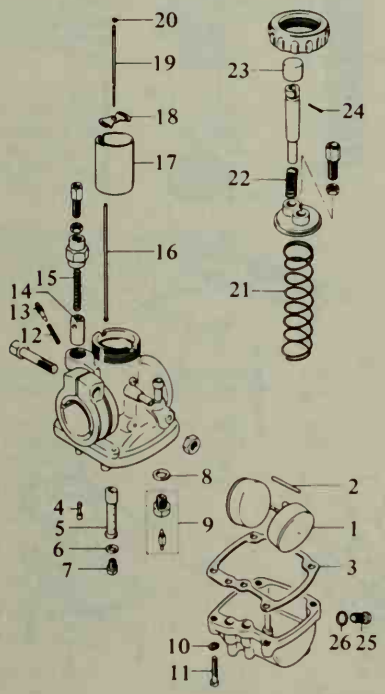
Removing the float pivot pin

Removing the float needle seat

Removing the main jet



Removing the needle jet



7. Remove the needle jet. On some carburetors, the needle jet is directly above the main jet, and is fitted with a hexagonal body so that a wrench can be used to unscrew and remove it.

On other carburetors which have interconnected floats, the needle jet is located some distance into the carburetor body. A wooden dowel is used to push the needle jet up and into the carburetor throat to remove it.

On carburetors with independent floats, carefully remove the rubber O-ring from the needle jet set-piece. Unscrew and remove the set-piece, then use a wooden dowel to push the needle jet up and into the carburetor throat and remove it.

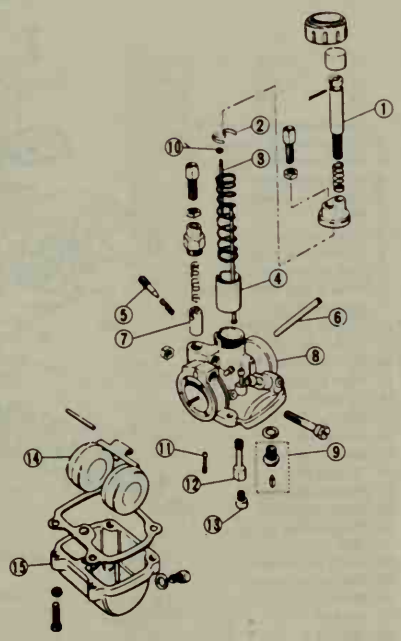
Assembly

1. Assembly is the reverse of disassembly. If a pressed-in needle jet with a cutout at the top is used, install the jet so that the cutout faces the rear (manifold side) of the carburetor.



2. On models with independent floats, be sure to install the floats with the pin toward the bottom of the bowl.

3. The condition of the rubber O-ring on the end of the needle jet setter is crucial and the O-ring must be replaced if it is not in perfect condition.

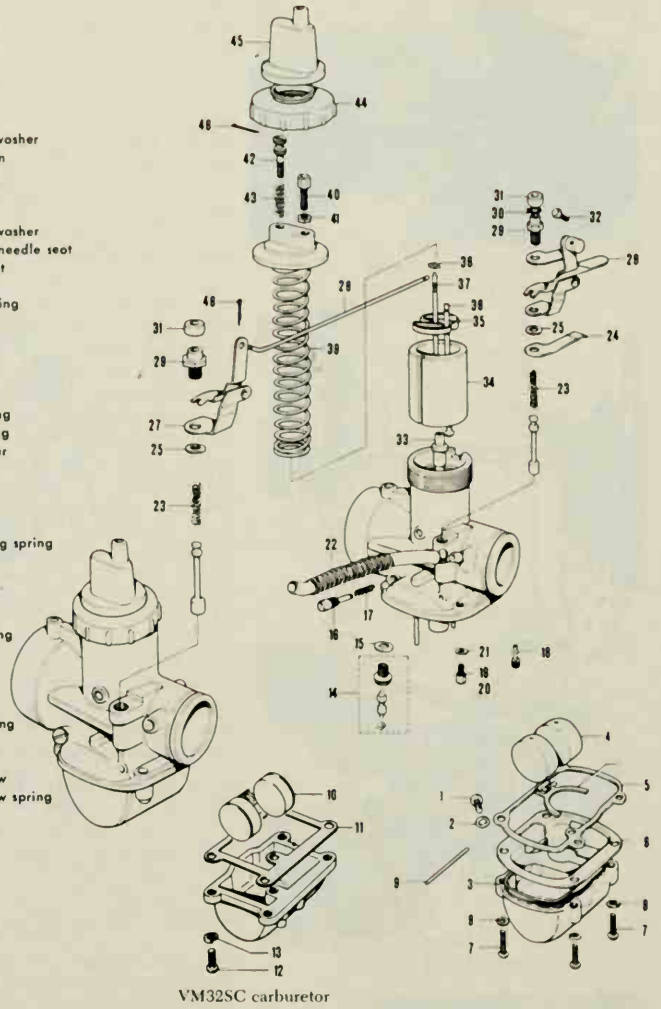
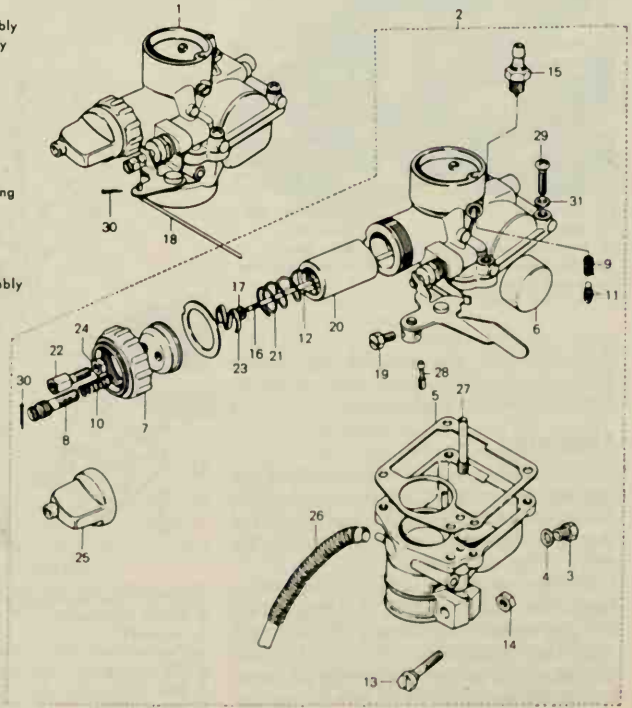
FUEL PETCOCK



1. Two types are fitted, depending on model and year: the vacuum-type and the standard gravity-flow type.

2. Both are fitted with sediment bowls (strainer cups) and screen filters. Periodically, the bowl should be removed and washed out in a solvent, and the filter cleaned.

3. The fuel lines should be inspected periodically for cracking or abrasion damage. Note that plastic fuel lines get brittle after some time, and at this point should be replaced.



4. Fuel lines should be so arranged that they contact the motorcycle only at the petcock and carburetor (except for rotary valve models). This will eliminate the risk of abrasion damage.

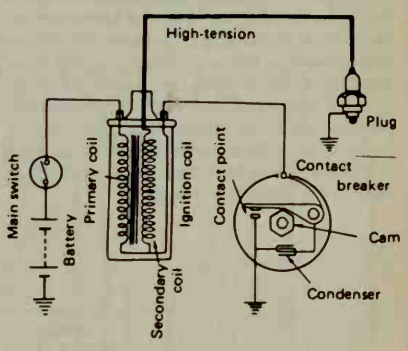
ELECTRICAL SYSTEMS

IGNITION SYSTEM

Conventional Ignition

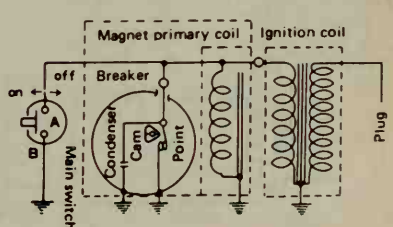
1. In the event of ignition system problems, inspect components such as the spark plug(s), points, and wiring connections.

2. Check the spark plug cap(s). The cap(s) are fitted with a resistor. Resistance should not exceed 20 K ohms. If it does, replace the cap.



3. A faulty condenser is often noticeable since it causes arcing and rapid burning of the points. To check the condenser, which is fitted to the breaker points plate, disconnect the lead to the condenser, and connect a continuity tester to the lead and to the condenser body. If the tester shows that continuity exists, the condenser must be replaced. An ohmmeter, connected in this manner, should show an infinite resistance.

4. The ignition coil primary and secondary windings can be checked in much the same way. The ignition coil is usually mounted beneath the gas tank.



To check the primary, connect an ohmmeter between the low-tension coil terminal and ground (magneto ignition), or if two smell terminals are found on the coil (battery ignition), connect the meter across the two of them. The meter should indicate 3–5 ohms for battery ignition machines, and 1–3 ohms for magneto-equipped models.

If readings exceed this amount, the coil should be replaced.

5. To check the secondary winding, connect the meter between the high-tension terminal of the coil and ground

Battery and coil ignition circuit

Magneto ignition circuit

(magneto ignition), or the high-tension terminal and low-tension terminal (battery ignition). Resistance should be 6–15 K ohms for battery ignition, and 4–7 K ohms for magneto machines.

If the readings are greater than the above, the coil has an open circuit. If substantially less, there is a short. In either case the coil should be replaced.

Magneto ignition systems have another coil that must be considered: the primary coil inside the crankcase. It will be necessary to remove the flywheel to test this coil. You will notice, after removing the flywheel, that there is a small coil wound on laminated iron connected to the ignition contact points. The other end of this coil is grounded. In addition, models up to 90 cc have a light coil; models over 90 cc have two light coils. Disconnect the primary coil lead from the points to isolate the unit, then connect the continuity tester. The bulb will light if the coil is unbroken, but to test for shorted windings it will be necessary to use the ohmmeter. The ohmmeter should read 1–3Ω when connected to the same points.

The primary coil laminated core should not be scuffed from contact with the inner surface of the flywheel. Normally there is about 0.015–0.020 in. running clearance between these units, which can and should be measured with the flywheel installed using bent feeler gauges.

PEI Ignition—TS-185, TS-250R-A, TS-400

WIRING HARNESS

The most common place where a problem might occur is in the wiring harness. An inspection should be made at the time of initial set up and at periodic intervals thereafter to see that all couplers are properly connected and are not shorting against each other or grounding against the engine or frame. If the motorcycle is to be used for competition, the lead wires should be taped to the frame to minimize movement which might lead to loose or disconnected connectors. CDI systems are susceptible to loss of electrical current if the connectors are dirty or corroded. Take care to keep all electrical connections clean and wherever possible keep the spark plug lead away from the frame.

MOISTURE

Care should be taken to protect the PEI system from moisture since water (particularly salt water) can cause corrosion at the connectors, leading to short circuits in the system. The connectors may be taped during competition to keep out moisture.

OHMMETER TESTS

If an ohmmeter is available, the PEI Black Box can be checked according to the following chart. If readings are not within specifications, service is by replacement.

Testing Black Box Connections with an Ohmmeter

Red (+) terminal to:	*Black (—) terminal to:*	*Reading (± 10 percent)*
Black/Red	Black/Yellow	No reading
Black/Yellow	Black/Red	5000 ohms
Red/White	Black/White	1700 ohms
Black/White	Red/White	No reading
Black/Yellow	White/Blue	Needle deflects
White/Blue	Black/Yellow	and returns
Black/White	Black/Yellow	No reading
Black/Yellow	Black/White	1500 ohms

Testing Coils with an Ohmmeter

Test	*Red to:*	*Black to:*	*Reading (All Models)*
Exciter coil	Black/ Red	Coil plate	220 ohms
Pulser coil	Red/ White	Coil plate	75 ohms
Ignition coil (primary)	White/ Blue	Ground	0.7 ohms
Ignition coil (secondary)	Black	Ground	12K ohms

PEI Ignition—GT-500A

The GT-500A uses a version of the PEI system which is substantially different from that used on single-cylinder models.

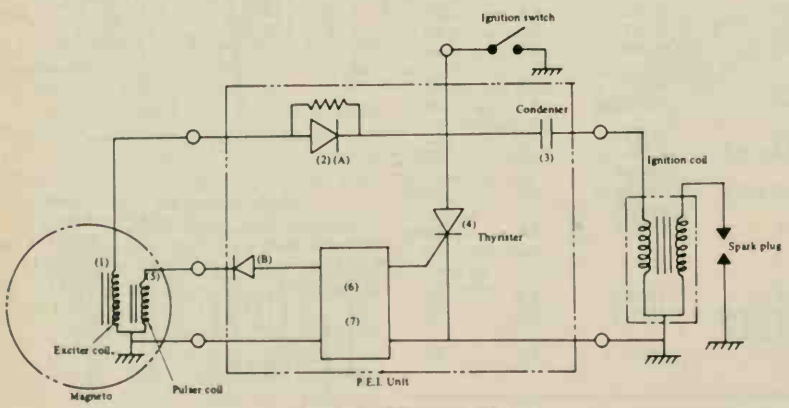
1. If the problem is in the ignition circuit, first check the ignition coil.

a. Measure the resistance between the two plug leads. It should be about 12 K ohms.

b. Measure the resistance between the white/black and black/white coil leads. It should be about 4 ohms.

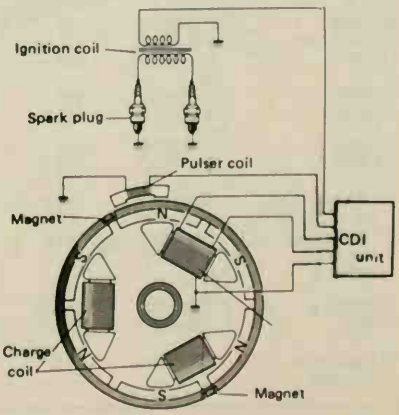
Values substantially higher indicate an open circuit, while lower readings are indicative of a short; in either case, readings which vary more than 10% from the standard specifications necessitate replacement of the ignition coil.

2. Check the resistance of the pulser coil across the red/white lead and ground. Standard is 67 ohms.



3. Check resistance of each of the exciter coils: green to ground (185 ohms) and black/red to ground (214 ohms). Replace the coil(s) if resistance is not within 10% of these values.

4. If all above components check out, the CDI unit must be checked next. The job is designed to be carried out by the Suzuki Pocket Tester (No. 09900-25001), although an ohmmeter can be substituted.



a. With the tester set on the 100 ohm scale, make test connections as shown in the following chart. Symbols are as follows:

0: resistance zero or very low
inf: resistance infinite
high: resistance very close to infinite
con: condenser check; needle deflects then returns to infinity

AC CHARGING SYSTEM

On magneto models, the charging system consists of one or two light coils and a rectifier to change the alternating current (AC) produced into direct current (DC) required to charge the battery. On battery ignition models, a true alternator, or AC generator, is employed. With the alternator, a rectifier assembly is also required.

Rectifiers are of two basic types, although they serve the same purpose. Selenium wafer rectifiers are used on most magneto models and older twins that have alternators, while the newer silicon-diode type rectifiers are used on late-model bikes.

Low-capacity magnetos use a simple, single-phase half-wave circuit. High-capacity magnetos use a single-phase all-wave circuit, and AC generators a single-phase full-wave bridge circuit. These circuits require one, two, and four rectifier units, respectively.

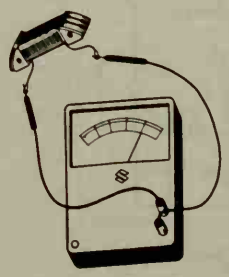
2. Lamp coil
3. Primary coil
4. Contact breaker
5. Condenser
6. Contact breaker cam oil felt
7. Flywheel rotor
8. Contact breaker fitting screw
9. Coil fitting screw

Testing the Magneto

1. An ohmmeter must be used. Resistance between the lighting coil leads should be about 1.5 ohms. If resistance is significantly lower or infinite, replace the coil(s).

2. The best way to test the lamp coil output is using the voltmeter and ammeter (or milliammeter). First, check out the battery voltage using the voltmeter, hooked up as per the magneto test schematic. It is important that the battery be fully charged before testing output, otherwise the results will not be accurate.



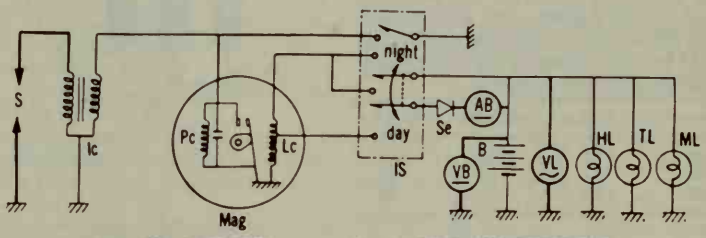
3. If the battery is fully charged, hook up the milliammeter, or better yet 0–5 DC ammeter if your tester has this range, as illustrated.

4. Start the bike and allow it to idle. No current will be shown at idle as a rule.

5. Speed the engine up to 2,000 rpm. At this speed, the output should be about 0.15 amperes, or 150 milliamperes, DC. If you don't have a 0–5 scale, you will have to stop here, otherwise the sensitive milliammeter will be damaged.

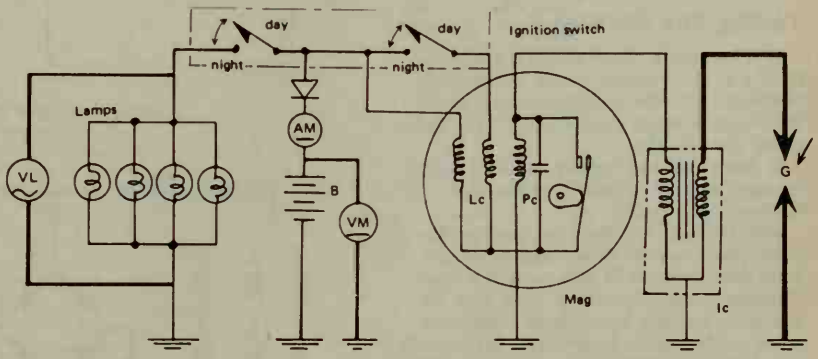
6. If you have this scale, speed up the engine to maximum rpm (about 8,000 rpm). The output should be 2.5–3.5 amperes DC.

7. Now, turn on the headlight high beam, or place the ignition switch in the headlight or night position. If all is well, output should be 100 milliamperes at about 2,500 rpm.



Checking resistance of the primary magneto coil

8. To check the light coil output, hook up an AC voltmeter as illustrated. Switch all lights on. At 2,000 rpm, output should be at least 6.0 volts, and at 8,000 rpm should be not more than 9.0 volts. If these figures are not attainable, check out the wiring, connectors, rectifier, and coils in that order. Sometimes the ignition switch itself is corroded or not making proper contact, so don't overlook it.



GT-500A Charging Coils

1. Resistance of the two charging coils is checked with an ohmmeter across the yellow/green and red/green leads and

then across the yellow/green and green/white leads.

2. In both cases, resistance should be within 10% of 1.0 ohms.

3. If resistance varies more than this amount from the standard, replace the coil(s).

Testing the Alternator

1. Hook up a 0–5 ammeter between the positive battery terminal and the wire removed from that terminal.

2. With the lights off, start the engine and gradually run it up to 2,000 rpm while watching the meter. The meter should begin to show a slight charge at this speed.

3. Run the engine up to 5,000 rpm and observe the meter. Charging current should be 1–2 amperes.

4. Turn on the lights and again observe the meter at 2,000 rpm and 5,000 rpm. Readings should be 100 milliamperes and 1.5–2.5 amperes respectively.

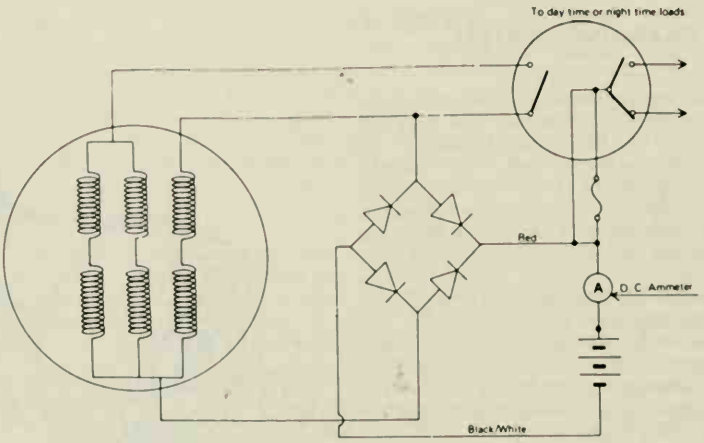
5. If the charging current is not to specifications, check the battery, rectifiers, and no-load voltage.

6. To measure no-load voltage, disconnect the wires from the alternator green/white, red/green and yellow/green wires. Connect an AC voltmeter of at least 0–100 volts between the alternator red/green and yellow/green wires.

7. Start the engine and check the output. With the rectifier out of the circuit, some idea of its condition can be ascertained. These figures may vary for different bikes, but the ratio between them should be approximately the same or the alternator could be defective.

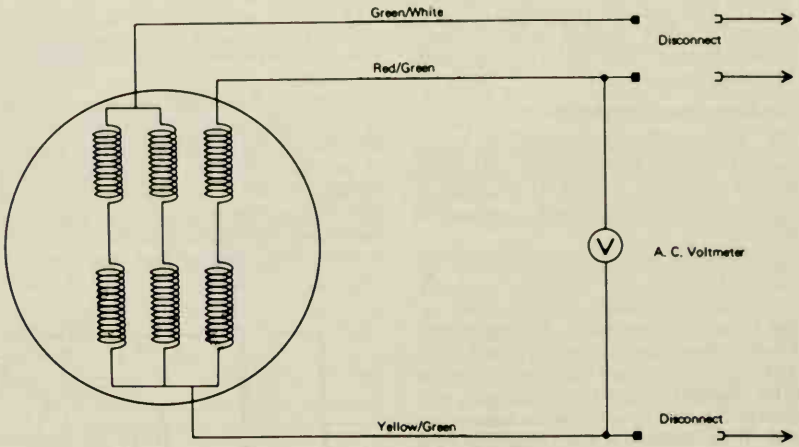
Engine rpm	*Normal*	*Minimum*	*Maximum*
2,000	23	17	33
5,000	49	40	60
8,000	82	70	95

Testing The Zener Diode Regulator



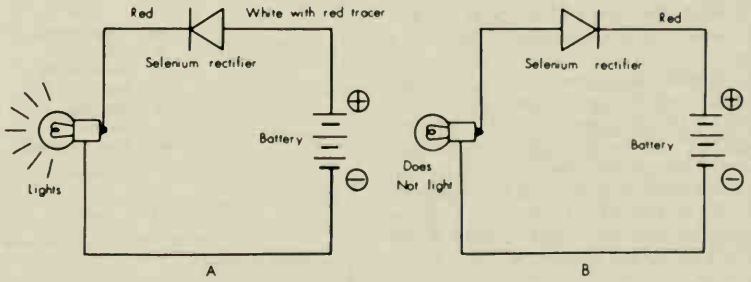
The Titan utilizes a zener diode voltage regulator that maintains battery charge voltage at 15.8–16.6 (GT500A: 14.0).

Testing The Rectifier



1. The easiest check of the regulator is to check the voltage across the battery terminals with the engine running about 4000 rpm. Voltage should conform to the given specification.

2. Note that the battery must be fully charged and all lights off, or the test results will be invalid.



Two types of rectifiers are used on Suzuki cycles: silicon-diode and selenium. Both these types will pass current in one direction only, therefore they can be tested by using a low-voltage continuity tester or ohmmeter. No current, indicated by a high resistance or an unlit bulb, will be shown when the test prods are connected between the rectifier terminals in one direction, but switching the prods should result in current flow. Compound rectifier units, having more than one rectifier inside, can be tested as per the illustration.

Testing the armature for continuity

DC STARTER-DYNAMO

This combination electric starter and DC generator is used on the GT-185.

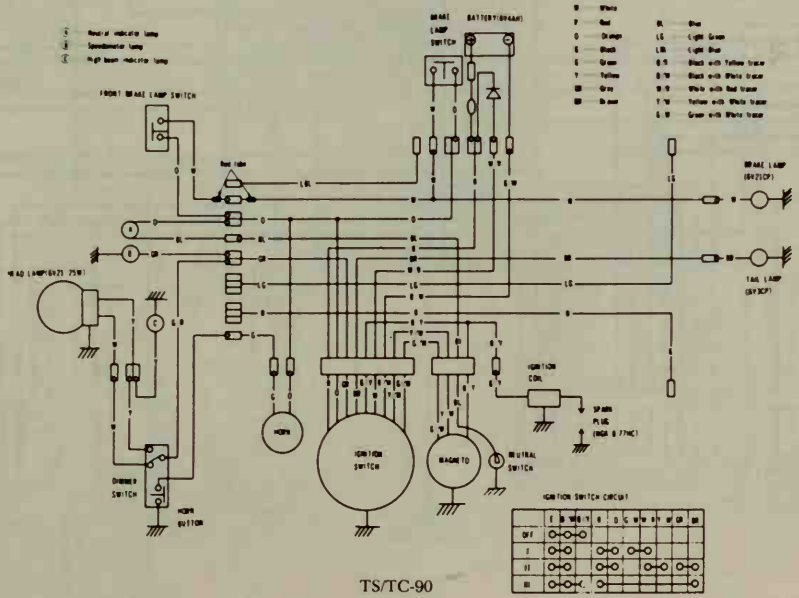
1. Check the voltage regulator first in the event of trouble. Disconnect the red lead from the regulator to the battery, and connect it to a DC voltmeter as shown in the illustration. Connect the other voltmeter lead to ground.

2. Start and run the engine. The voltmeter should indicate 15.4–16.6 volts at 3,000 rpm. If voltage indicated is higher or lower than this amount, the voltage regulator is probably defective.

3. Check for continuity in the generator wires. The generator should be removed from the machine.

Check for continuity between the yellow and red/green wires. Then between the green and red/green wires. In both cases, continuity must exist or the internal wiring is damaged.

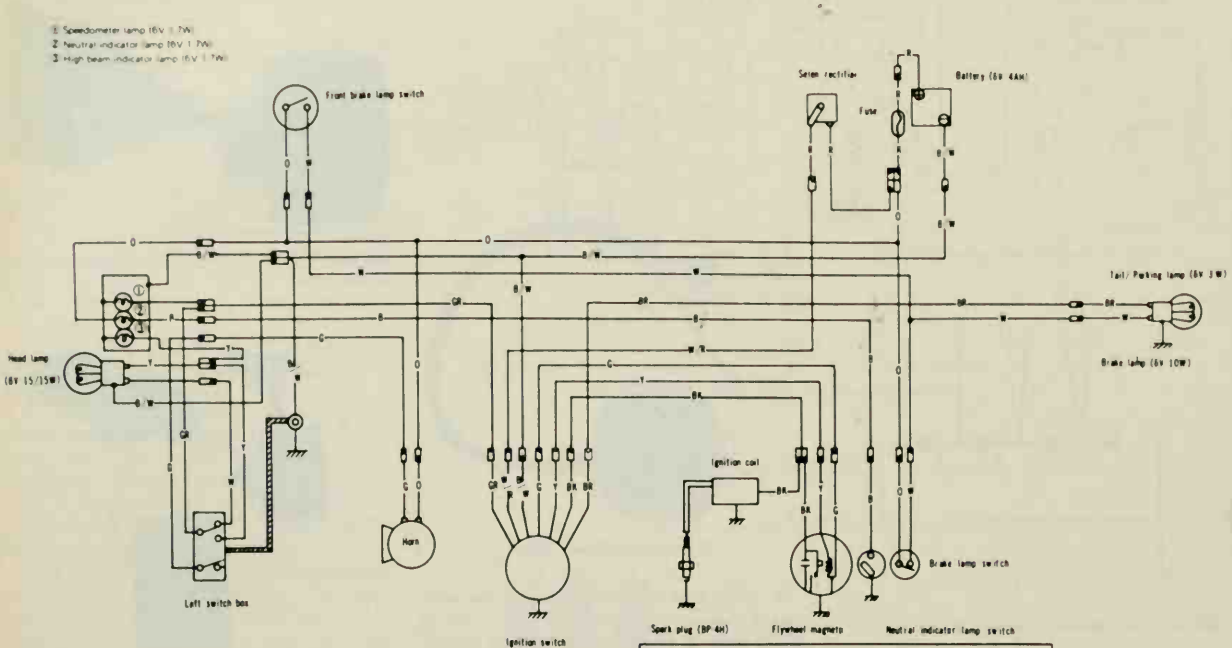
4. Check between the red/green wire and ground. There should be no conductivity. If there is, the generator field coil is grounded.



5. The armature commutator should be polished with fine sandpaper and wiped clean with a clean cloth.

6. Commutator mica undercuts should be 0.5 mm (0.02 in.), and can be brought within tolerance if the commutator is worn by recutting with a hacksaw blade.

7. Check for continuity between the armature commutator and the core as shown. If conductivity exists, the armature must be replaced.



8. Check the length of the carbon brushes. If they are less than 14 mm, replace the brushes.

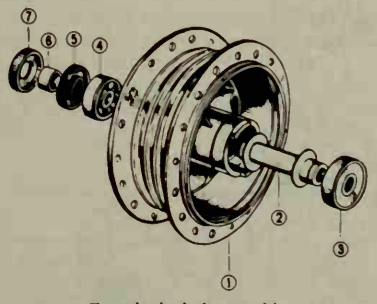
WHEEL AND HUB COMPONENTS

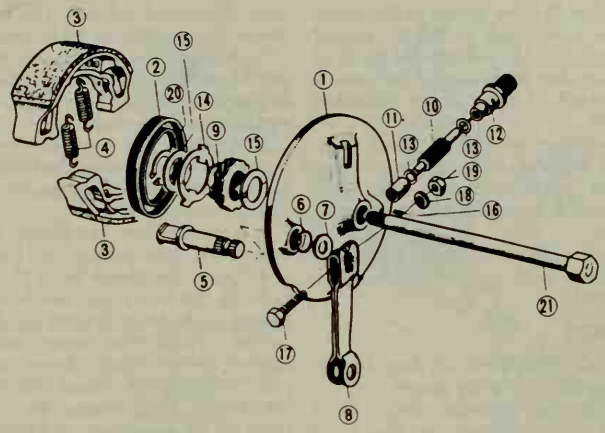
Wheel Removal and Installation

FRONT WHEEL

1. Two methods are used to mount the front wheel: the fork sliders may be fitted with removable caps to secure the axle, or may be one-piece with a pinch-bolt and an axle nut.
2. Before attempting to remove the wheel, support it off the ground.
3. Disconnect the speedometer cable at the hub, and the brake cable (if drum brake).
4. Remove the brake anchor bolt on drum brake models.



Removing the axle capnuts



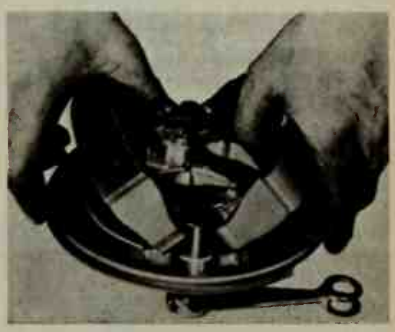
Loosening the axle pinch-bolt

5. If axle caps are used, remove the cap nuts (two on each slider), washers, and pull off the caps. Remove the front wheel.
6. If one-piece sliders are used, loosen the pinch-bolt on the slider, and unscrew the axle to remove the wheel.
7. To install, simply reverse the procedure. On disc brake models, slip the disc into the caliper carefully. Be sure that the anchor nut on drum brake models is firmly secured and the locktab bent up onto the flat of the anchor nut.

Front brake hub assembly

1. Front hub drum
2. Front hub bearing spacer
3. Ball bearing (sealed)
4. Ball bearing
5. Hub drum oil seal
6. Front axle spacer
7. Front hub drum dust seal

Front brake hub and single-leading shoe brakes



1. Front brake backing plate
2. Backing plate oil seal
3. Brake shoe
4. Brake return spring
5. Brake cam
6. Brake cam dust seal
7. Dust seal washer
8. Brake lever
9. Speedometer pinion
10. Speedometer gear
11. Speedometer gear inner bushing
12. Speedometer gear outer bushing
13. Thrust washer
14. Pinion drive
15. Pinion thrust washer
16. Outer bushing screw
17. Brake cam lever pinch-bolt
18. Lockwasher
19. Brake cam lever pinch-bolt nut
20. Circlip
21. Axle

REAR WHEEL

1. Remove the cotter pin and take off the axle nut.
2. Disconnect the rear brake cable (or rod). Disconnect the brake anchor at the brake hub.
3. On models which have the rear sprocket bolted to the hub, remove or raise the chain guard. Loosen the chain adjuster locknuts, push the adjusters down, then slide the wheel forward as far as possible and take the chain off the rear sprocket. Pull out the axle, and remove the wheel from the machine.
4. On models with a separate sprocket, remove the axle, remove the spacer, move the wheel as far as possible to the right to detach the wheel hub from the driving studs of the sprocket assembly, and remove it from the machine.
5. If this second type of wheel is used, the sprocket can be removed from the swing arm by removing or raising the chain guard, removing the sprocket nut, and taking off the sprocket.
6. Installation is the reverse of the above.

Drum Brakes

1. Inspect the brake linings for score marks, wear, or a grease or oil-soaked condition.
2. If scored or worn, the linings must be replaced. If scoring is severe, the brake drum should be checked for scoring and turned down on a lathe if necessary.
3. If the linings are oily or greasy, they must be replaced, and the source of the grease or oil found. Often, a defective wheel bearing seal will cause this.
4. Inspect the brake drum for scoring. If the brakes give an "off-on-off" feeling when applied lightly, the brake drum may be out of true. As in the case of scoring, the remedy is to have the drum turned down on a lathe.

Installing brake shoes

5. Check the condition of the brake springs, being especially attentive to rusted springs, or fatigued spring ends.
6. On most models, brake shoes are held in place by spring tension only, and the linings can be removed by grasping both of them and lifting them up and in toward the center of the drum. Installation is accomplished in the same manner.
7. After removing the shoes, the brake cam (or cams on twin-leading shoe brakes) should be checked. These can be removed from the brake plate by first removing the brake lever, the dust seal, then tapping out the brake cam. The cams should be cleaned thoroughly in solvent, and checked for corrosion or rust on the surface. This can be removed with emery cloth. Before refitting the cams, lubricate them with chassis grease. Do not forget to refit the dust seal.

Disc Brakes

Observe the following precautions when attempting work with hydraulic disc brake fluid:

a. use Dot 3 or Dot 4 fluid only;
b. never mix fluids from different manufacturers;

c. if fluid is to be added to the reservoir, use fluid from a tightly sealed container only. Do not use old fluid, or that which has been stored for even a short period of time in an unsealed container;

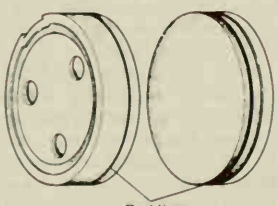
NOTE: *Never use fluid which has come in contact with water, or has been left open to humid air. Disc brake fluid is hydroscopic: it absorbs moisture.*

d. Do not allow brake fluid to come into contact with painted surfaces or plastic parts.

INSPECTION

Periodically check the hydraulic system, noting the following points:

1. The master cylinder fluid level should be approximately at the level mark. On late models, a see-through reservoir is fitted, so removing the cap and diaphragm to check fluid level is not necessary.



2. As the brake pads wear, the fluid level will drop slightly. It should not be necessary to add fluid, as the level will rise when new pads are installed.

3. If the fluid level drops below the level mark, carefully check the system for leaks. Check the hoses for abrasions or cracks, and the caliper for leaky seals.

4. Keep an eye on the pad wear. Replace the pads when they are worn to near the red limit line.

5. When the front wheel is removed, inspect the pads for scoring or abnormal wear, and replace them if necessary. Check the brake disc for scoring. This may be caused by foreign matter embedded in the brake pads.

6. Check that the hoses do not contact the frame or forks at any places except for their fastening points.

Replace both pads when either is worn to the red line

Maintain fluid level between the upper and lower lines

Bleeding

This procedure should be necessary only if any of the brake components has been disassembled, or if the brake level travel is excessive or feels spongy.

1. Remove the dust cap from the caliper bleed valve, and fit a suitable piece of plastic or rubber hose to it. A transparent hose is preferred.

2. Arrange the hose so that it loops upward, then immerse the other end in a clean container with a couple of inches of new brake fluid in it.

3. Squeeze the handlebar lever several times, then hold it hard on.

4. Open the bleed valve ½ turn while holding the lever on. The lever will be pulled to the twist-grip as the fluid is expelled. Hold the lever in position against the twist-grip; do not release it.

5. Tighten the bleed valve; release the lever; then repeat the procedure until all air has been expelled from the lines.

NOTE: *Keep track of the fluid in the reservoir during the bleeding operation, and refill it as necessary.*

6. After bleeding is complete, fill the reservoir to the proper level, refit the diaphragm, and secure the cap tightly.

PAD REPLACEMENT

1. Remove the front wheel.
2. Remove the securing screw and take out the inner brake pad.
3. Squeeze the brake lever and remove the main pad.
4. Apply a light coat of special brake pad grease to the sides and back of the main pad.
5. Open the bleeder valve slightly to relieve the pressure, then push the piston in all the way and close the valve.
6. Insert the main pad making certain that the groove is properly aligned with the positioning pin.
7. Install the inner pad, apply a small amount of thread locking compound to the securing screw, and tighten it firmly.
8. Install the front wheel. Bleed the system if necessary.

CALIPER

Removal

1. Remove the front wheel.
2. Disconnect the brake line at the caliper and use the rubber cover of the bleeder valve to plug the end of the brake line to prevent fluid loss.
3. If the caliper is to be disassembled after removal, loosen the two caliper (allen) bolts now.
4. Remove the mounting bolts and take off the caliper.

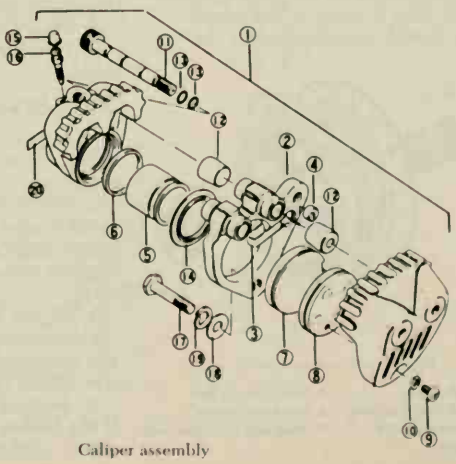
Disassembly

1. Remove the allen bolts and separate the caliper halves.
2. Remove the inner pad securing screw and remove the pad.
3. Remove the main pad.
4. Remove the piston dust seal. Use compressed air applied to the brake line connection to force out the piston. If this is not possible, it may be possible to remove it by reinstalling the caliper, connecting the brake line and applying the brake so that fluid pressure will force the piston out.
5. Remove the piston seal from the caliper taking care not to scratch the caliper walls.

Inspection

1. Clean all metal parts in new brake fluid only. Do not use solvents.
2. Measure the diameter of the piston and the inside diameter of the caliper bore, and compare the readings to the standard specifications and wear limits.
3. Check the sides of the piston and caliper bore for scuffing and replace the components if damaged.

Assembly



The use of new fluid seals, dust seals, and O-rings is recommended.

1. Coat the piston seal with new brake fluid and insert it into the caliper, ensuring that it is properly seated.
2. Lightly lubricate the caliper walls and sides of the piston with new brake fluid and install the piston in the caliper, being careful that the seal is not damaged when installing the piston.
3. Caliper allen bolts must be lubricated with special Suzuki grease before installation. The remainder of the procedure is the reverse of disassembly. Be sure the allen bolts' dust covers are in place.

Installation

Installation is the reverse of removal. Tighten mounting bolts to 22–26 ft lbs.

Tighten brake line nipple to 12–13 ft lbs. Bleed the system as outlined above.

MASTER CYLINDER

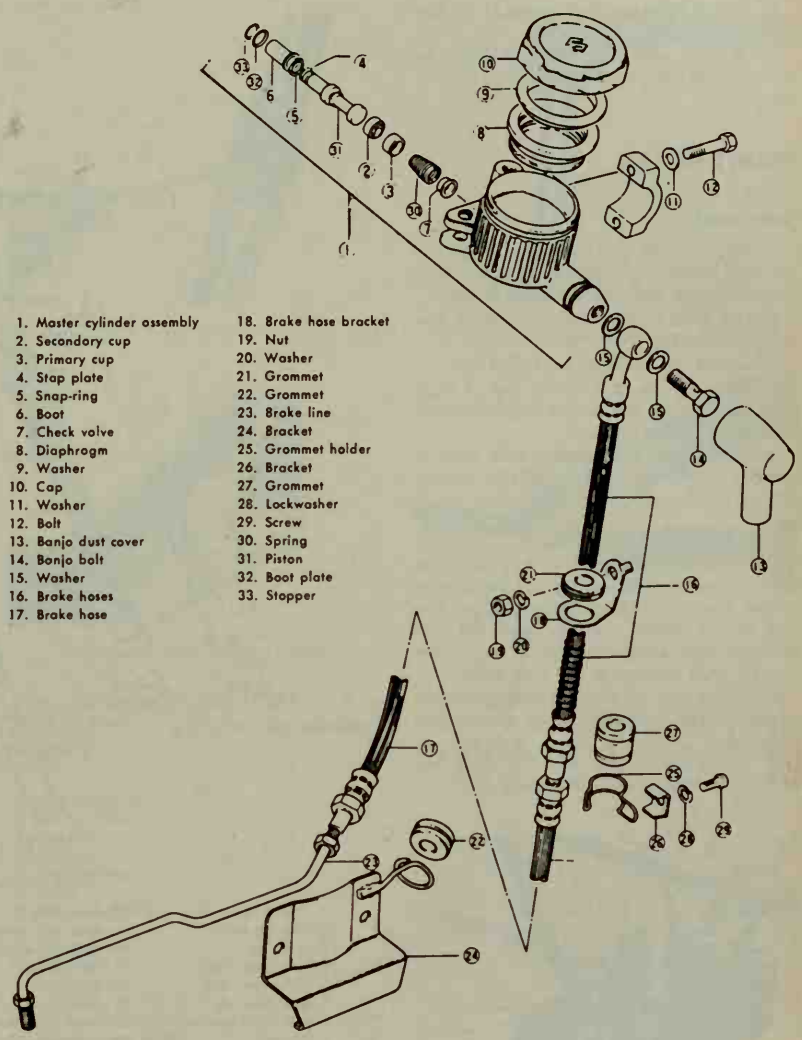
Removal

1. Disconnect the brake switch.
2. Disconnect the brake line at the master cylinder, taking appropriate precautions against fluid spillage.
3. Loosen the master cylinder cap and the brake lever bolt. Remove the mounting bolts and take off the master cylinder. Drain the fluid.

Disassembly

1. Remove the brake lever.
2. Remove the boot stopper, plate, and boot.
3. Remove the snap ring and take out the piston assembly.

Inspection



1. Clean metal parts in new brake fluid only.
2. Check piston and cylinder bore for wear against specifications given in the Disc Brake chart.
3. The use of new rubber parts such as the primary and secondary cup is recommended.

Assembly and Installation

1. Assembly is the reverse of disassembly. Lubricate all parts with new brake fluid before installing. Tighten the brake line banjo bolt to 18–24 ft lbs.
2. Bleed the system.

Brake Disc

1. Check the disc thickness and run-out and compare to the standard specifications.
2. Replace the disc if worn or scored. If run-out is excessive, first check that the wheel bearings are not worn.
3. If the disc is removed, tighten bolts to 11–18 ft lbs. when installing.

Wheel Bearings

1. Wheel bearings can be inspected in place for wear by inserting the axle into the wheel and noting any vertical or lateral play. If any is noted, the bearings should be replaced.
2. Oil seals are fitted to both sides of the hub and serve to keep the grease in the bearings. Once the seals are removed, they must be replaced with new ones.
3. To remove the bearings, first pry up the seals with a screwdriver and remove them from the hub.
4. With a suitably sized drift, drive each bearing out from the inside of the hub.

Removing wheel bearings from the hub

5. Wash the bearings thoroughly in a solvent. Inspect them closely by rotating each bearing, and noting any roughness, binding, or noisy rotation. If bearing rotation is not perfectly smooth, both bearings in the hub should be replaced.
6. Before installation, pack each bearing with wheel bearing grease, and add a small amount to the hub as well. Drive in each bearing until seated with a bearing driver or suitable substitute. Press in the seals afterward in the same manner.

Sprocket Assembly

1. After the rear sprocket is removed, check it for warpage and replace it if it is not very close to perfectly flat.
2. Inspect the sprocket teeth; if the teeth are worn or if they are hooked (usually in a direction opposite that of the wheel rotation), the sprocket must be replaced, and the engine sprocket and chain should both be carefully inspected for wear, or replaced.
3. Inspect the rubber shock absorbers in the wheel hub, and replace the rubbers if they are torn or otherwise damaged.

4. When refitting the sprocket to the hub, be sure to tighten the nuts in a cross pattern, and then bend up the lock-tabs so that they bear against the flats of the nuts.

FRONT FORKS

Removal

1. Support the front wheel well off the ground. Remove the wheel as previously outlined, and remove the front fender.

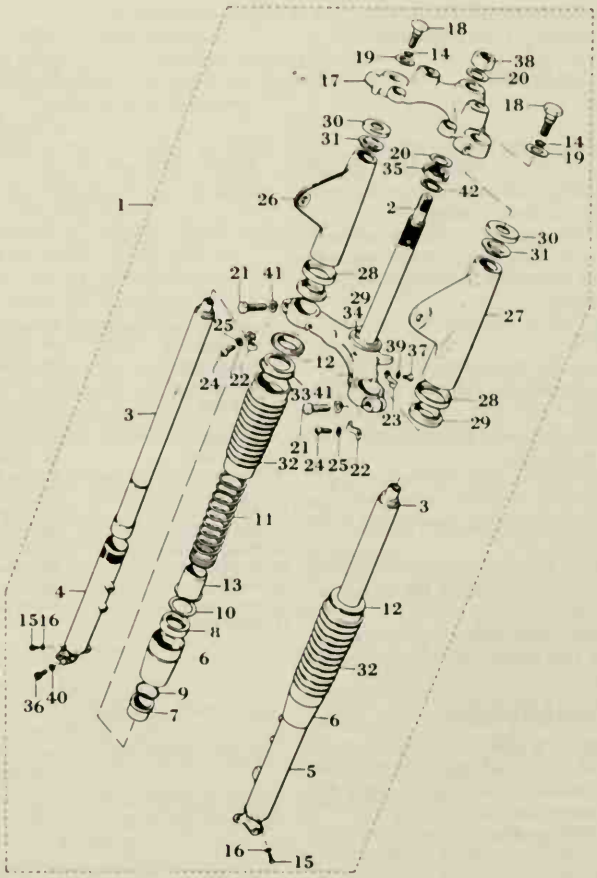
2. On disc brake models, unbolt the caliper from the fork slider.

3. Drain the oil from each fork leg.

4. Remove the bolt at the top of each fork leg. Loosen the upper and lower triple clamp pinch-bolts.

5. Grasp the fork slider and pull it sharply downwards. Repeat the procedure with the other fork leg.

Disassembly



1. After the fork top bolt has been removed, remove the fork spring guide, the spring spacer (if fitted), then take out the fork spring. Some models have only an external fork spring which is easily removed after removing the fork gaiter.

The fork can be further disassembled in one of the following ways depending on model:

2. Grasp the slider and the fork leg and spread them as far as possible.

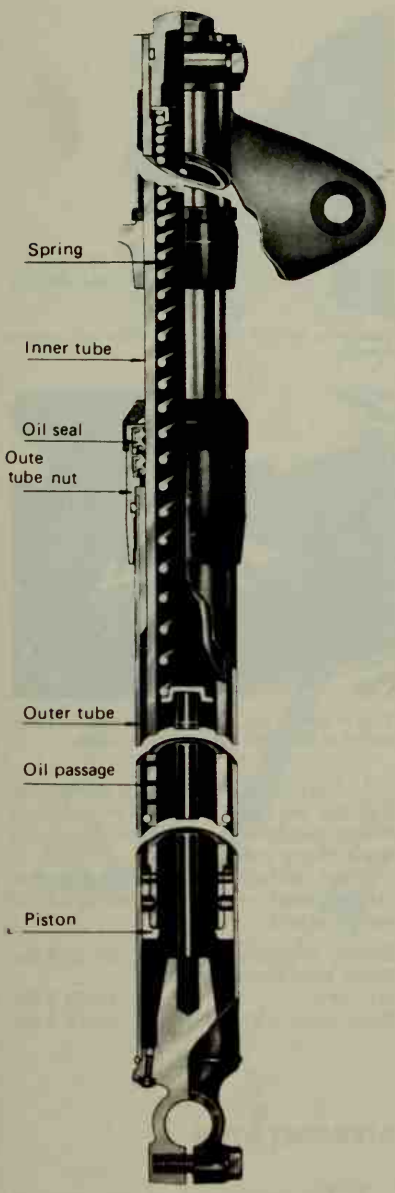
Removing the fork leg top bolt

Pull down on the slider to remove the fork leg from the frame



3. Lift up the dust cover fitted to the top of the slider. If a circlip is revealed, remove it.

On late models such as the GT-500A, this is all that is necessary for fork disassembly. The slider can be pulled off the fork leg after the circlip is taken off. On other models, however, the allen bolt at the very bottom of the slider must be removed. Then the components can be separated.

CAUTION: *Do not remove the slider allen bolt on GT-500A models.*

4. If no circlip is fitted, the fork has a circular nut threaded onto the top of the slider to secure it. To remove this nut, a strap wrench is used (as illustrated), while the bottom of the slider is clamped in a soft-faced vise.

If no strap wrench is available, it may be possible to remove the circular nut with a large heater hose clamp. After securing the slider in a soft-faced vise, tighten the heater hose clamp around the nut, then unscrew it with a vise-grip

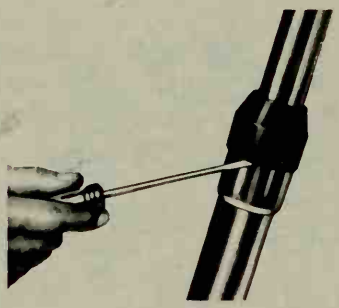
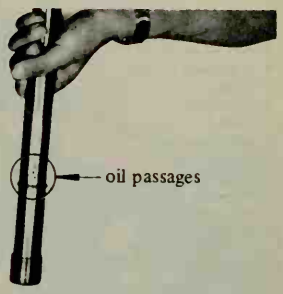
pliers applied to the screw fitting of the hose clamp. Then separate the slider from the fork leg.

5. Remove the slider O-ring if fitted. Then pry out the oil seal. New seals should always be used.



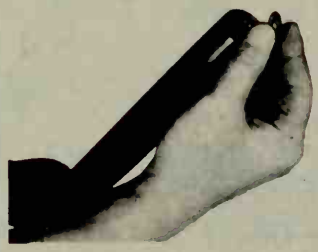
Inspection

1. Fork tubes must be free of rust or corrosion on both outer and inner surfaces.



2. Check that the tubes are perfectly straight. If they are bent, they should be replaced.

3. Check the condition of the fork springs. They must be of equal length. If one is shorter, or if either has collapsed coils, replace them as a set.



4. Inspect the damper tube, and insure that the holes are free of foreign matter.

5. Check the condition of the O-ring fitted to the fork top bolts, and replace if damaged.

but if it is too loose, it is probably worn and should be replaced. Check the condition of the slider bushing O-ring and replace it if damaged.

Assembly

1. Fork slider oil seals can be installed with a suitable drift. On some models, the slider should be placed on the fork leg and the seal installed with the slider in place.

2. Lightly lubricate all components with the recommended fork oil before assembly.

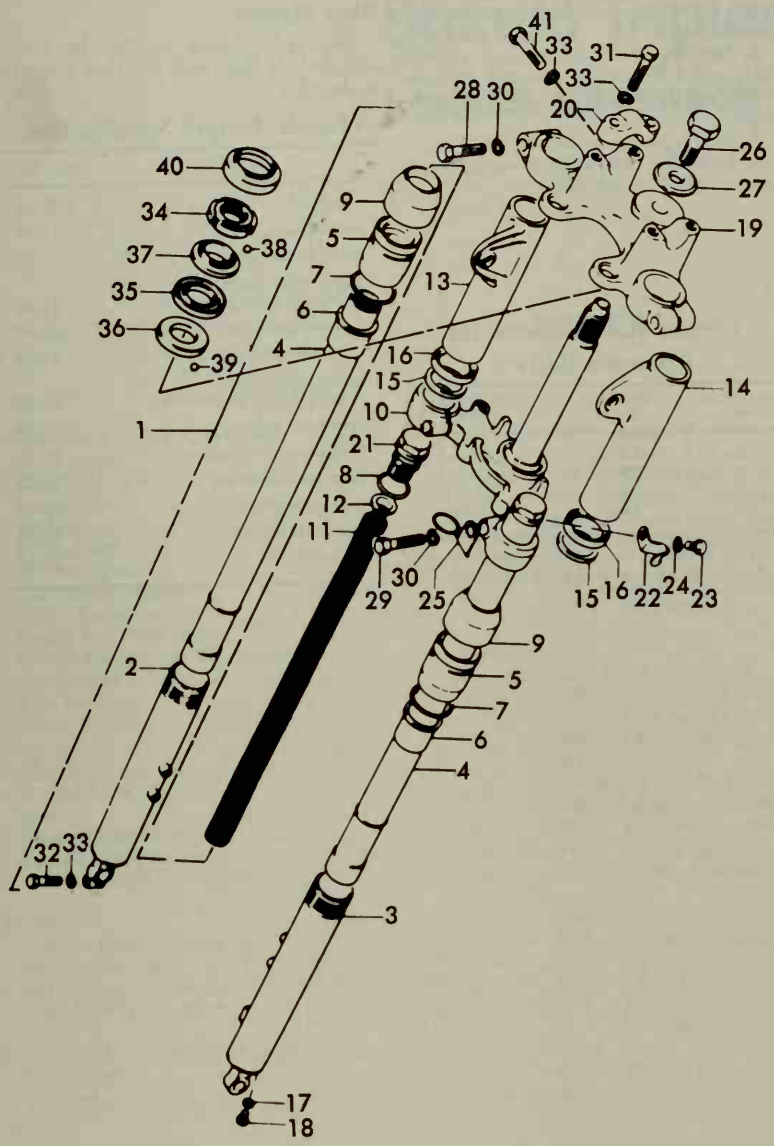
3. When the slider is assembled on the fork leg, install the leg into the triple clamp. On most models, the fork leg tops should be flush with the top surface of the upper triple clamp. On models where the legs protrude through the upper triple clamp, the distance should not exceed 5 mm (TS-250), 12 mm (TS-90) (see illustration) and must be equal for both fork legs.

Loosening the fork slider circular nut with a strap wrench

Tops of the fork leg should be flush with the upper surface of the triple clamp on most models

4. After installing the legs, tighten the fork leg top bolts, then the lower triple clamp pinch-bolts, and then the upper triple clamp pinch bolts.

When installing the hydraulic disc brake system, note the following torque specifications:



Caliper mounting bolts	22–26 ft lbs
Brake hose-to-master cylinder	18–24 ft lbs
Brake pipe (both ends)	12–13 ft lbs

STEERING STEM

1. The adjustment of the steering head bearings should be checked by supporting the front wheel off the ground, grasping the fork sliders, and attempting to move them back-and-forth in line with the machine. There should be no noticeable play if the adjustment is correct. If play exists, the bearing adjustment is too loose, and possibly the bearings are worn. Conversely, the front forks should be free to swing to either side of their own accord when released from any position. If they do not do this, the steering head bearing adjustment is too tight.

2. Moving the forks slowly lock-to-lock (with the front wheel clear of the ground) should yield a smooth, effortless feeling. If there is binding or loose spots in the fork action when moved in this manner, it is probably because the bearings or races are worn and should be replaced.

3. To adjust the bearings, remove the tach and speedometer, the handlebars, the large steering stem nut at the back of

the triple clamp, loosen the upper triple clamp pinch-bolts, and tap upwards with a soft-faced mallet to remove the triple clamp.

4. Loosen or tighten the adjuster nut with the special wrench or with a blunt punch and hammer. Recheck the adjustment.

5. If removal of the steering stem is necessitated by an inability to adjust the bearings correctly or to lubricate the assembly, remove the handlebars, fork legs, instruments, headlight and upper triple clamp, then remove the steering stem adjuster. While loosening this nut, put your hand beneath the lower triple clamp and hold it in position. When the nut is removed from the steering stem, very carefully lower the steering stem from the frame lug. Ball bearings will remain in the lower race, while the top set will be in the frame lug.

6. Wash the bearings and the races with a solvent and check their condition.

7. If any of the balls are rusted, pitted, or show flat spots, then all of them should be replaced. Should the surfaces of the races be pitted, rusted, or rippled, they should be replaced. Run your finger around the races; the surfaces

should be smooth and without indentations or other imperfections.

8. To replace the races, drive them out of the frame lug with a hammer and a drift. The race on the steering stem can be removed with a hammer and chisel. Install new races in the frame lug with a suitable drift. Be sure that the races are fully pushed home and that they are aligned before refitting the steering stem.

9. Smear the races with a good grade of bearing grease, and embed the bearing balls in the grease to hold them in place while the steering stem is installed.

10. After installation, adjust the bearings as described above.

SWING ARM

1. After removing the rear wheel and unbolting the shock absorbers at their lower mounts, check the swing arm for side-play. There should be none. If play exists, the swing arm bushings need replacement.

2. Remove the swing arm spindle nuts, and drift out the spindle. Pull the swing arm back and remove it from the frame.

3. Bushings can be driven out.

4. Lubricate the bushings with chassis grease before installation.

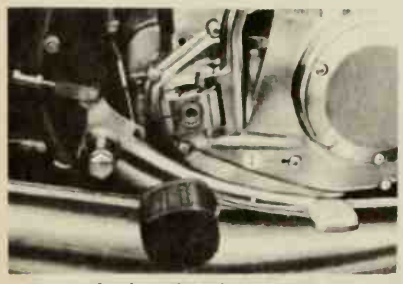
MAINTENANCE

NOTE: *Common maintenance procedures are explained in detail in "General Information."*

LUBRICATION



Engine

Suzuki recommends SAE 30W CCI oil for engine lubrication. If Suzuki CCI oil is not available, one of the types listed below will suffice.

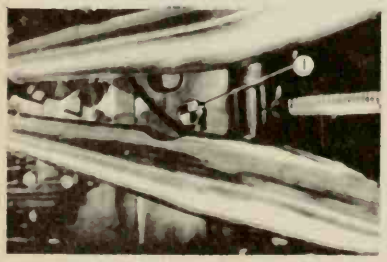
American	Permalube SAE 30W
Atlantic	Atlantic Aviation SAE 30W
Castrol	Heavy Duty SAE 30W
Gulf	Gulfpride SAE 30W
Humble	ESSO, ENCO, Humble SAE 30W
Kendall	Dual Action, Super Duty SAE 30W
Mobil	Mobil A SAE 30W
Phillips	Sixty-Six SAE 30W
Pure	Super Duty Purelube SAE 30W
Richfield	Richlube Premium SAE 30W
Shell	Shell X—100 SAE 30W
Texaco	Havoline SAE 30W

Gearbox

The gearbox (transmission) and clutch are lubricated by an oil bath. SAE 20W/40 is recommended for all models.

Gearbox oil level screw (1)

CHECKING OIL



A phillips head level screw is threaded into the right crankcase cover just behind the clutch housing. Check the oil level in the gearbox by removing the screw when the machine is parked on the centerstand on a level surface.

Oil should just begin to seep out of the level hole if the level is correct.

Check oil on warm engine.

CHANGING OIL

NOTE: *Oil should be changed when the engine is warm.*

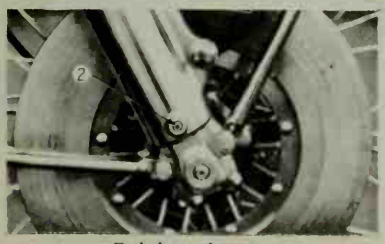
1. Every 2,000 miles (after break-in), remove the crankcase filler cap, remove the drain plug at the bottom of the crankcase, and drain the gearbox oil into a container.

2. Replace the drain plug, fitting it with a new washer as necessary, and add the correct amount and grade of oil through the filler cap.



3. Gearbox capacities are:
GT380J-K—3.0 pt (1420 cc)
GT380L-A—3.2 pt (1500 cc)
GT550—3.2 pt (1500 cc)
GT750—4.7 pt (2200 cc)

NOTE: *If the engine has been rebuilt, more oil will have to be added before operation. This is because the normal oil change procedure leaves a certain amount of the lubricant in the transmission. If the engine has just been reassembled add:*
GT380—3.2 pt (1500 cc)
GT550—3.4 pt (1600 cc)
GT750—5.3 pt (2500 cc)
Use the level plug to determine final level.

Front Forks

1. SAE 5W/20, 10W/20 or Automatic Transmission Fluid is recommended for the front forks.

2. To drain the fork oil, do one fork tube at a time. Place a container beneath the phillips head drain plug which is located at the lower portion of the fork slider. To drain the right fork tube, turn the forks all the way to the right; turn to the left to drain the left fork tube.

Fork drain plug (2)

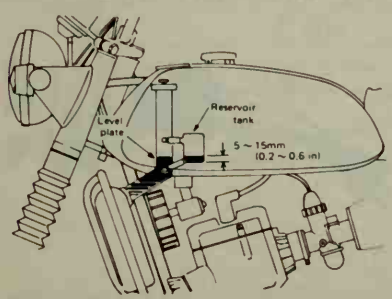
3. After the oil has been allowed to drain for a couple of minutes, pump the forks up and down several times to expel all of it. Check the drain plug washer for condition, replacing it if need be, then refit the drain plug, and remove the cap at the top of each fork.

4. Support the front wheel off the ground. Remove the filler cap at the top of each fork leg. Refill each fork tube with the correct amount and grade of oil. (Refer to the "Maintenance Data" chart at the end of this section.

Cooling System (GT750)

The cooling system capacity is 9.5 pt. (4.5 ltr). The system is filled at the factory with a solution of 50% antifreeze-and-summer coolant and 50% distilled water. This is the standard water-to-coolant ratio and it should be maintained unless the machine is operated in extremely cold weather. In this case, see the "Coolant Solution" chart for appropriate mixing ratios.

MAINTENANCE



1. Check the coolant level daily.

2. The correct solution level is 0.2–0.6 in. (5–15 mm) from the bottom of the reservoir tank. Refer to the illustration. Maintain the level at this point. Note that a white level plate is located in the radiator filler pipe for visual checks.

3. When adding coolant to maintain the solution level, use *distilled water only.*

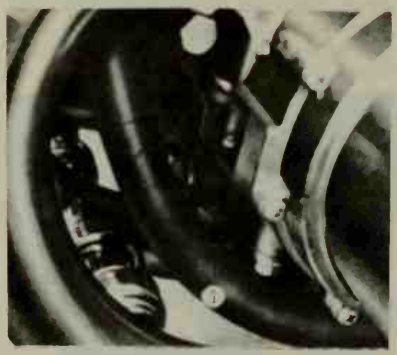
CAUTION: *Tap water must never be used because of the uncertain properties in various geographic locales (i.e., mineral content, etc.).*

4. Every two years or 20,000 miles, the cooling solution should be drained and refilled with a fresh amount. See below.

GT750 radiator water level

Coolant Solution

Operation in Air Temperature Below (°F)	Mixing Ratio of Antifreeze (%)	Amt. of Antifreeze/Distilled Water for 4.5 ltr (9.5 pt) (ltr)	(pt)
14	30	1.35/3.15	2.90/6.60
5	35	1.60/2.90	3.40/6.10
—4	40	1.80/2.70	3.80/5.70
—13	45	2.00/2.50	4.20/5.30
—24	50	2.25/2.25	4.75/4.75



FLUSHING AND CHANGING THE COOLANT

1. Remove the radiator cap. Remove the cooling system drain plug at the front, lower portion of the crankcase, and drain the solution.

2. Flush the system by running a garden hose or the like through the system for several minutes.

3. Replace the drain plug, and fill the system with water.

4. Start and run the engine for about ten minutes.

GT750 water drain plug

5. Drain the system completely, and refill it with the proper mixture of distilled water and antifreeze.

NOTE: *The drained water should be colorless; if not, refill and drain after running the engine as described above until the water is colorless.*

6. Add ½ oz. (14 gr.) of Suzuki "Bars Leaks" or another reputable radiator anti-leak formula. If in a liquid form, the proper amount is 70 cc (0.15 pt).

7. Run the engine for ten minutes, until the thermostat is open, then check the coolant level. Top it up with the correct mixture of distilled water and antifreeze. After running the engine until hot, once again check the coolant level.

CAUTION: *Do not mix different brands of antifreeze. Also, keep antifreeze off painted surfaces, since they will be easily damaged by contact.*

Carburetor Linkage

The carburetor linkage for 380 and 550 L-A models is fitted with a pair of grease fittings at the tops of the throttle slide shaft holders. Chassis grease should be applied to the fittings until excess appears at the shaft.

Drum Brake Camshafts

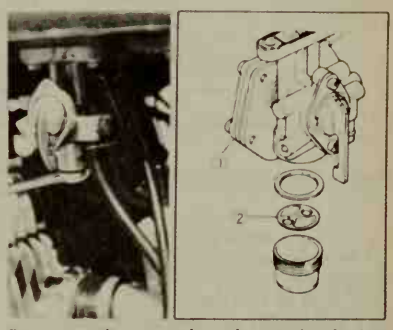
The brake opening cams should be attended to every 2,000 miles, and should receive a shot of chassis grease.

Swing Arm Pivot Shaft

Lubricate the swing arm pivot shaft with chassis grease every 4,000 miles.

SERVICE CHECKS AND ADJUSTMENTS

Air Cleaner



1. The air cleaner may be either the paper element or the polyurethane (foam) type.

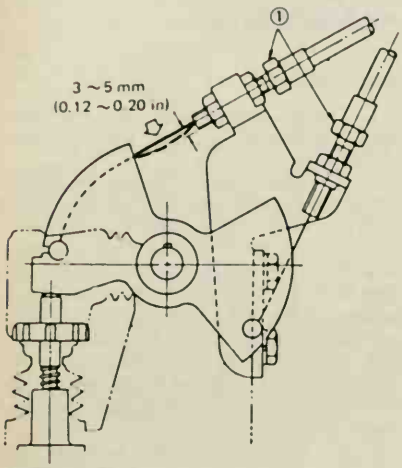
2. If a paper element type is fitted, remove it from the machine (every 2,000 miles or more often depending on conditions) by lifting up the rear of the gas tank slightly, removing the two air cleaner fitting bolts beneath the back of the tank, loosening the carburetor clamps, and taking out the filter. Clean by brushing off dirt, and blow off any remainder with compressed air applied to the inside of the filter. After 3 such cleanings, the element should be replaced.

3. If a "foam" type filter is fitted, remove it every 2,000 miles by removing the fitting bolts beneath the rear of the tank, loosening the carburetor clamps, and taking out the air cleaner from the right-side of the machine. Divide the cleaner case in two by removing the six nuts. Then take out the filter element by removing the two phillips head screws. Wash the filter in gasoline. Squeeze it dry. Then give the filter a light coat of CCI or SAE 30W oil, squeeze out the excess and reinstall.

Fuel Petcock

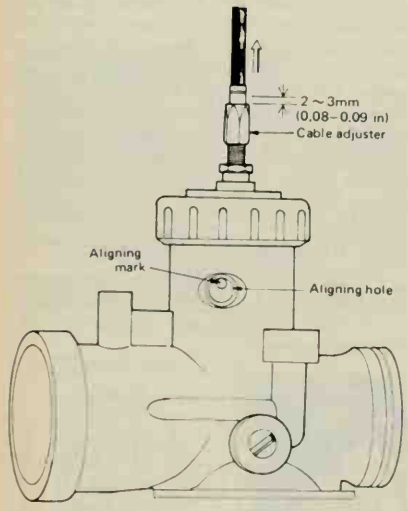
The petcock is fitted with a filter screen and this should be cleaned periodically in gasoline. Remove any sediment from the bowl as well.

Removing the petcock sediment bowl (left). Diaphragm case (1) and filter screen (2)



Throttle Cables

Throttle cable adjustment will depend on the type of linkage used. Generally, on SC-series carburetors, 1972–73, the cables should be set to have about 2–3 mm (0.08–0.1 in.) of free-play between the cable end and the adjuster on top of the carburetor for the GT550 and GT750; set the adjusters on the GT380 to give 3–5

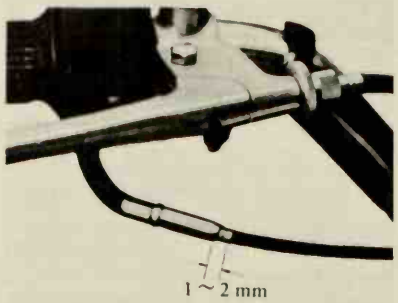


mm (0.1–0.2 in.).

1974 and later models use a dual-cable linkage. Use the cable adjusters at the carburetors so that when average thumb pressure (0.22–0.44 lbs./100–200 g) is applied to either cable mid-way between the cable adjuster and the pulley, the cable will be deflected 3–5mm (0.12–0.20 in.).

Be sure that both cables have the same free-play.

Each cable should have the same amount of free-play as illustrated (L-A models)



Throttle cable adjustment at the carburetor (GT550, GT750)

The cable adjuster(s) at the twist-grip should be set to allow 0.5–1.0 mm (0.02–0.04 in.) on the GT750, and 1.0–2.0 mm (0.04–0.08 in.) on the GT380 and GT550.

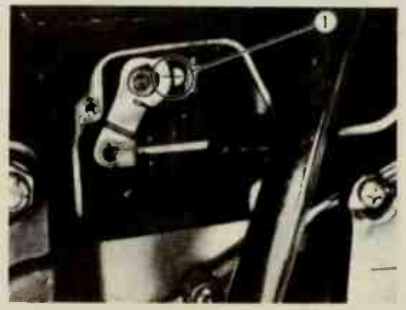
After setting this adjustment, idle the engine and turn the handlebars lock-to-lock noting any increase or variation in idle speed. If the revs go up, the cables are probably adjusted too tightly. Also check to make sure that the cables are not binding anywhere along the route from the twist-grip to the carburetors.

On "J" and "K" models, the throttle slides should be synchronized after setting the cable adjuster on the carburetor

Throttle cable twist-grip adjustment (GT380, GT550)

top and before setting the twist-grip adjustment.

Check the oil pump cable adjustment afterward.

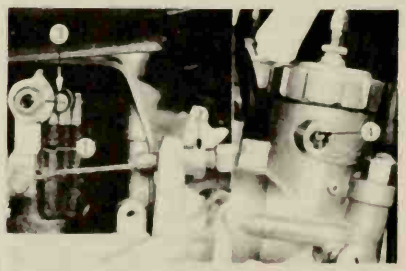


Oil Pump

NOTE: *Carburetor adjustments and throttle cable free-play must be set before the oil pump.*

GT750L-A

The oil pump rod adjustment can be checked after removing the oil pump cover. The lines on the pump lever and pump body should align.

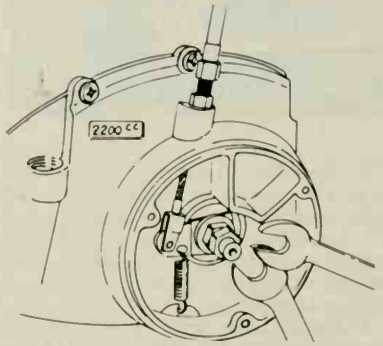


If the throttle is opened all the way, the punch marks should align.

Oil pump alignment marks (GT7501-A)

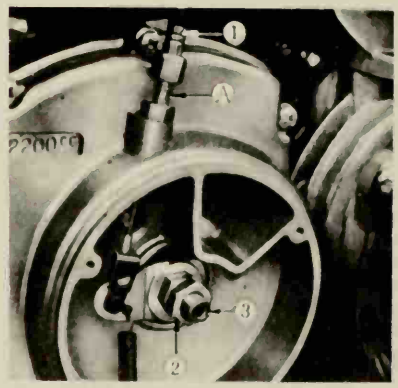
OTHER MODELS

1. Remove the oil pump cover.
2. Remove the carburetor slide alignment plug(s).
3. Adjust the throttle cable(s) as described above.
4. Turn the throttle so that the punch marks on the slides are at the top of the alignment plug holes.
5. At this point, the alignment mark on the oil pump lever should be lined up with the line on the pump body. If it is not, turn the pump cable adjuster in or out (after loosening the locknut) so that the marks align.



Proper oil pump cable adjustment. Note the position of the pump lever and the carburetor slide

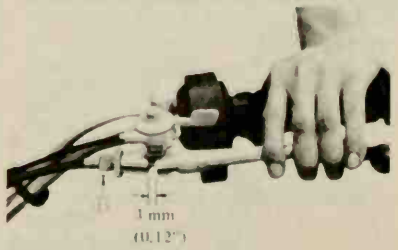
Clutch



Two adjustments must be made: the clutch adjustment itself, and the clutch cable adjustment.

GT750

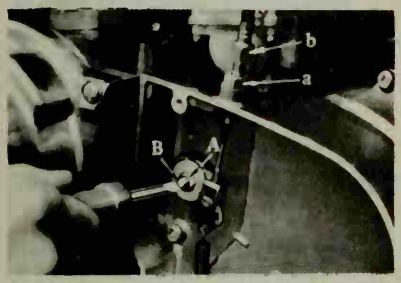
1. Remove the clutch cover.
2. Run down the cable adjusters either on the crankcase or at the handlebar so



Loosening the clutch adjuster locknuts (GT750)

Clutch adjuster (3) and locknuts (2) (GT750)

that the clutch lever (in the case) has a bit of free-play before clutch disengagement begins.



3. The lever should have about 0.018 in. (0.5 mm) of play. As necessary, loosen the clutch shaft locknut and adjust the inner nut until the proper amount of play is evident in the shaft. Tighten the locknut.
4. Adjust the clutch cable using the adjusters on the crankcase or the handlebar so that the clutch handlebar lever has 0.12–0.16 in. (3–4 mm) of play before clutch disengagement begins.

Setting clutch lever free-play with the handlebar cable adjuster (B)

GT380, GT550

1. Remove the clutch cover.
2. Run the clutch cable adjusters at the handlebar or the crankcase down so that the clutch cable has plenty of free-play.

Clutch adjuster screw (B) and locknut (A) (GT380, GT550)

3. Loosen the clutch adjusting screw locknut.
4. Turn the clutch adjusting screw in until a bit of resistance is felt, then back it out ¼–½ turn, and tighten the locknut.
5. Adjust the cable with the crankcase or handlebar cable adjusters so that there is about 0.16 in. (4 mm) of handlebar lever movement before clutch disengagement begins.

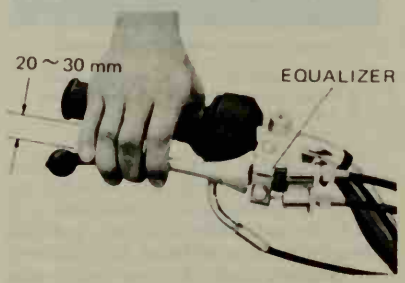
Drive Chain

The chain should have 0.6–0.8 in. (15–20 mm) of total up-and-down movement measured in the middle of the bottom chain run. The chain must be clean and well-lubricated before adjustment.

To adjust the chain:

1. Remove the rear axle nut cotter pin and loosen the nut.
2. Loosen both adjuster locknuts.
3. Back off the rear brake adjustment a few turns.
4. Turn the adjusting bolts IN to tighten the chain, OUT to loosen it.
5. Turn both adjusters equal amounts.
6. Check rear wheel alignment by referring to the adjusting marks scribed on the swing arm.
7. When the wheel is properly aligned, tighten the adjuster locknuts, the axle nut, and replace the cotter pin.
8. Recheck chain adjustment.

Brakes



DRUM BRAKES

Rear drum brakes should be adjusted so that the brake pedal moves about 0.8–1.2 in. (20–30 mm) before the brakes fully contact the drum.

Use the brake pedal adjuster, where fitted, to adjust pedal position for ease of operation. Then adjust the brake by turning the adjustment nut on the brake rod.

Note that the brake should be adjusted or at least checked each time the chain is adjusted.

Front drum brakes are four-leading shoe units on the GT550 and GT750. Both cables must be adjusted so that the brakes fully contact the drum when the handlebar lever is pulled about 0.8–1.2 in. (20–30 mm).

Front brake lever play before brakes contact the drum

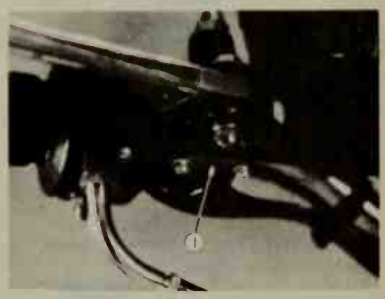
DISC BRAKES

Disc brakes need no attention other than an occasional check of fluid level and pad wear.

After removing the reservoir cap, note that the brake fluid level should be approximately at the level mark. 1974 and later models have a see-through reservoir, so cap removal is not necessary.

NOTE: *The fluid should be set at this mark when new pads are fitted or when the hydraulic system is overhauled or any component removed. The level will drop slightly as the pads wear.*

Check the brake pad wear, and replace them when they are worn to the red limit line.



Refer to the "Chassis" section for brake system service procedures.

If the brake lever feels spongy, bleed the system. This procedure can also be found in the "Chassis" section.

BRAKE SWITCHES

The rear brake light switch can be moved up or down on its bracket, to determine how quickly the brake light will go on when the brake pedal is applied, by moving the locknuts.

The front disc brake switch is similarly adjusted by loosening the switch securing screw and moving the switch forward or back.

Front brake light switch (disc brake)

Two types of contact breaker assembly

Contact breaker assembly components

1. Contact point base
2. Contact point set plate
3. Timing plate
4. Aligning mark
5. Movable plate

Both "Denso" and "Kokusan" contact breaker assemblies are used, and it is important to find which manufacturer supplied the assembly for your machine when ordering parts. Refer to the illustration comparing the two types of breaker assemblies.

Adjustment

NOTE: *Always clean the points before gapping.*

1. Turn the engine over until any one of the points is fully open. Check the gap with the appropriate feeler gauge. The acceptable point gap for all models is 0.30–0.40 mm (0.012–0.016 in.).

2. To adjust the gap, simply loosen the screw which secures the breaker point to its mounting plate; use a small screwdriver to move the breaker point by means of the small slot cut out of the assembly, until the correct gap is obtained.

NOTE: *The right and center breaker points (indicated by letters "R" and "L" stamped on the base plate) are mounted on movable mounting plates which are fastened to the base plate by two screws. These two screws are loosened to adjust ignition timing only, and it is not necessary to disturb them to set the point gap.*

Also note that the points for the left cylinder are mounted directly on the base plate; but it is still necessary to loosen only a single screw to set the gap.

4. Tighten the adjusting screw, and recheck the gap with the feeler gauge.

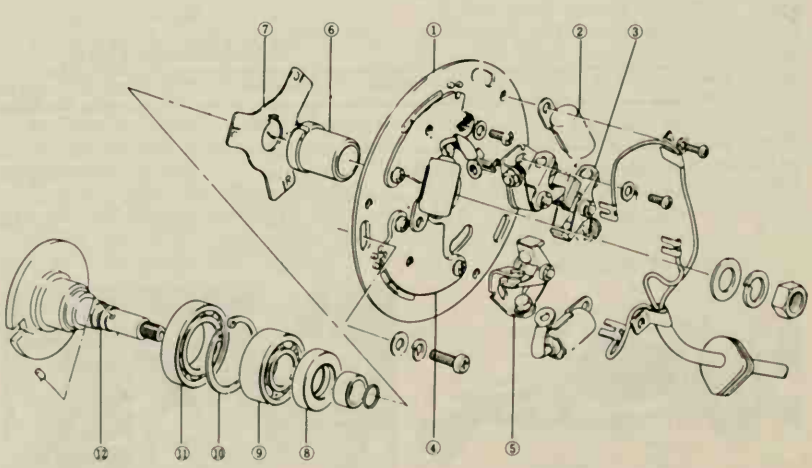
5. Repeat this procedure for the other two cylinders.

IGNITION TIMING

A dial gauge (to determine piston position) is necessary for ignition timing. Since all three machines use battery-and-coil ignitions, a test or continuity light or an ohmmeter/point checker can be used to find when the points separate.

TUNE-UP

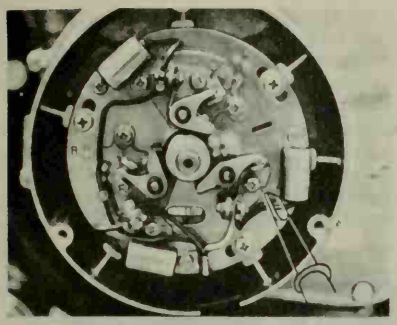
NOTE: *Common tune-up procedures are explained in detail in "General Information."*



CONTACT BREAKER POINTS

Replacement

NOTE: *New points are coated with a preservative to prevent the contact surfaces from rusting. Be sure to remove the coating with a solvent before installing the points.*



1. To replace a set of points, remove the small nut and bolt which secure the wiring to the breaker point set; remove the adjustment screw, and take off the old set of points.

2. When installing the new points, be sure that the fiber insulating washers are correctly located.

6. Point breaker cam
7. Timing plate
8. Oil seal
9. Camshaft inner bearing
10. Circlip
11. Camshaft outer bearing
12. Camshaft

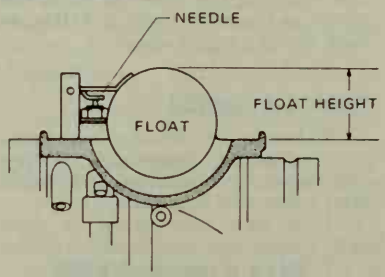
Adjusting the point gap

1. Remove the points cover and the spark plugs.
2. Clean and gap each of the points as described above.

NOTE: *For each model, the timing of the LEFT cylinder must be set first. Note that the left cylinder's contact breaker is mounted directly on the points assembly base plate. The entire base plate is moved to adjust the timing of this cylinder, and this, quite naturally, will affect the timing of the other two cylinders.*

3. Fit the dial gauge into the left cylinder's spark plug hole, then turn the engine over until the dial gauge needle peaks and begins to reverse direction.
4. Turn the engine back and forth until the dial gauge indicates that the piston has reached its highest point of travel. Let the piston stay in this position (TDC), then zero the gauge.
5. Hook up your timing tester. Attach one lead to ground on the engine case, and the other to the movable point terminal for the left cylinder. Note that "L" is stamped adjacent to the left cylinder's breaker points for identification.
6. Refer to the "Tune-Up Specifications" chart at the end of this section for the correct timing settings for your model.
7. Turn the engine backward until the dial gauge indicates that the piston has moved the correct distance below TDC.
8. At this point, your tester should indicate that the points have just opened. If they have not, loosen the 3 screws which secure the breaker base plate, and turn the plate in the direction necessary so that the points are just beginning to open with the piston in the position above.
9. After tightening the breaker base plate screws, recheck the left cylinder's timing.
10. Move the dial gauge to the right cylinder, and connect the tester to the points for the right cylinder (indicated by the "R" stamped on the base plate). Repeat the procedure, as above, for checking the timing.

If adjustment is needed, loosen the two screws which secure the contact breaker mounting plate to the base plate and move the mounting plate as needed to get the points to open at the correct point.



11. Repeat the procedure for the center ("C") points.

CAUTION: *Note that the piston position specifications for the center cylinder of certain models is NOT the same as for the left and right cylinders.*

If an emergency situation arises, the timing can be approximately set using the marks on the timing rotor to set the piston position for each cylinder. For example, the left cylinder's points should just open when the timing mark "L" on the timing rotor is aligned with the line on the casing. As described above, the left cylinder must be set first, then the right and center. Note that this can only be considered an approximate setting. The dial gauge and timing tester method is the recommended procedure.

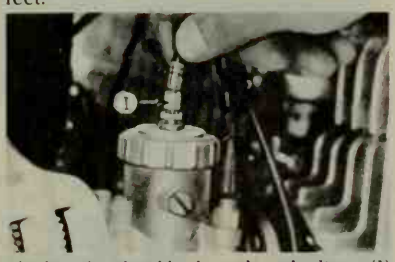
CARBURETOR ADJUSTMENTS

Float Level

Carburetor float height measurement

To adjust the float level on these carbs, first remove the carburetor float bowl and float. Make sure that there's no gas inside the float due to a pinhole leak, then refit the float and, holding the carburetor upside down, lower the float gradually until the float tongue just touches the upper end of the needle. Now, measure the distance between the float bowl gasket fitting surface and the bottom of the float (gasket removed).

If the distance is less than specified, the fuel level is too high; if more than specified, too low. To adjust, bend the float tang only, never the mounting pivot.



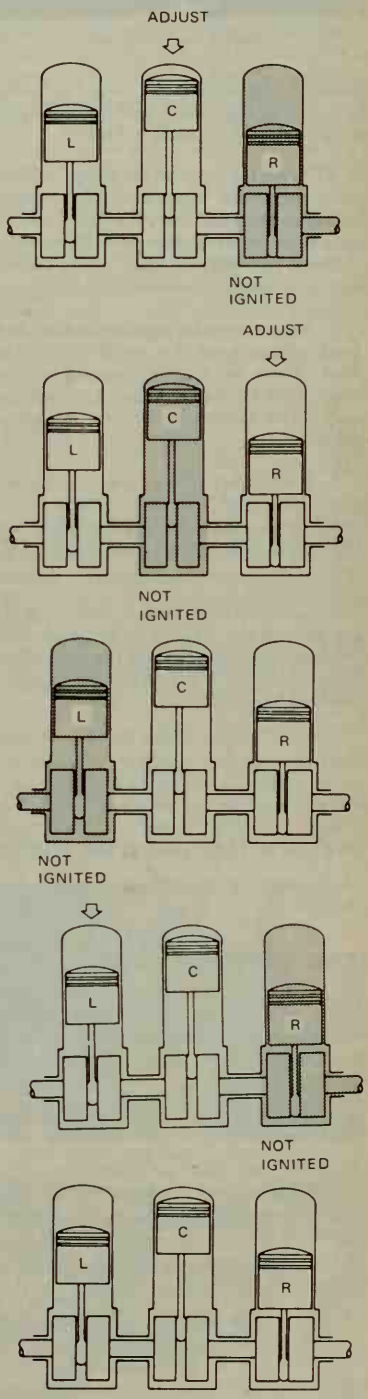
Refer to the "Tune-Up Specifications" chart at the end of this section for the correct float level for your machine.

Idle Speed and Mixture Adjustment

"J" AND "K" MODELS

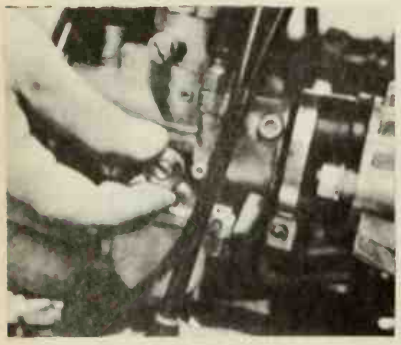
Start the engine and bring it to operating temperature before setting the idle speed.

Be sure that the ignition timing is correct.



Checking throttle cable play at the carb adjuster (1)

If possible, replace the standard spark plugs with ones of a slightly hotter heat range while setting the idle speed.



1. After setting the cable free-play with the carburetor cap adjusters (see "Maintenance") screw each of the pilot air adjustment screws in until it is *lightly* seated, then back it out the specified number of turns:

GT380, GT550 1¼ turns out
GT750 1½ turns out

2. Screw in each of the throttle stop screws until lightly seated, then back each of them out an equal amount (about 3½ turns).
3. Refer to the accompanying illustration to clarify the procedure. Basically, it

Five steps for adjusting the idle speed and mixture

Adjusting the idle speed

involves disconnecting one cylinder, then setting the idle speed on one of the two remaining running cylinders.

a. With the engine running, disconnect the spark plug lead of the right cylinder, and set the idle speed of the two running cylinders to 1100 rpm by turning the throttle stop screw of the *center* cylinder carburetor only.

b. Reconnect the right cylinder plug lead, disconnect the center cylinder lead. Then set the idle speed to the same rpm as above, using the throttle stop screw for the right cylinder carburetor *only*.

c. Reconnect the center cylinder spark plug lead; disconnect the left cylinder lead. Note the rpm reading on the tachometer. Call this value "X" rpm.

d. Connect the left cylinder lead; disconnect the right cylinder lead. Use the throttle stop screw of the left cylinder carburetor to adjust the tachometer reading to "X" rpm.

e. Now connect the right cylinder lead so that the machine is firing on three cylinders. Turn each of the throttle stop screws out an equal amount to bring the idle speed to 1000 rpm (GT750) or 1100 rpm (GT380, GT550).

4. Proceed to throttle slide synchronization.

GT380, GT550 "L-A" MODELS

1. Make the adjustments when the engine is at operating temperature. Be sure that all items in the ignition systems (plugs, points, etc.) have been correctly set.

2. Adjust throttle cable free-play (see "Maintenance").

3. Turn each pilot air screw in until it is seated, then back each out the number of turns shown in the "Tune-Up Specifications" chart.

4. Using the idle speed wheel, set idle at 1500 rpm.

5. Refer to the illustration "Five steps for adjusting the idle speed and mixture." The procedure for L-A models is essentially the same as for J-K models outlined above.

a. Disconnect the right cylinder's spark plug cap, and adjust the throttle slide adjustment nut on the center cylinder so the engine will run at 1000 rpm.

b. Reconnect the right cylinder; disconnect the center cylinder's plug lead and use the right cylinder's slide adjustment nut to set idle at 1000 rpm as before.

c. Connect the center cylinder. Disconnect the left cylinder's plug lead and note engine rpm.

d. Connect the left cylinder's lead. Disconnect the right cylinder's lead. Note engine rpm. Use the throttle slide adjustment nut of the left cylinder to adjust idle speed to the same value obtained in Step "c."

e. With all cylinders connected, rev the engine a few times to clean the plugs, and set idle speed to 1100 rpm with the idle speed wheel.

GT750 "L-A" MODELS

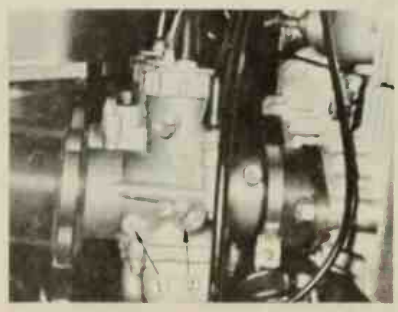
1. Make adjustments when the engine is at operating temperature. Adjust points, plugs, ignition timing and throttle cables before this procedure.

2. Turn each pilot screw in until lightly seated, then back each out ¼ turn for GT750L or ¾ turns for FT750M-A.

3. Turn the idle speed screw to achieve an idle speed of 3000 rpm.

4. Disconnect the left and center spark plug caps. Adjust the idle speed screw so that the engine idles at 1000 rpm.

5. Connect the lead for the center cylinder; disconnect the lead for the right cylinder. Adjust the center cylinder's throttle stop screw to obtain an idle of 1000 rpm.



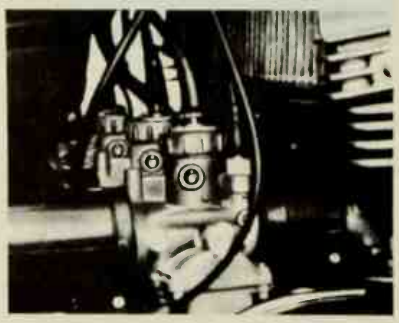
6. Connect the lead for the left cylinder. Disconnect the lead for the center cylinder. Adjust the left cylinder's throttle stop screw to obtain an idle speed of 1000 rpm.

7. Connect all three leads, rev the engine a few times to clean off the plugs; set idle speed to 1000 rpm using the idle speed screw.

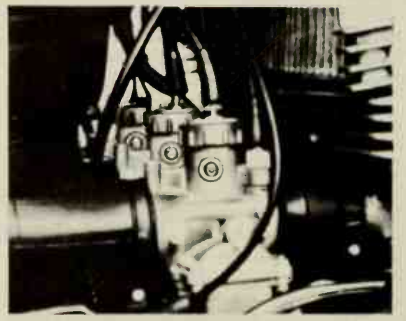
Throttle Slide Synchronization

"J" AND "K" MODELS

1. Accomplish the setting of the cable adjusters and the idle speed and mixture as described above.



SC-series carburetor pilot air screw (1) and throttle stop screw (2)



2. Remove the carburetor alignment hole plugs.

3. Turn the twist-grip about half-open, so that the punch marks on the carburetor slides are aligned with the upper surface of the alignment hole.

4. Use the cable adjusters on each carburetor cap to bring the slides into alignment. Refer to the illustration of the correct slide alignment.

Correct throttle slide alignment

Incorrect throttle slide adjustment

5. Replace the alignment hole plugs.

6. Set the throttle cable adjuster near the twist-grip to give the following cable free-play:

GT380, GT550	1–2 mm	(0.04–0.08 in.)
GT750	0.5–1.0 mm	(0.02–0.04 in.)

7. After all adjustments have been made, start the engine, and turn the handlebars lock-to-lock and note any variation in engine speed. This would indicate that the cable was adjusted too tightly, or that the throttle cable is binding or being pinched somewhere along its route.

NOTE: *After throttle cable adjustments, always check the oil pump cable adjustment. Refer to "Maintenance."*

"L-A" MODELS

Because of the pulley and linkage used, slide synchronization is not usually necessary unless the linkage has been disassembled. In any event, removal of the carburetors and linkage is necessary. Refer to "Fuel System" for procedures.

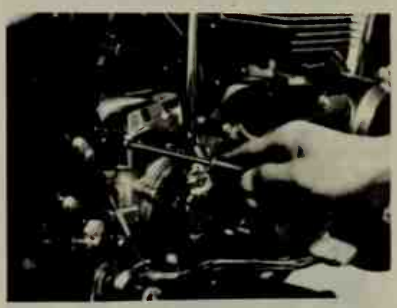
NOTE: *For engine component inspection techniques and procedures, refer to "Engine Rebuilding" under the General Information section.*

ENGINE SERVICE



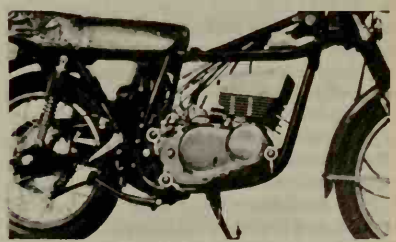
Removal

GT380

1. Clean the engine thoroughly before removal.
2. Shut off the fuel petcock, and disconnect the fuel lines at the petcock.
3. Free the gas tank from its mounts, lifting it up at the rear and removing it from the machine.
4. Disconnect the 3 spark plug wires from the spark plugs.
5. Disconnect the alternator wires at the plastic couplers beneath the left side cover.
6. Disconnect the contact breaker point wires at the coupler.
7. Disconnect the oil line at the bottom of the oil tank, catching the oil in a container, or plugging the hole. Remove the drain plug for the transmission oil at the bottom of the crankcase, and allow the oil to drain for several moments.
8. Loosen the clamps which secure the left-side carburetor to the manifold and to the air cleaner, and pull the carburetor free, placing it carefully out of the way. The carburetors are located by a pin on the manifold. Do not twist or tilt the unit while removing.
9. Loosen the clamps which secure the center and right-side carbs to the air cleaner, then remove the air cleaner from the machine.
10. Loosen the clamps securing the center and right carburetors to the manifold, and pull off the carbs.

On 1974 and later models, disconnect the throttle cables and remove the carbs together after loosening the clamp screws and removing the air cleaner.

11. Remove the oil pump cover just beneath the right carb; disconnect the oil pump cable.
12. Disconnect the tachometer cable at the engine. Remove the rear brake light switch from its bracket.



Removing the oil pump cover

13. Remove the right-side rider's footpeg; pull off the rear brake pedal.
14. Remove the nuts which secure the exhaust pipe clamps to the cylinders, then remove the passenger footpegs. Remove the right and left exhaust pipes and mufflers. Loosen the clamps securing the center mufflers to the exhaust pipe, and pull the mufflers back until they are free of the pipe. Then remove the pipe.
15. Remove the left rider's footpeg, then loosen the pinch-bolt and pull the gearshift lever off the splined shaft.
16. Remove the clutch adjuster cover (left-side).
17. Remove the countershaft sprocket cover. Remove the 3 bolts, and remove the countershaft sprocket from the shaft. Move the chain out of the way so that it will not interfere with the engine removal.
18. Remove the Ram Air cover.
19. Remove all of the engine mounting nuts and bolts, take out the rear engine mounting plates, and take the engine out of the frame.

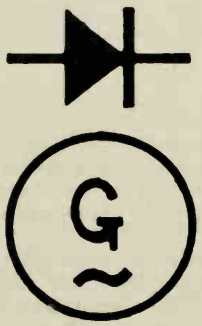
GT550

1. Clean the engine thoroughly prior to removal.

2. Shut the fuel petcock off, and disconnect the fuel line at the petcock. Remove the rubber strap securing the back of the gas tank, and lift up the back of the tank and remove it from the machine.

3. Disconnect the negative lead of the battery at the battery terminal.



4. Remove the 3 spark plug caps from the plugs. Disconnect the contact breaker wires at the plastic coupler beneath the right side cover.

5. Remove the rear brake light switch from its bracket. Then remove the brake pedal after removing the right footpeg and loosening the rear brake cable.

6. Disconnect the tachometer cable at the engine.

7. Disconnect the starter motor lead at the solenoid located beneath the left side cover.

8. Disconnect the alternator wires at the plastic couplers beneath the left side cover. Note that the alternator coupler and the rectifier coupler are similar in appearance, but have different markings. Be certain that they are properly connected upon reassembly.

Rectifier (top) and alternator coupler designations

9. Remove the oil pump cover, then disconnect the cable from the pump lever and from the engine.

10. Remove the oil line at the tank. Either catch the oil in a container, or plug the hole in the tank with a rubber plug (an inner tube valve cap should work).

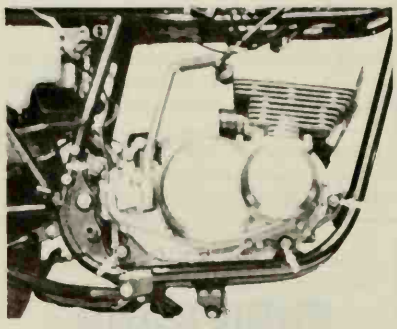
11. Drain off the transmission oil.

12. Loosen the clamps which secure the air cleaner to the carburetors and remove the air cleaner ("J" and "K" models).

13. Loosen the clamps securing the carbs to the manifold, and remove them. Pull the carburetors straight off the manifold. Do not attempt to twist or turn them as they are located by a pin on the manifold.

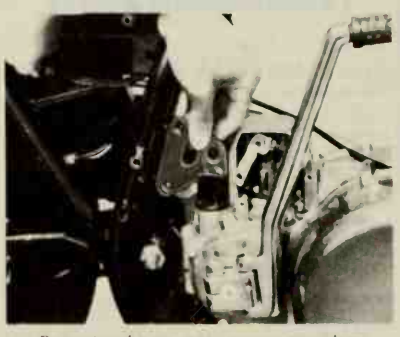
NOTE: *On 1974–76 models which use a pulley and linkage assembly to open and close the carburetor slides, the throttle cables must be disconnected, and the carburetors taken out together.*

14. Remove the left-side rider's footpeg. Loosen the pinch-bolt and remove the gearshift lever from the splined shaft.



15. Remove the clutch mechanism cover, and then the countershaft sprocket cover.

16. Remove the 3 bolts which secure the countershaft sprocket to the shaft, then turn the locking plate half a pitch of the splines until it can be removed from the shaft. Remove the sprocket by pulling it off. Arrange the chain so that it will not interfere with the engine removal.



17. Remove the Ram Air cover.

18. Remove the nuts which secure the exhaust pipe clamps to the cylinder. Remove the passenger footpegs. Take off the right and left mufflers and exhaust pipes.

19. Loosen the clamps which secure the center mufflers to the center exhaust pipe, and pull the mufflers back and free from the pipe. Remove the exhaust pipe from the machine.

Removing the rear engine mounting plate

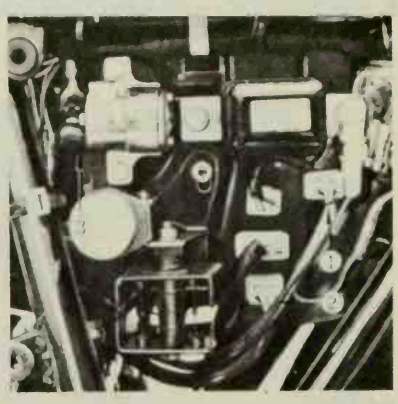
20. Remove all of the engine mounting nuts and bolts, the rear engine mounting plates, and remove the engine from the right-side of the frame.

GT750

1. Drain the cooling system by loosening the water drain plug at the front, center, of the engine. Drain the transmission oil.

Water drain plug location

Disconnect the oil feed line at the oil tank and either drain the oil or plug the tank.



2. Disconnect the starter motor lead from the battery terminal.

3. Shut off the fuel petcock, disconnect the fuel lines at the petcock, and remove the gas tank by detaching the rubber strap from the rear of the tank and sliding the tank back and up from the frame mounts.

4. Disconnect the radiator inlet hose, and remove the fan assembly and bracket.

5. Remove the passenger footpegs, loosen the muffler clamp screws, and remove the exhaust pipe bolts on the cylinder head. Remove the exhaust system.

6. Remove the left side cover, which will expose the electrical connections. Refer to the accompanying illustration. Disconnect the alternator (1), contact breaker (2), and starter motor (3) leads, and then disconnect the ground wire from the frame.

Alternator (1), contact breaker (2), and starter motor (3) leads

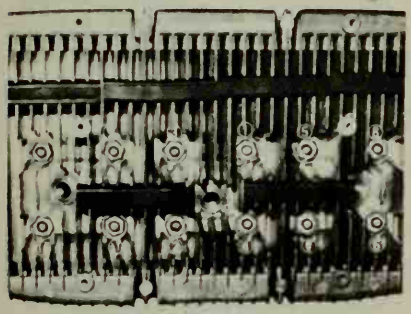
7. Remove the air cleaner by removing the set bolts on top and the 3 carburetor clamp screws.

8. Remove the left-side footpeg, the shift lever, and the countershaft sprocket cover. Bend down the locktab on the countershaft sprocket nut, remove the nut, and pull off the sprocket. It is not necessary to disconnect the chain. Arrange the chain out of the way so that it does not interfere with the engine removal.

9. Disconnect the clutch, oil pump, and tachometer cables at the engine. Disconnect the carburetor cables and remove the carburetors.

10. Remove the right-side footpeg and the rear brake pedal.

11. Remove the engine mounting nuts and bolts, the mounting plates, and take the engine out of the frame.



Installation

ALL MODELS

To install the engine, reverse the removal procedure. It is important that all important nuts and bolts be properly tightened. Torque specifications are given at the end of this section. The joints of the exhaust pipe coupler tubes

should be coated with a temperature-resistant sealant before reassembly.

New exhaust pipe gaskets (at the cylinders) should be used. Leave a gap of 1 mm (0.04 in.) between the cylinder and the exhaust pipe clamp when installing the exhaust system.

Cylinder head nut loosening order (GT380, GT550)

TOP END

GT380, GT550

It is possible to remove the head and barrels with the engine still in the frame. To do this, remove the gas tank, disconnect the spark plug leads; remove the Ram Air scoop, the carburetors, and exhaust system.

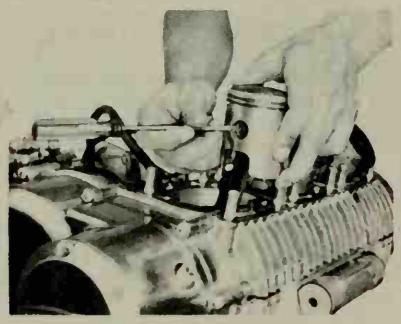
REMOVAL

1. The cylinder head is a one-piece casting and is secured to the cylinders by 12 thru-studs which are anchored in the barrels.

2. Refer to the illustration for cylinder head nut loosening order. Loosen each nut about ¼ turn at a time until they are free of tension, then remove them completely.

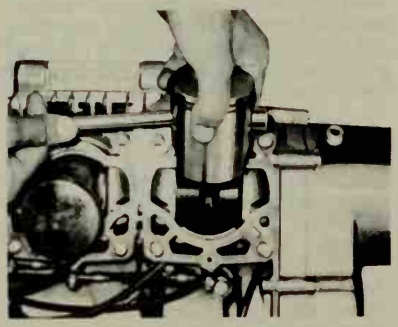
3. Lift the head clear of the studs and remove it. Remove the head gaskets. If the head resists removal, tap lightly all around the head-barrels joint with a soft-faced mallet to free it.

4. The 3 cylinders are separate, and each is secured to the crankcase by 4 nuts on studs which are anchored in the case. Each cylinder is removed separately.



5. Pull out the SRIS hoses on the intake side of the cylinders. Loosen the nuts for either outside cylinder gradually in a cross pattern, then remove the nuts and the washers beneath them. Pull off the cylinder, tapping gently on the underside of the fins to free it from the case as necessary.

6. Remove the cylinder base gaskets.



7. Pistons must be reinstalled into their proper cylinder; therefore, mark the position of each piston before removal. Stuff a clean, lint-free rag into the crankcase under the pistons. To remove the pistons, pry out the wrist pin circlips with a small screwdriver or needlenose pliers.

The wrist pin can then be pushed out with a suitable sized drift. Discard the circlips. New ones must be used upon assembly.

8. If, for some reason, the wrist pin will not yield to the normal method of

Removing a piston wrist pin circlip

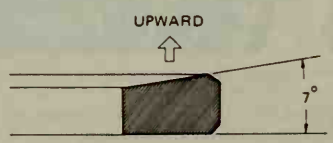
Removing a wrist pin

removal, low heat may be applied to the piston crown to aid removal. Take care that only the crown is heated, and that sparingly.

INSPECTION

1. Check the head for warpage.

Note that *each cylinder's* mating surface must be checked as well as the overall head warpage. Observe the following tolerances:



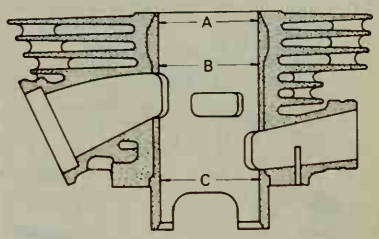
a. No individual mating surface may be warped more than 0.03 mm (0.0012 in.).

b. No individual mating surface may be more than 0.1 mm (0.004 in.) below the line of the others.

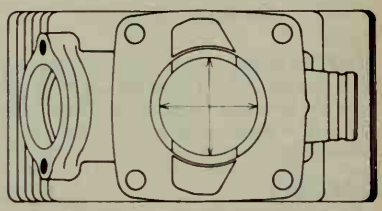
c. Total warpage of the head must not exceed 0.15 mm (0.006 in.).

2. On the GT380, the top piston ring is wedge shaped, the upper surface of the ring being inclined 7° above the horizontal.

The lower ring on the GT380 is flat.



Correct installation of the wedge-shaped piston ring

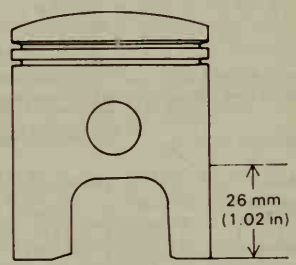


On the GT550, both rings are wedge shaped. Needless to say, the rings on the GT380 are not interchangeable, and the wedged ring must always be installed in the top ring groove.

On all rings, a letter stamped on the top indicates the side which must face UPWARD.

3. Standard ring end-gap is 0.15–0.35 mm (0.006–0.014 in.). Rings must be replaced if end-gap exceeds:

GT380—1.0 mm (0.04 in.)
GT550—0.7 mm (0.028 in.)



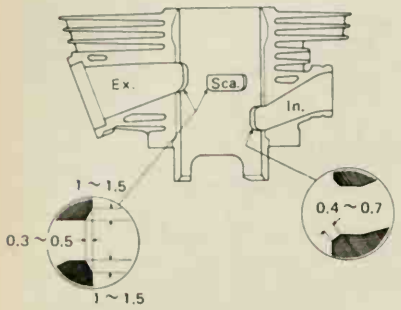
Cylinder bore measurement points (A, B, and C)

4. The cylinder bores should be checked for both taper and ellipticity. Measure the diameter of the bore at the top, middle, and bottom keeping the micrometer in the same plane; the readings should be taken at 6 mm (0.24 in.) below the top of the cylinder; 5 mm (0.20 in.) above the exhaust port; and 5 mm (0.20 in.) below the intake port.

Then take another set of readings at the same positions on the cylinder, but 90° from the first set.

If the difference between the largest and smallest of the six readings exceeds 0.1 mm (0.004 in.), the cylinders must be rebored to the next oversize, and then honed.

Oversized pistons are available in diameters 0.5 mm and 1.0 mm greater than standard.

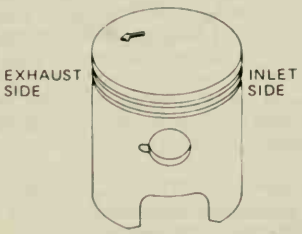


Piston diameter measurement point

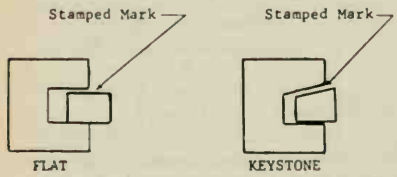
5. Piston-to-cylinder clearance (standard) is 0.045 mm (0.0018 in.). Determine the clearance by measuring the diameter of the cylinder bore at a point 20 mm (0.79 in.) below the top of the cylinder, measuring from back to front of the cylinder.

Measure the diameter of the piston at a point 26 mm (1.02 in.) above the bottom ton wrist pin. Maximum acceptable piston-to-cylinder clearance (used) is 0.1 mm (0.004 in.). After this, the cylinders must be bored to fit oversized pistons.

NOTE: *After boring the cylinder, the edges of the ports must be chamfered according to the dimensions shown in the illustration.*

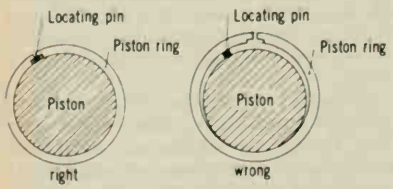


Port chamfer dimensions

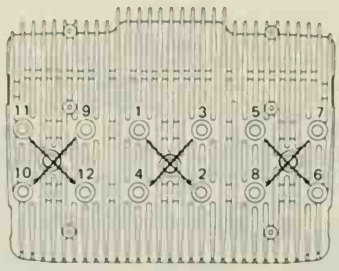


NOTE: *Even if the cylinder has not been bored, check that the edges of the ports are not sharp. If they are, chamfer them with emery cloth or a small file.*

ASSEMBLY

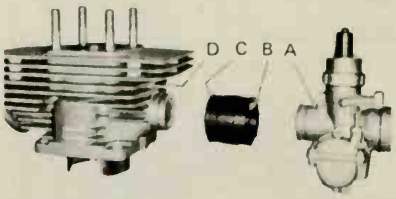


1. Be sure that the rings are correctly installed on the pistons, with the lettered side of the ring facing up. Note that the wedge shaped ring of the GT380 is installed in the uppermost ring groove.
2. Install each piston on its own connecting rod, making certain that the arrow stamped on the piston crown points toward the EXHAUST port. Use new wrist pin circlips when refitting the pistons. Install the wrist pins using firm, steady pressure as on removal.
3. Use new cylinder base and cylinder head gaskets.

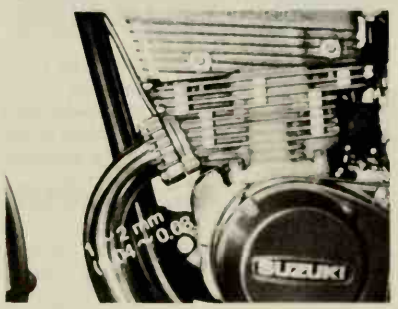


The arrow on the piston crown must point toward the exhaust port when the piston is installed

The stamped side of the piston ring is installed facing up



Correct and incorrect installation of the rings



Cylinder head nut tightening order

4. Arrange the rings so that the ring ends are aligned with the locating pin in each ring groove. This is most important.
5. Lubricate the connecting rod small end, the rings, and the cylinder walls before installing the cylinders. Use CCI oil.
6. Slide each cylinder down over the piston while compressing the piston rings with your fingers. When the cylinder is seated on the crankcase, tighten the cylinder nuts gradually and in an "x" pattern.
7. Refit the cylinder heads and tighten the nuts gradually and in the pattern shown until the proper torque (18–29 ft lbs) is reached.
8. Refer to the accompanying illustration when installing the rubber intake manifold. Note that the notch "C" on the manifold must engage the rib on the cylinder "D" which will allow proper installation of the carburetors.
9. When installing the exhaust pipes, allow 1–2 mm (0.04–0.08 in.) clearance between the cylinder and the exhaust pipe clamp.

Locating pins and slots insure correct carburetor alignment

GT750

REMOVAL

1. It is possible to remove the cylinder head and block without removing the engine from the frame. Loosen the water drain plug at the front, center, of the engine to drain the cooling system. Remove the gas tank, disconnect the radiator inlet hose and remove it; loosen the water by-pass hose clamp; disconnect the spark plug caps; remove the exhaust pipes; remove the carburetors.
2. Loosen the cylinder head nuts and bolts gradually (about ¼ turn at a time) in the order shown. When there is no longer any tension on the nuts and bolts, remove them all and take off the cylinder head. Remove the head gasket.

Cylinder head nut and bolt loosening order

SRIS hose arrangements

3. Remove the SRIS lines from the cylinder. Remove the cylinder set nut behind the right cylinder. Lift the cylinder up and free of the pistons.

CAUTION: *Do not allow the pistons to strike the cylinder studs when they drop free of the cylinder.*

4. Remove the cylinder base gasket.
5. Pistons must be reinstalled into their proper cylinder; therefore, mark the position of each piston before removal. Stuff a clean, lint-free rag into the crankcase under the pistons. To remove the pistons, pry out the wrist pin circlips with a small screwdriver or needlenose pliers.

The wrist pin can then be pushed out. Discard the circlips; new ones must be used upon assembly.

6. If, for some reason, the wrist pin will not yield to the normal method of removal, low heat may be applied to the piston crown to aid removal. Take care that only the crown is heated, and that sparingly.

Be sure that each wrist pin is installed with its own piston upon reassembly.

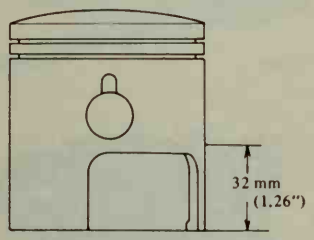
INSPECTION

1. Check the head for warpage. Warpage exceeding 0.04 mm (0.001 in.) must be remedied.
2. Wrist pin play in the rod small end should not exceed 0.05 mm (0.002 in.).
3. Note that both rings on the GT750 pistons are wedge-shaped.

Maximum allowable ring end-gap is 0.7 mm (0.027 in.). Replace the rings if the end-gap exceeds this figure.

Standard ring end-gap is 0.15–0.35 mm (0.006–0.014 in.).

4. Piston ring side-clearance should be 0.030–0.095 mm (0.001–0.004 in.). If side-clearance is excessive, replace the rings.

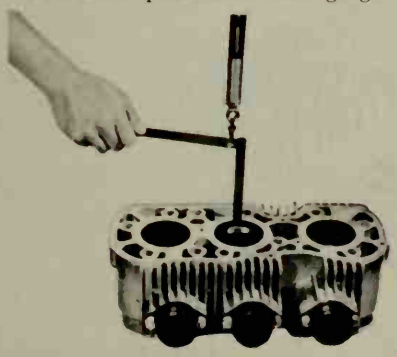


5. Refer to GT380, GT550 "Inspection" for bore measurement points.

Although the procedures are similar for the GT750, specifications are different. Note the following:

a. If the difference between the largest and smallest of the six cylinder bore measurements exceeds 0.07 mm (0.0028 in.), bore and then hone the cylinders.

b. Standard cylinder bore is 70.000–70.015 mm (2.7559–2.7565 in.). If any of the readings exceed this measurement by more than 0.07 mm (0.0018 in.), the cylinders must be bored.

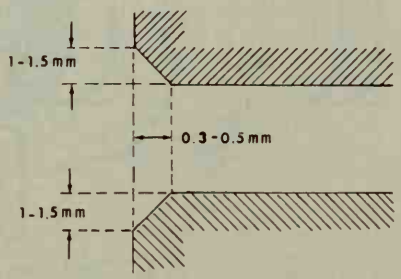


c. Standard piston diameter is 69.950–69.965 mm (2.7539–2.7545 in.). Piston diameter is measured at a point 32 mm (1.26 in.) above the bottom edge of the skirt and perpendicular to the piston wrist pin.

Piston diameter measurement point

d. Standard piston-to-cylinder clearance is 0.045–0.055 mm (0.0018–0.0022 in.) and may be determined by subtracting the diameter of the piston from the largest of the cylinder bore measurements obtained. Maximum allowable clearance is 0.07 mm (0.0028 in.).

e. Another method of checking the clearance is to insert a feeler gauge of the proper thickness into the bore, and then insert the piston. Using a spring scale, pull out the feeler gauge. Between 2.2–4.4 lbs (1–2 kg) should be sufficient to pull out the feeler gauge.

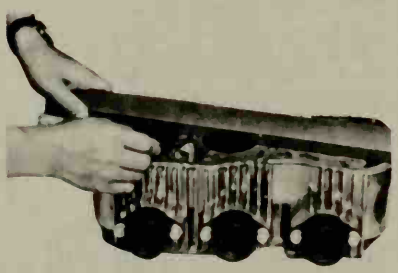


Checking piston-to-cylinder clearance with a feeler gauge and spring scale

f. Oversized pistons are available in two sizes: 0.5 and 1.0 mm. These pistons have the following diameters:

1st oversize (0.5 mm):	70.450–70.465 mm (2.7736–2.7742 in.)
2nd oversize (1.0 mm):	70.950–70.965 mm (2.7933–2.7939 in.)

Note that when reboring the cylinders, the dimension of the bore will be determined by the diameter of the pistons to be used plus the specified clearance.



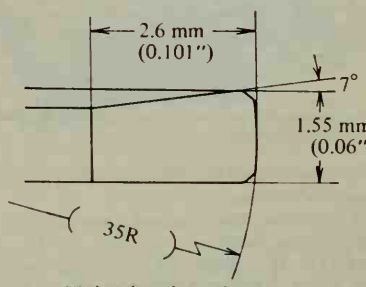
g. Whenever the cylinders are bored, they must be honed as well. Also, it is necessary to chamfer the edges of the ports whenever boring is accomplished. The ports should be chamfered to the dimensions shown in the accompanying illustration.

Port chamfer dimensions

h. If piston-to-cylinder clearance exceeds 0.07 mm (0.0028 in.) and the bore does not show excessive taper or wear, it may be possible to bring the clearance within tolerance by replacing the piston. The cylinder will still have to be honed, however.

6. Check the cylinder block top surface for warpage with a straightedge (as shown), or by placing the block, upside down, on a known flat surface. Determine the degree of warpage by probing around the mating surface with a feeler gauge. If the warpage exceeds 0.05 mm (0.002 in.), the mating surface must be lapped, or the block replaced.

Checking the cylinders for warpage



7. If the proper equipment is available, the block should be checked with air pressure for tightness. No leakage should be detected at a pressure of 3 kg/cm² (42.6 psi).

ASSEMBLY

NOTE: *Pistons must be installed in their original locations. If new pistons are fitted, note that the crown is stamped with either an "R" or "L." "R" pistons are always installed in the right cylinder, while "L" pistons are installed in the left and the center cylinders.*

1. Be sure that the piston rings are correctly installed, lettered side UP. If old rings are used, be sure that they are installed in their former location on the piston they came from.

2. Install each piston on its connecting rod, making certain that the arrow

Wedge-shaped ring dimensions

stamped on the piston crown points toward the EXHAUST port. Use new wrist pin circlips when refitting the pistons.

3. Replace the 3 water passage O-rings at the front (top) of the crankcase with new ones. Fit a new cylinder base gasket.

4. Arrange the piston rings so that the ring ends are aligned with the locating pin in each ring groove. This is very important.

5. Lubricate the connecting rod small end, the rings, and the cylinder walls before installing the cylinder block. Use CCI oil.

6. Piston ring compressors should be used to hold the rings in while the block is fitted over the studs and slipped down over the pistons.

7. Replace and tighten the cylinder set nut.

8. Refit the cylinder head, and tighten the nuts and bolts in the order given for loosening. The nuts and bolts should be tightened in small increments until the proper torque is reached:

8 mm nuts and bolts—13.0–15.9 ft lbs.
10 mm bolts—21.7–29.0 ft lbs.

9. Reconnect the SRIS lines to their fittings on the block.

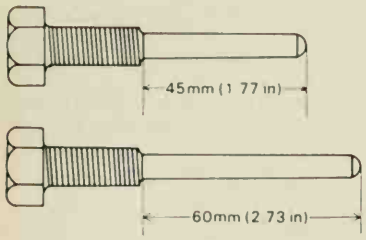
10. Continue assembly in the reverse of the disassembly procedure.

CRANKCASE COVER ASSEMBLIES

On all three models, the crankcase covers contain the clutch, alternator, and breaker point assemblies.

NOTE: *On all models, removing the alternator requires the use of special tools.*

GT380



LEFT CRANKCASE COVER AND ALTERNATOR

Removal

1. Remove the left footpeg. Remove the gearshift lever pinch-bolt and (carefully) pull the lever off the splined shaft.

2. Remove the clutch adjuster cover screws and remove the cover.

3. Remove the alternator cover screws, and take off the cover. Note that this cover is fitted with a gasket.

Two types of rotor puller: 45 mm length (top) for the Kokusan and 60 mm for the Denso rotors

4. Disconnect the Neutral switch wire from the switch.

5. Remove the 3 stator screws, then take off the stator.

NOTE: *If a Nippon Denso alternator is fitted, lift the carbon brush off the slip-ring by hand while removing the stator.*

6. Two types of alternator are fitted, therefore a different rotor puller is needed depending on which type you are working with.

The Nippon Denso alternator requires a puller with a 60 mm (2.36 in.) unthreaded portion.

The Kokusan Denki alternator requires a puller with a 45 mm (1.77 in.) unthreaded portion.

7. If the engine has been removed from the frame, or the cylinders removed, lock the crankshaft in place with the special tool (No. 09910–20113) placed under the piston.

If the engine is still in the frame, and the cylinders have not been removed, place the transmission in First gear, and have an assistant apply the rear brake while removing the rotor.

8. Remove the rotor bolt, then use the special tool and remove the rotor itself. To remove the rotor, tighten the puller to 6.6–10 ft lbs.

9. To gain access to the countershaft sprocket, remove the sprocket cover after disengaging the clutch cable from the clutch release mechanism, and unscrewing the cable adjuster from the sprocket cover. The sprocket cover is secured by 4 screws.

Inspection

1. All electrical tests are given in the "Electrical Systems" section.

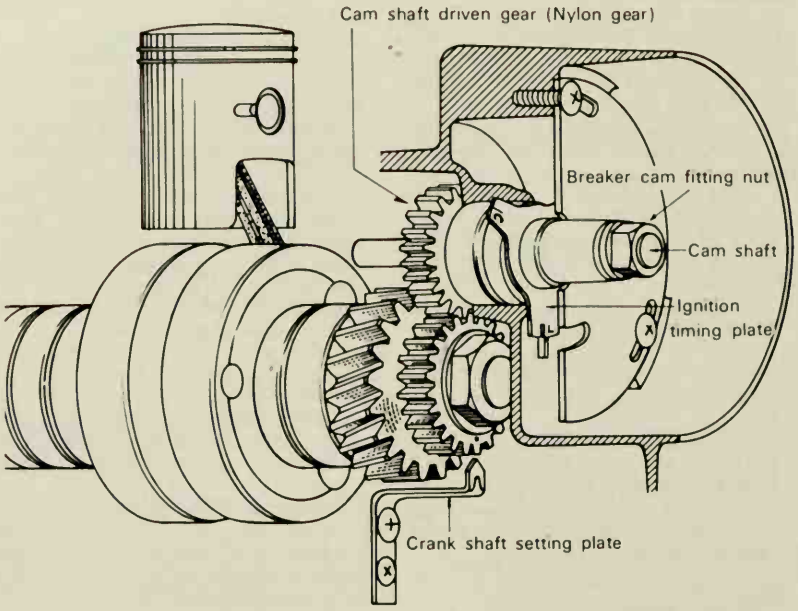
2. Check that the rotor does not have scoring or wear marks on it, as it might if it has contacted the stator.

Assembly

1. Reverse the removal procedure.

2. When refitting the stator, take care that the carbon brush (if fitted) is held out of the way while the stator is positioned.

3. Make sure that the stator and rotor are separated by an even air gap all the way around. Move the stator on its mounting screws as necessary to achieve this.



4. If the rotor and stator touch at any point, one of them is not mounted correctly.

5. Tighten the rotor bolt to 6.6–10 ft lbs.

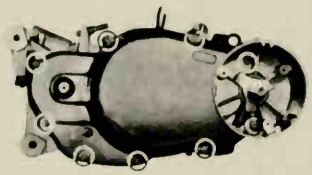
RIGHT CRANKCASE COVER COMPONENTS

The right crankcase cover contains the breaker point assembly, and removing the cover will reveal the clutch assembly and the crank and kickstarter drive gears.

A special tool is sometimes necessary to remove the clutch hub. It must be held stationary while the hub nut is removed.

Breaker cam drive (GT380)

Removal and Disassembly

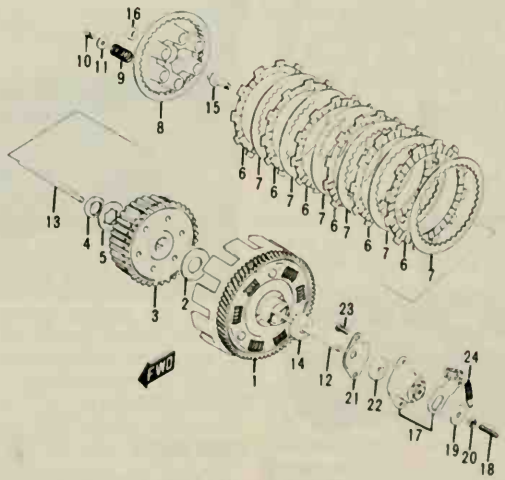


1. Drain the transmission oil.

2. Remove the right-side footpeg.

3. Remove the breaker points inspection cap.

4. Disconnect the points wires, remove the 3 base plate screws, and remove the contact breaker assembly.



5. Remove the kickstarter pinch-bolt, and pull the kickstarter off the splined shaft.

Right crankcase cover screws (GT380)

6. Remove the right crankcase cover securing screws. There are 9 of them; note that two are found inside the points compartment.

CAUTION: *It is not necessary to remove the breaker cam nut to remove the right case cover. To attempt to do*

8. To remove the clutch assembly, loosen the six clutch spring bolts on the clutch pressure plate a bit at a time in a cross pattern, then remove the bolts, washers and springs.

9. Remove the pressure plate, push crown, pushrod, then remove all of the metal and fiber plates from the clutch housing.

10. Use a punch to bend down the

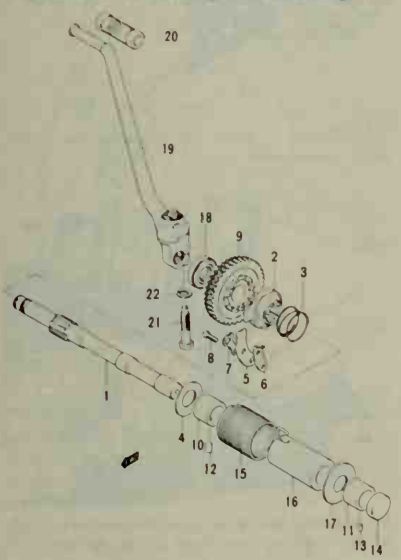
clutch hub nut lockwasher. Then remove the nut.

11. Take off the clutch hub, thrust washer, and housing.



12. Take off the kickstarter gear, the ratchet wheel, and the spring.

13. To remove the crankshaft gears, first remove the crankshaft setting plate. Bend down the tab on the lockwasher.

14. Use the shop tool or a suitable substitute to lock the right connecting rod into place (so that the crank will not move), then remove the crankshaft gear nut and lockwasher.

15. Pull off the contact breaker drive gear, then the primary pinion. Note that both of these gears are keyed to the crankshaft.

You should be able to remove the gears by hand.

Inspection

1. For clutch specifications refer to the chart at the end of this section.

2. Note that the contact breaker cam is fitted to a shaft which rides on a ball bearing. Since the bearing is not subjected to any real load, it should be free of damage. Turn the shaft noting any excessive noise or any binding of the bearing. There should be no lateral shaft play.

3. The points are driven from the crankshaft by a nylon gear on the end of the shaft. Check this gear for any damage to the teeth or other wear.

4. If it is found necessary to remove the breaker cam assembly, remove the shaft nuts, nylon gear, timing plate, and pull out the shaft. An oil seal is fitted over the bearing. After removing the seal, take off the bearing retaining circlip, and tap out the bearing from the inside of the case.

A new oil seal must be used upon reassembly.

Assembly and Installation

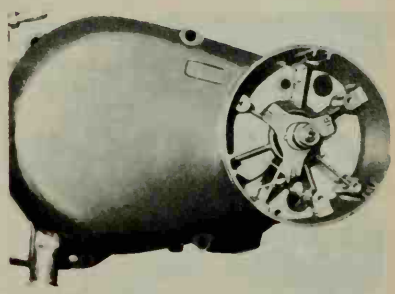
1. Reverse the removal procedure. Note the following points.

2. Install the primary pinion woodruff key, then the pinion. Install the contact breaker drive gear key, then the gear.

Tighten the crankshaft nut to 36 ft lbs. Install the crankshaft setting plate. Secure the plate screws with a thread locking compound.

3. Install the kickstarter mechanism lining up the punch mark on the ratchet wheel with the punch mark on the shaft.

4. Install the clutch assembly. Note the thrust washer between the hub and housing. When installing the plates, fit a steel plate *first*, then alternate friction and steel plates. When tightening the clutch hub nut, hold the housing as on removal. Tighten the nut to 36–43 ft lbs. Bend up the lockwasher tab.



5. Tighten the clutch spring bolts gradually and in a cross pattern to 2.9–5.1 ft lbs.

6. Engine timing marks *must* be properly aligned to accomplish ignition timing. Proceed as follows:

a. Turn the crankshaft so that the punch mark on the contact breaker drive gear is lined up with the mark on the crankshaft setting plate.

b. Line up the scribed line marked "L" on the 3-pronged timing rotor with the mark on the crankcase cover.

c. Match the locating pin on the crankcase with the hole in the right crankcase cover, and replace the cover. NOTE: *A new gasket should always be installed. Also be sure to grease the lips of the kickstarter oil seal before installing the cover.*

Timing rotor correctly positioned for case cover installation

7. Refit and tighten the cover screws. Install the breaker plate. Be sure that the wires are correctly positioned so that they are not pinched between the plate and the inside of the cover.

8. Adjust the clutch after assembly is complete.

GT550

LEFT CRANKCASE COVER AND ALTERNATOR

The procedures for removing and installing the right crankcase cover components on the 550 are essentially the same as described for the 380, above. Refer to that Section.

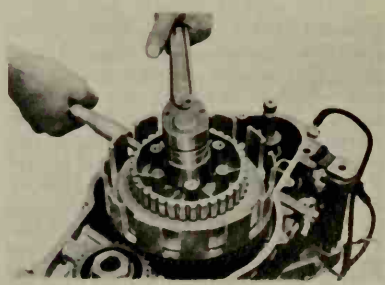
RIGHT CRANKCASE COVER COMPONENTS

Removal

1. Drain the transmission oil if this has not already been done. Remove the right-side footpeg.

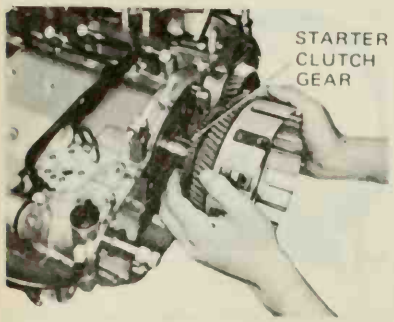
2. Remove the kickstarter lever pinch-bolt and carefully pull the lever off the splined shaft.

3. Remove the right crankcase cover securing screws, and pull off the cover.



NOTE: *It is not necessary to remove the breaker points.*

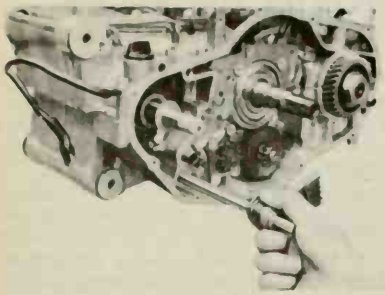
4. Loosen the clutch spring screws gradually and evenly. Then remove the screws, caps, and springs. Take off the pressure plate, the push crown, and the clutch plates.



5. Bend down the tab on the clutch hub nut lockwasher. While holding the clutch with the special tool, loosen and remove the clutch hub nut.

6. Grasping the clutch housing AND the starter clutch gear with your hands, as illustrated, pull the assembly off the clutch shaft.

NOTE: *It is important that the starter clutch gear be taken off along with the clutch housing, or the other starter clutch components may drop off the housing when it is removed.*



Removing the clutch hub nut

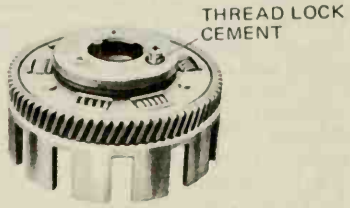
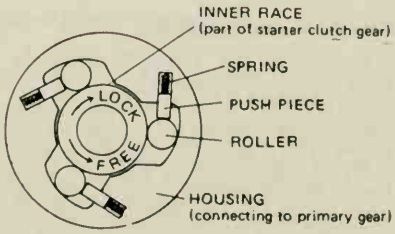
7. Pull out the gear shifter shaft.
8. Remove the oil guide plate. The securing screws will have to be removed with an impact driver. Remove the kick-starter shaft thrust washer. Take off the circlip, washer, spring, and ratchet wheel.

Removing the gearshifter shaft



9. Remove the starter motor cover.
10. Remove the securing screws and take out the starter motor.

Removing the oil guide plate



Inspection

1. For clutch specifications refer to the chart at the end of this section.
2. The contact breaker assembly is mounted in the right side-cover, and is accessible after removing the small cover plate. The breaker cam is mounted on a shaft which is driven by the crankshaft primary gear. The shaft rides on two bearings. Since the bearings are not subject to any real load, they should be free of damage. Turn the shaft noting any excessive noise or binding; check the shaft for lateral play. There should be none.
3. The breaker points compartment is kept free of oil by a seal installed beneath the 3-pronged timing plate rotor. If this seal is removed, it must be replaced. The seal should be replaced, as necessary, at the first sign of oil in the points case.
4. The breaker point shaft bearings are retained by a circlip accessile after removing the oil seal.
5. Check the condition of all gear teeth, noting any chipped or worn teeth.
6. If the crankshaft primary gear is damaged, remove it by bending down the lockwasher, removing the nut, and pulling the gear off the crankshaft. Note that the gear is located by a woodruff key.
7. Disassembly of the starter clutch is not recommended unless the unit is defective.

Starter clutch securing screws

With an impact driver, remove the 3 phillips head screws which secure the starter clutch assembly to the back of the clutch housing. Take off the cover plate. The starter clutch can be inspected in place.

Starter clutch components

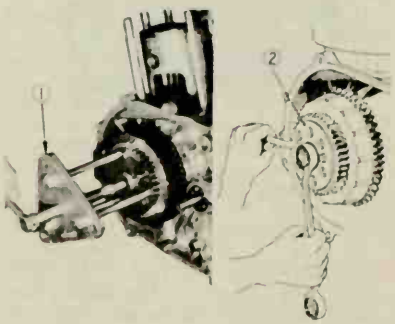
Check the rollers and the housing cutouts for wear or damage. Replace as necessary.

NOTE: *When refitting, be certain that the starter clutch housing screws are secured with thread locking compound and are installed with an impact driver.*

Assembly and Installation

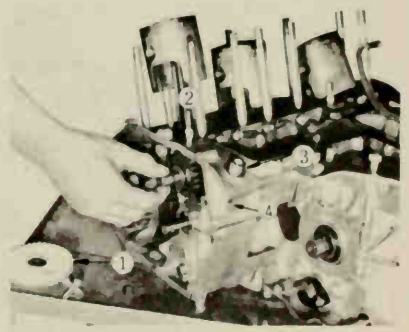
Reverse the disassembly procedure. Note the following:

1. The ratchet wheel punch mark must be aligned with the mark on the kick-starter shaft. Turn the wheel so that the boss rests against the stopper plate.
2. The oil guide plate screws should be secured with an impact driver.
3. Torque the clutch hub nut to 36–43 ft lbs. Bend up the lockwasher tab.
4. Torque the clutch spring screws to 2.9–5.1 ft lbs. They should be tightened gradually and in a cross pattern.
5. When installing the cover, note that the contact breaker cam shaft pin must be properly engaged with the primary gear.
6. Adjust the clutch after assembly is complete.



GT750

LEFT CRANKCASE COVER COMPONENTS



The breaker points are located beneath a cover at the forward, left-side of the engine. Behind the points are the starter clutch assembly, water pump drive gear, electric starter gears, and the tachometer drive gear. The countershaft sprocket is beneath the rear left side-cover.

Removal

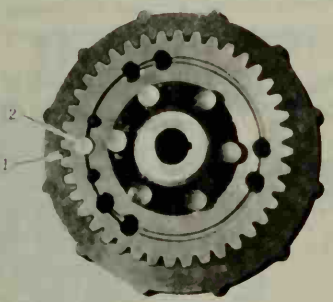
1. Drain the transmission oil. Disconnect the tachometer cable at the engine.
2. Remove the contact breaker cover plate. Marking the position of the stator will speed reassembly. Remove the 3 stator securing screws, and take off the stator.
3. Remove the starter clutch cover. The contact breaker cam shaft assembly will come off with it.
4. Remove the circlip which retains the nylon water pump drive gear, and take off the gear.
5. Remove the electric starter idler gear.
6. Remove the starter clutch assembly bolt, then remove the assembly. Note that two special tools are needed to accomplish this.
7. Loosen the set bolt and take out the tachometer driven gear and sleeve.

Special tools (1, 2) in use removing the starter clutch components

Water pump drive gear (1), electric starter gear (2), tachometer drive gear sleeve (3) and set bolt

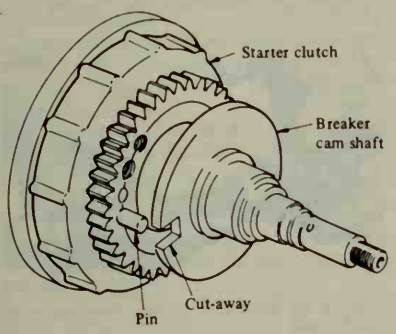
8. Remove the countershaft sprocket cover after removing the left footpeg, and removing the gearshift lever.
9. Bend down the tab on the sprocket lockwasher. Remove the nut. Remove the lockwasher from the shaft, then pull off the sprocket.
10. Remove the oil seal retainer.
11. Remove the gearshift switch.

NOTE: *Steps 10 and 11 are not neces-*



sary unless either of the components are defective, or the crankcases are to be split.

Inspection



1. Check the gear teeth for chipping or wear. Replace any damaged gear.
2. Check the starter clutch rollers and the housing for wear.
3. The contact breaker camshaft rides on two bearings which are mounted in the starter clutch cover. Check the rotation of the shaft. It should be smooth and effortless. Make sure that rotation is not rough or binding. Check the shaft for lateral play.

An oil seal keeps the points compartment free of oil. If seepage is noted, replace the seal. If the seal is taken off the shaft, a new seal should always be fitted.

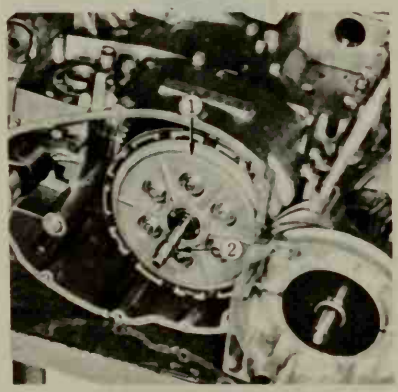
To remove the smaller of the bearings from the starter clutch cover, first remove the snap-ring, then drive out the bearing.

The punch mark and pin must align

Installing the breaker cam

Assembly

1. Reverse the disassembly procedure. Note that the punch mark on the starter clutch housing must align with the pin on the water pump drive gear. Secure the gear-to-housing bolts with thread locking compound.
2. Tighten the starter clutch mounting bolt to 33–40 ft lbs. The starter clutch must be held with the special tool.
3. When refitting the cover, note that the slot cut into the plate of the contact breaker camshaft must engage the pin on the water pump gear.

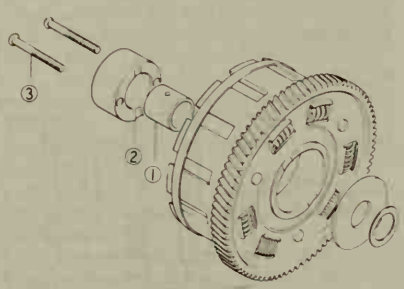


RIGHT CRANKCASE COVER COMPONENTS

The right crankcase covers contain the alternator and clutch assemblies, and the kickstarter return spring assembly.

Removal

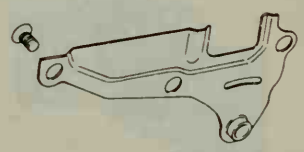
Note that the removal of the alternator rotor requires a special puller.



1. If the clutch is to be removed, drain the transmission oil. Remove the alternator cover.
2. Unscrew the brush holder screws, holding the holder very securely while doing it. A spring bears on the brushes and will attempt to push them out of the holder as the holder is removed. Take the holder off very slowly, so that the brushes do not spring out too quickly.
3. Remove the alternator stator.
4. Remove the alternator rotor bolt. Then use the special puller to remove the rotor.
5. Remove the clutch release mechanism inspection cover. Remove the clutch release shaft nuts, and take off the clutch lever. Detach the clutch cable from the clutch cover.
6. Remove the right footpeg and rear brake lever.
7. Remove the kickstarter pinch-bolt, then carefully pull the kickstarter lever off the splined shaft.
8. Remove all of the securing screws, and pull off the clutch cover.
9. To disassemble the clutch, loosen the six clutch bolts gradually and evenly

Clutch pressure plate (1) and shaft (2)

and when they are all loose, remove them, the springs, and finally the clutch pressure plate and shaft.



10. Take out the clutch plates.
11. Remove the clutch hub nut after bending down the tab on the lockwasher. The clutch housing must be held in place while removing the nut.
12. Remove the hub, then screw two draw bolts into the clutch hub bushing spacer and take it and the bushing off the shaft. Then take off the clutch housing, noting the location of the thrust washers on the assembly.
13. Remove the transmission oil reservoir plate fitted on the crankcase if the cases are going to be split.
14. Remove the kickstarter shaft spring guide, then disengage the spring, and remove it and its holder.

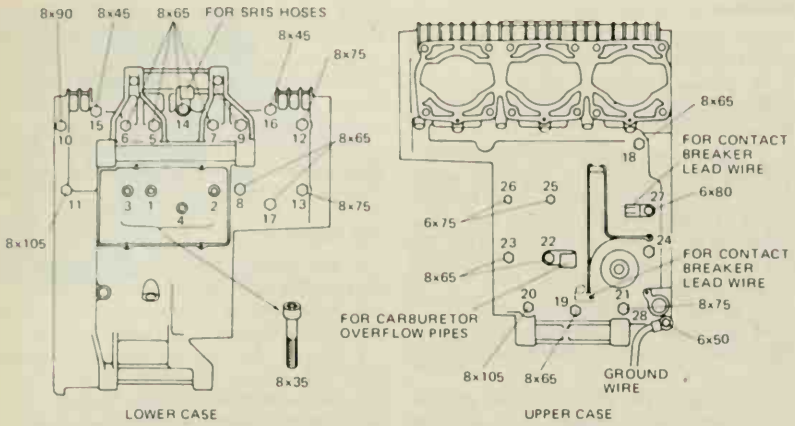
Clutch hub bushing (1), spacer (2), and draw bolts (3)

Inspection

1. For clutch specifications, refer to the chart at the end of this section.
2. Alternator tests are outlined in the "Electrical Systems" section.
3. Check the mating surfaces of the right side-covers for nicks or scratches. Remove with emery cloth. Remove any traces of old gasket or gasket compound from the mating surfaces.
4. Check the kickstarter shaft oil seal. Replace if defective.

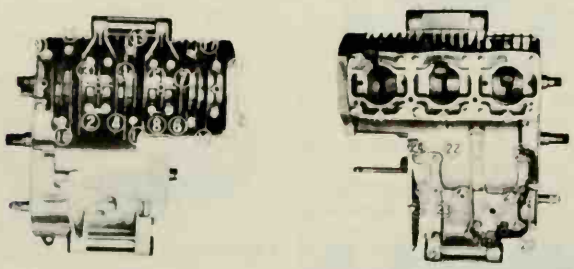
Transmission oil reservoir plate

Assembly



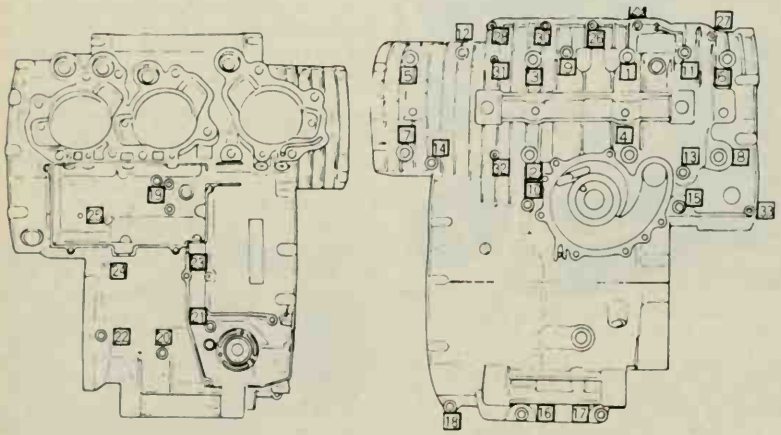
1. Reverse the disassembly procedure Note the following:
2. Use thread locking compound on the transmission oil reservoir plate securing screws and tighten them with an impact driver.
3. Oil the clutch housing bushing and spacer thoroughly with transmission oil. Be sure that the thrust washers are correctly located, and install the assembly.
4. Replace the hub, and tighten the hub nut to 29–40 ft lbs.
5. Squirt some oil into the hole in the clutch sleeve shaft. Install the plates and pressure plate.
6. Adjust the clutch as outlined in the "Maintenance" section.
7. Grease the lips of the kickstarter shaft oil seal before refitting the cover. Be sure to use a new cover gasket.
8. When refitting the kickstarter lever, align the mark on the lever with that on the shaft.

LOWER END AND TRANSMISSION



Splitting the Crankcases

ALL MODELS



1. Remove the engine from the frame. Remove the cylinder head, barrels and pistons.
2. Remove the left and right crankcase covers and the components therein.
3. Remove the oil pump.
4. Remove the electric starter if so equipped.
5. Remove the oil reservoir guide plates where fitted, and the oil seal housing on the transmission shaft if so equipped.

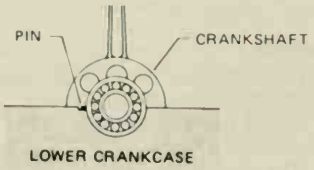
Crankcase bolt loosening and tightening order (GT750)

6. Loosen all of the crankcase bolts on the top and bottom crankcase halves in the reverse of the order shown (the numbers are stamped on the cases).

7. Turn the engine so that the correct side faces up, then tap around the crankcase halves' mating surface with a soft-faced mallet. Lift off the upper crankcase half. The crankshaft and gear clusters will stay in the lower case half.

Assembling the Cases

For crankshaft and transmission inspection procedures, see below.



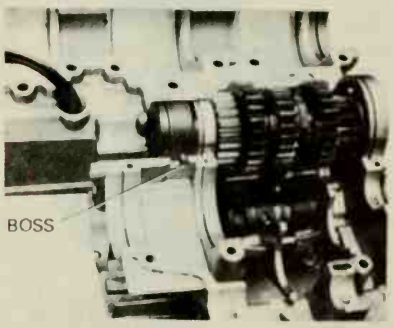
GT380, GT550

1. Generously bathe the crankshaft assembly, especially the bearings, in Suzuki CCI oil.

2. Position each crankshaft oil seal close to the bearing side.

3. Position the pins of each crankshaft bearing so that it sits in its slot in the lower crankcase.

4. When installing the gear clusters, make sure that the bearings are matched with their dowel pins.



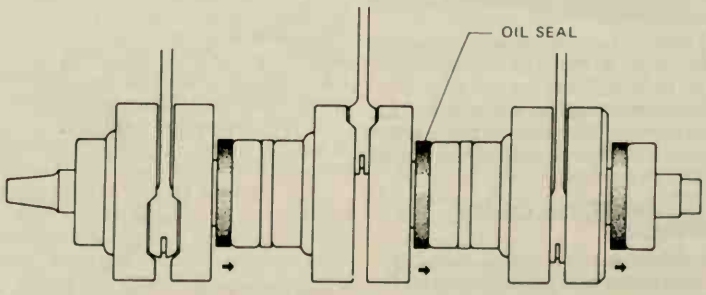
Crank bearing locating pin engaged in lower case

5. Check for smooth operation of all the gears and the shift mechanism.

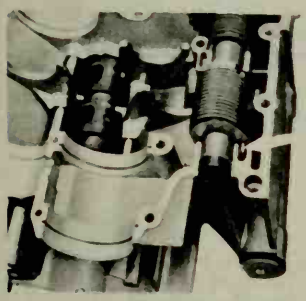
6. GT550: Fit the boss of the countershaft oil reservoir in the groove in the lower crankcase to properly position the oil passage.

7. Make sure that the transmission shafts can be rotated smoothly by hand.

8. Align the kickstarter shaft and ratchet wheel punch marks. Position the starter return spring so that its end is properly seated. Preload the spring by turning the shaft ¾ turn counterclockwise until the boss of the ratchet wheel is resting on the stopper plate.



Fit the countershaft boss into its groove



Aligning the kickstarter ratchet wheel and shaft punch marks

9. Be sure that both crankcase halves have clean mating surfaces. Remove any traces of old gasket compound.

Crankshaft oil seal positions

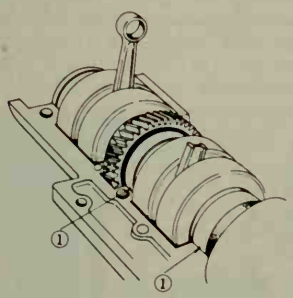
10. Apply a light coat of a liquid gasket material to the upper case half. Let it set for about five minutes, then install the upper case half. Suzuki Bond #4 is recommended.

Kickstarter return spring fitted into the case cutout

11. Install the crankcase bolts and the hose and wiring clamps where applicable. Tighten the bolts in the order indicated by the numbers stamped on the crankcases.

Proper torque settings are:

GT380:
6 mm bolts—9.4 ft lbs.
8 mm bolts—14.5 ft lbs.
GT550:
6 mm—4.4–7.3 ft lbs.
8 mm—9.5–17 ft lbs.



12. Complete the assembly of the right and left crankcase cover components as described in those Sections. Refill the transmission with the correct quantity and grade of oil.

GT750

NOTE: *If the crankcase halves have been replaced, be sure to install the transmission gears supplied with the new parts. Cases and gears are color-coded. Refer to the "Transmission" Section, below.*

1. Lubricate the crankshaft assembly thoroughly with Suzuki CCI before installation.

2. Insert the crankshaft assembly into the lower case, and position the crank bearings so that the punch marks on the bearing races align with the crankcase mating surface.

Aligning the crank bearings with the crankcase marks (GT750)

Note that the end bearing on the right-side of the crankshaft should have its mark aligned with the mating surface at the rear of the crankshaft, while the others should be lined up at the front of the crankshaft.

3. Push all of the crankshaft oil seals (except the one located between the primary gear and the right-side crankthrow) firmly against their bearings.

4. Install the gear clusters, shifter mechanism, and kickstarter assemblies. For detailed installation procedures, see the "Transmission" Section, below.

5. Be sure that both crankcase mating surfaces are clean and free of old gasket material.

6. Apply a light coat of liquid gasket compound to the upper case half, let it set for about 5–10 minutes, then install the upper case half. Suzuki Bond #4 is recommended.

7. Refit the crankcase bolts. Note that wiring clamps are fitted to bolts Nos. 8, 10, and 14. A copper washer goes on bolt No. 13. The engine ground wire is attached to bolt No. 22.

Attach the remaining clamps for the wiring to bolt No. 6.

8. Tighten the bolts in the order indicated by the numbers on the crankcase. Note the following torque specifications:

6 mm bolts—4.3–7.2 ft lbs.
8 mm bolts—9.4–16.7 ft lbs.
10 mm bolts—18.1–28.9 ft lbs.

9. Fill the transmission with the correct amount (2500 cc) of oil.

Crankshaft

ALL MODELS

The crankshafts on all three machines are pressed together. It is impossible to disassemble or assemble the crankshaft without the proper press, and impossible to align the crankthrows and flywheels without the factory jigs.

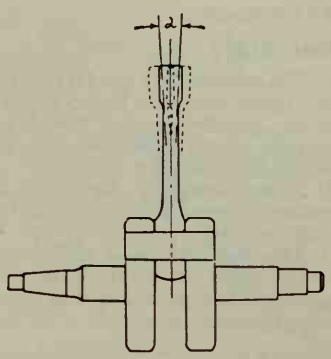
1. Check the connecting rod small end for wear or excessive clearance between the bearing and the piston pin. Clearance should not exceed 0.05 mm (0.002 in.).

2. Check the connecting rods for a bent or twisted condition. There are several ways to do this, but the following is recommended:

Install a piston, without the piston rings, on the connecting rod. Install the crankshaft in the case, if it has been removed.

Refit the cylinder(s).

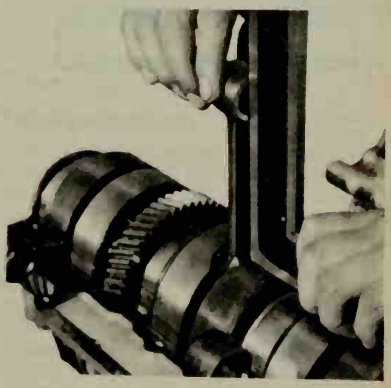
NOTE: *Because of the one-piece cylinder block on the GT750, refit all the pistons and check all of the rods at the same time.*



Push the piston crown left and right with the piston at top dead center. The piston should return to the center of the cylinder bore when released from the right or left. If it does not, and stays off to one side of the cylinder bore, the rod is bent and must be replaced.

3. Check each rod for up-and-down movement. There should be none.

4. Rotate each rod slowly around its crankpin. Note the bearing action. Any roughness, binding, or clicking noise during rotation is indicative of a bad rod bearing.



5. Inspect the big end thrust washers for excessive wear, obvious damage, or discoloration.

6. Check each rod's side-play. This can be done in several ways. A suitable sized right-angle, as illustrated, can be placed on the crankshaft, and used to measure play at the rod small end. Or a dial gauge can be attached to measure small end side-play.

Measuring connecting rod side-play: an indication of big end bearing wear

Standard small end side-play is 0.5–0.8 mm (0.02–0.03 in.). If play equals or exceeds 3.0 mm (0.12 in.), replace the connecting rod bearing.

Checking a connecting rod for straightness

7. Connecting rod thrust clearance (big end side-to-side movement) has a standard value of 0.2–0.6 mm (0.008–0.023 in.). Big end thrust exceeding these values is indicative of worn rod bearings.

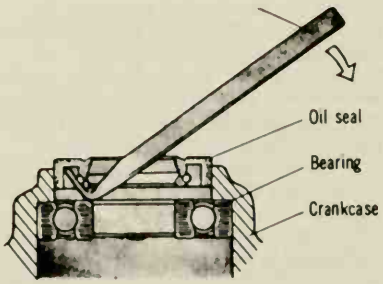
8. If a set of V-blocks is available, or if you can devise some means of turning the crankshaft on a steady plane, check the crankshaft for run-out. If the run-out is measured at a crank flywheel or bearing, divide the result by two, and this will give the amount of bend in the crankshaft.

If more than 0.08 mm (0.003 in.) of bend is indicated, the assembly will have to be straightened.

If the run-out is not excessive, it may be remedied by striking the flywheel with a soft metal mallet where the greatest amount of run-out is measured. Recheck the crank alignment, and repeat as necessary.

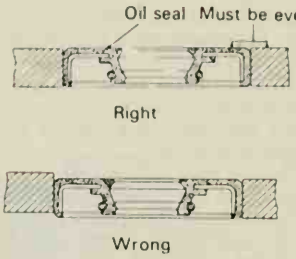
9. Check the rotation of the main bearings, noting any rough movement or noises during rotation. Inspect the oil seals, especially around the lips, for a condition which might cause leakage.

Note that if any bearing is damaged or worn, all of the crank bearings must be replaced. The same is true of the crank oil seals.



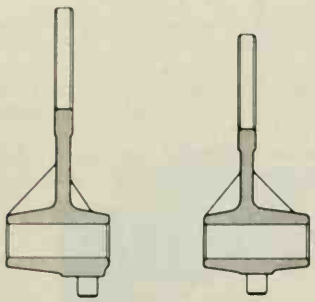
Transmission

GT380, GT550



1. The gear clusters can be lifted out of the lower crankcase. Before doing so, however, note the location of each gear. Note also that the transmission shaft bearings are located by "C" rings.

2. Before removing the shift fork spindles, mark each fork for location to facilitate assembly.

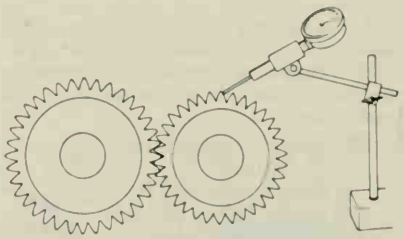


3. After the shift forks are removed, the shift drum can be taken out if the drum stopper, stopper pawls and gear indicator switch are removed.

Removing an oil seal

Correct and incorrect oil seal installation

GT550 shift fork differences



4. Be certain that the transmission and kickstarter shafts are correctly located with the pins in the lower crankcase and that the "C" rings are installed and fitted properly into the bearings.

5. Make sure that the transmission shafts turn smoothly after installation.

6. When assembling the kickstarter shaft, insure that the punch mark on the shaft aligns with that on the ratchet wheel. Be sure that the return spring is correctly fitted with the spring end in place in the case. Make sure that the kickstarter shaft is assembled as shown in the illustration.

GT750

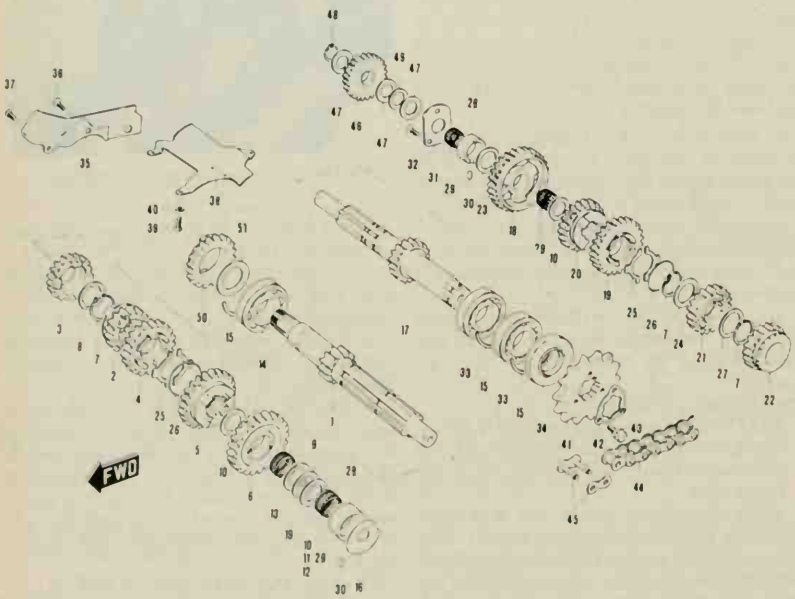
1. The countershaft Second gear must be removed from its shaft with an arbor press if in need of replacement. After this has been done twice, the entire assembly must be replaced.

Measuring gear backlash

2. Gears are color-coded to the crankcases. The color code and chart are shown below.

3. Check all gears for wear by checking the gear backlash. Lock one gear into position and move the other against it while measuring total rotational movement with a dial gauge. The average backlash for the first, second, third, and kickstart gears is 0–0.05 mm (0–0.002 in.), and for all other gears it is 0.05–0.1 mm (0.002–0.004 in.).

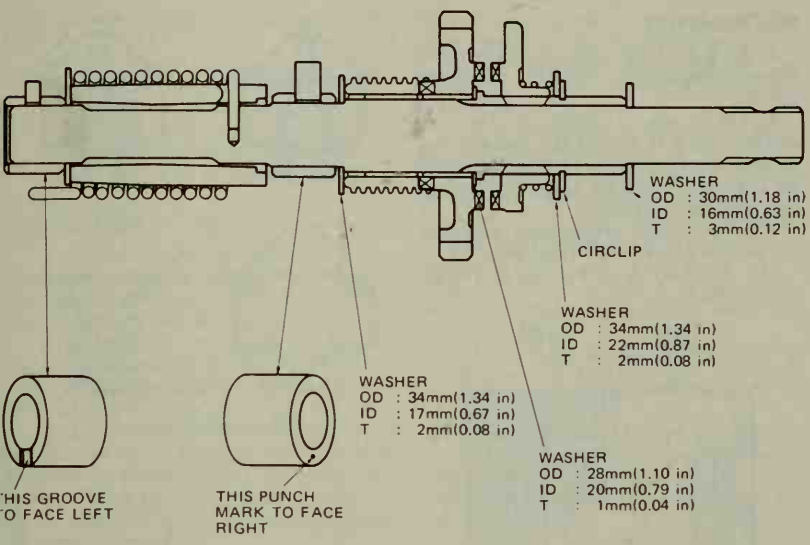
Crankcase Color Code



Crankcase Color	*1st, 2nd Driven Gears*	*Kickstart Drive Gear*
Brown Black Red Yellow	Yellow	Brown
Blue Green White	White	Yellow

4. Average clearance between the shift forks and spindles is 0.05–0.1 mm (0.002–0.004 in.).

5. Thickness of the shift fork fingers is (standard) 4.95–5.05 mm (0.195–0.198 in.). Replace any fork whose fingers measure less than 4.90 mm (0.19 in.).



6. Inspect the shift drum for damage. Note any irregular wear of the grooves. Standard diameter of the shift drum is 44.90–44.98 mm (1.76–1.77 in.).

7. If gears are being replaced, when you purchase gear replacements for the first and/or second gear, you will get two gears in a package. One is marked with a dab of white paint, the other with yellow paint. The crankcase is color-coded, so

check the chart for the appropriate gear to use.

If, for example, the cases are coded brown, the yellow gear will be used. If they are coded green, the white marked gear must be installed.

8. When replacing the kickstarter gear, the same procedure applies, except that the gears are coded yellow and brown.

9. Oil all components thoroughly before assembly. Insert the kickstarter ratchet wheel onto the shaft so that the punch marks on the wheel and shaft align.

10. Note that the oil hole in the shaft should face upward when the kickstarter contacts the kickstarter guide.

11. Install the kickstarter assembly into the lower case, then secure the starter guide with the two screws. The screws should be secured with thread locking compound.

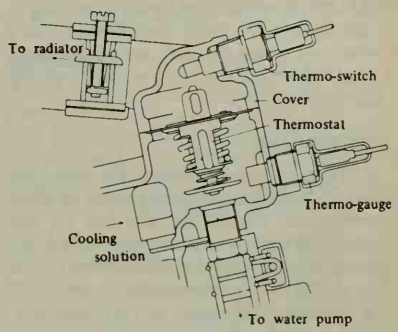
GT750 COOLING SYSTEM



The GT750 water cooling system is much like that used in standard automobile practice. The system consists of a radiator, thermostat, reservoir tank, cylinder block and head water jacket, fan, and water pump.

The water pump is located in the lower crankcase. A centrifugal-type unit, it is driven off the crankshaft through the starter clutch gear.

The pump takes water from the radiator and circulates it through the cylinder block and head water jacket, the thermostat, the radiator, and then back to the pump.

When the engine is cold, the thermostat routes the water directly back to the pump via the by-pass hose, rather than having it pass through the radiator.

A thermostat-activated switch controls the electric fan.

Thermostat and temperature control components

Maintenance

The cooling system should be drained and refilled with the proper amount of water/coolant solution every two years. Refer to "Maintenance", for procedures and the correct percentages of water and coolant to use to suit various climatic conditions.

CAUTION: *Use only distilled water in the cooling system.*

Troubleshooting

1. In case of engine overheating, first check the coolant level, and top up as necessary. Check the system for leaks as well.

2. If the overheating persists, check the thermostat operation; replace it if defective. See procedures below for thermostat checks.

3. Then check the water pump. See below. If this unit is okay, it may be that the system is blocked somewhere. Flush out the radiator. Check for rust or scales in the water.

4. Overheating may also be caused by incorrect ignition timing, dragging (drum) brakes, or a mechanical malfunction.

Since the water cooling system on the GT750 has a reputation for reliability, it is worthwhile checking these points before disassembling any cooling system components.

5. Failure of the engine to warm up properly can be caused by a defective thermostat which remains open all the time. Replace the thermostat if need be. Extremely cold weather may also cause this, in which case covering the radiator with a small piece of cardboard until the engine reaches operating temperature is recommended.

6. Excessive noise in the engine not caused by the crankshaft, clutch or gears may be due to either a defective water pump bearing or a loose or bent impeller. Replace the pump or impeller as needed.

Radiator

REMOVAL

1. Drain out the coolant solution.

2. Remove the gas tank, the radiator inlet and outlet hoses, the coolant inlet line, the reservoir tank and its hose, and the cooling fan and shroud.

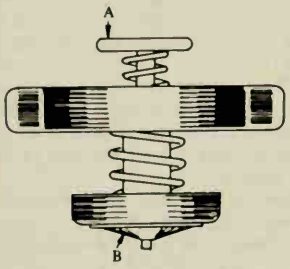
3. Remove the radiator crash bars and the radiator assembly.

NOTE: *When the radiator assembly is removed, keep each set of shims and washers separate and mark their locations. The radiator must be correctly installed.*

INSPECTION

1. Inspect the radiator for damage, signs of leakage, mud-encrusted or dirty cooling fins. Check that the fins are not bent or otherwise damaged. Slight leakage can be remedied with a radiator additive designed for that purpose.

2. Internal damage to the radiator, such as that which might have been caused by the freezing of the coolant solution, cannot be repaired, and the unit must be replaced.

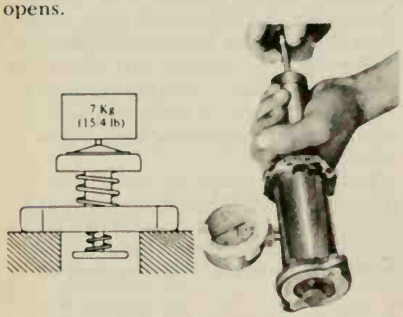


3. If more than 20% of the total radiator cooling surface area is incapacitated by fin damage or irremovable deposits, replace the radiator.

4. Inspect the radiator cap for condition. The cap is designed to maintain a system pressure of about 27 psi (1.9 kg/cm²).

The radiator cap is fitted with a safety valve, "A" (see the accompanying illustration).

It is installed for releasing steam from the system.



It is pressed down prior to removing the radiator cap on a hot engine and will open "B" allowing any builtup steam to

Radiator cap with safety valve ("A" and "B")

escape safely so that the cap can be removed.

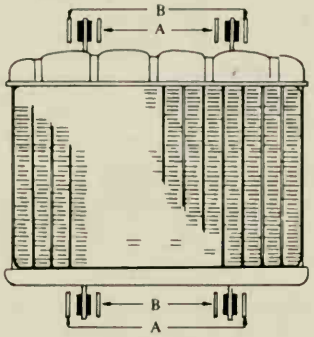
5. The radiator cap may be checked by placing a weight of 15.4 lbs (7 kg) on it as shown to observe whether or not the cap opens.

Two radiator cap tests

6. If a pressure gauge is available, the cap should begin to open at about 27 psi (1.9 kg/cm²).

Replace the cap if it fails the pressure test.

7. Check the condition of all hoses and replace any which show even minor cracking or rotting.



INSTALLATION

1. To install the radiator, reverse the removal procedure. Note the following points.

2. There are 3 different sizes of washers used to mount the radiator and these are color-coded. The radiator must be mounted correctly to prevent vibration and stress damage.

The following information concerns the proper placement of washers:

a. Washer "A" is 2.0 mm (0.079 in.) thick.

Radiator mounting shims (refer to the text procedures)

Washer "B" is 1.6 mm (0.063 in.) thick.

Washer "C" is 0.8 mm (0.031 in.) thick.

b. When the radiator is marked with white circles on the mounting plates, install the washers as illustrated.

c. When the radiator is not marked, mount it only with "B" washers.

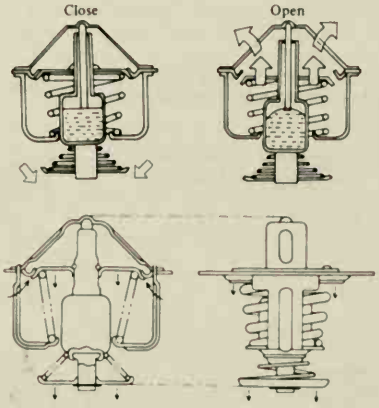
d. In instances where there is a white circle at the top only, fit "A" and "B" washers to the top mount as illustrated, and fit only "B" washers to the bottom.

e. In instances where only the bottom mount is marked, fit "B" washers only to the top mount, and "A" and "B" washers, as illustrated, to the bottom.

f. If, after installing the washers in their prescribed positions, there is still a gap, use "C" washers as shims until a flush mounting is obtained.

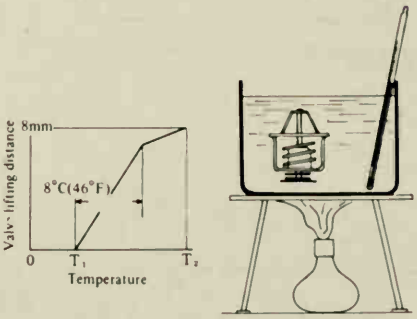
Thermostat

The thermostat is used to direct the flow of the coolant solution. When the coolant reaches 180°F, the thermostat opens and circulates the water through the radiator.



The thermostat is the wax-pellet type and the valve is designed to open and close with the expansion and contraction of the pellet.

1. Make sure that the pellet is not cracked or damaged in any way.



2. To check operation, immerse the thermostat in water and heat the water noting the operation of the thermostat as the temperature climbs.

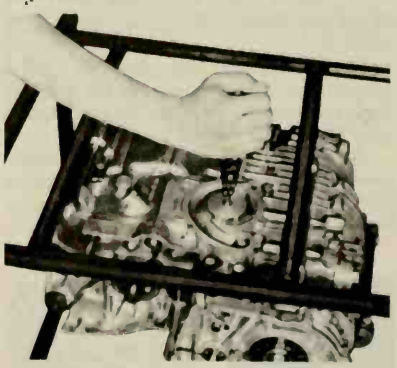
3. At 180°F, the valve should begin to open; at 203°F, it should be completely open. The operating stroke of the thermostat in this position should be 8.0 mm (0.3 in.).

If the thermostat operation does not coincide with this standard operation, replace the thermostat.

Thermostat operation

Thermostat operation as a function of water temperature

Water Pump



REMOVAL

1. Drain the coolant.

2. Remove the center muffler.

3. Carefully remove the water pump cover, taking care not to damage the mating surface.

4. Remove the impeller circlip with a pair of snap-ring pliers, then remove the impeller.

Removing the impeller circlip

5. Remove the water pump holder circlip with the snap-ring pliers.

6. Then pull out the pump holder with a pair of pliers.

CAUTION: *Protect the mechanism by covering the pump driven shaft with a rag or piece of rubber while withdrawing the holder. Do not allow the pliers to contact the driven shaft directly.*

DISASSEMBLY

The water pump driven shaft and bearing can be removed from the holder by

heating the holder assembly to 165–185° F.

The driven shaft and bearing can then be taken out of the top of the holder.

NOTE: *The water pump and oil seals in the holder should not be removed. The holder and seals are replaced as an assembly if any component is damaged.*

INSPECTION

1. Clean all parts thoroughly.
2. Inspect the bearing for wear or damage. If bearing action is rough or noisy, replace the bearing.
3. Inspect the pump driven shaft for wear or damage. If the shaft is rusted or has corrosion built up on it, remove such deposits with emery cloth.
4. Inspect the impeller blades for deflection or other damage. The impeller cannot be repaired, and should be replaced if any type of damage is noted.
5. Check that the impeller does not contact the crankcase or pump case. If it does, check the shaft and bearing.
6. Nominal clearance between the impeller and the crankcase is 0.5–1.5 mm (0.02–0.59 in.).
7. Check the water pump drive gears and bearings for any wear or damage.
8. Inspect the pump sealing seat and corresponding area of the pump holder for wear or scoring. Replace both the sealing seat and the holder if any unusual marks are noted.
9. Check the condition of the pump holder O-ring, and replace it as necessary.
10. Check the condition of all other O-rings and seals. Replace any part which is even suspected of damage.

NOTE: *The coolant is sealed with a pump seal, the sealing seat, and an O-ring inside the sealing seat.*

The transmission oil is held by an oil seal.

There are, in addition, two more O-rings outside of the pump holder.

ASSEMBLY

1. Assembly is the reverse of the disassembly and removal procedure.
2. Lubricate the holder with fresh oil during installation. Align the holder port with the crankcase port. The notch on the holder top will align with the crankcase bolt.
3. Insert the impeller onto the pump driven shaft and secure it with the circlip. Check the gap between the impeller and crankcase with a feeler gauge. It should be 1.5 mm (0.59 in.). If the gap is not correct, remove the pump driven shaft from the holder, and realign it in the holder.
4. Apply a liquid gasket material to both sides of the water pump case gasket before mounting the pump case.
5. Refill the system with the correct amount and mixture of water/coolant solution.

LUBRICATION SYSTEM

GT750 CCI system

OIL PUMP

NOTE: *Due to the exacting tolerance to which it is made, the oil pump should never be disassembled. If trouble is traced to the pump, the unit must be replaced rather than repaired.*

Troubleshooting

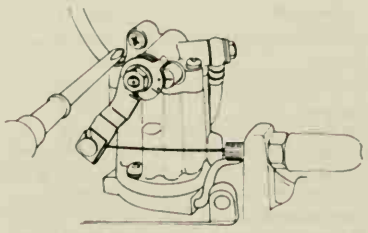
Before beginning any repair of the lubrication system, refer to the following, as it may help.

In the event of piston seizure not caused by any engine component failure, check the oil pump cable adjustment; then check for air in the oil lines (see "Bleeding," below), clogged lines, defective SRIS check valves (see "SRIS", below), low quality oil, or a blocked oil tank filler cap breather hole.

In case of excessive smoking at the exhaust pipe, check the oil pump cable adjustment; check for clogged or pinched SRIS lines, faulty SRIS check valves, or low quality oil (see "SRIS", below).

In case of excessive oil consumption, check the oil pump cable adjustment, and then check for oil leakage at the pump or lines.

If abnormal oil consumption is noted, and assuming that the cable is properly adjusted, the oil pump should be replaced, and a known workable oil pump substituted. If this does not cure the problem, the check valves may be defective.



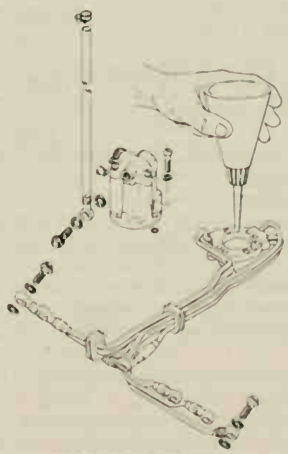
Adjustment

This procedure is covered in "Maintenance".

Bleeding

The oil pump is fitted with a bleed screw. Refer to the illustration.

1. In the event of air bubbles in the line from the oil tank to the pump loosen the bleed screw, and observe the oil flow. When the oil seems to be free of air bubbles, retighten the screw.



Oil pump air bleed screw

2. Check the lines from the oil pump to the engine for air bubbles. If present, they may be removed in either of the following ways, depending on the amount of air present in the lines:

a. If only a small amount of air bubbles are present, start the engine, and, with your hand, hold the oil pump lever full on until you feel all of the air is expelled from the lines.

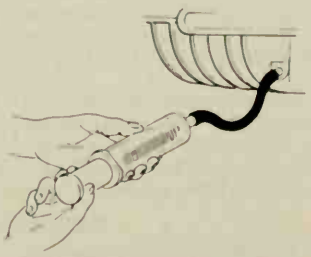
b. If a larger quantity is present, remove the oil pump (see "Removal", below), and force clean CCI oil into each of the oil feed lines as shown. After this is done, refit the pump, and carry out procedure "a" above.

Priming the CCI lines

Pump Removal and Installation

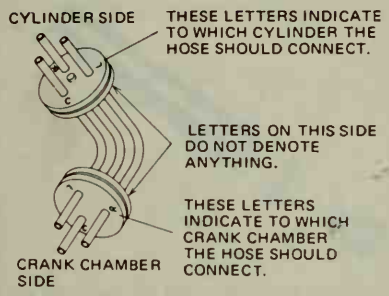
1. Remove the oil pump cover.
2. Disconnect the pump cable from the pump lever. Disconnect and plug the feed line from the oil tank.
3. Remove the securing screws, and remove the oil pump.
4. If the pump-to-engine feed lines are removed, blow them clear; check the external condition of the lines and gaskets. Replace any worn components.
5. Before installing the lines, force Suzuki CCI oil into the crankcase oil passages.
6. Be sure that the lines are properly connected. Tighten the banjo bolts to 1.8 ft lbs.
7. After the lines are installed, fill them with CCI oil. Then install the pump, and connect the oil tank feed line. Bleeding the system, as described above, is recommended.

SRIS



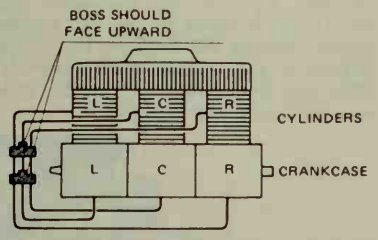
NOTE: *The arrangement of the SRIS pipes is important, so note their location before removing them.*

REMOVAL



1. Remove the oil line guide plate from the lower crankcase, where fitted.
2. Disconnect the SRIS lines at the crankcase lower side by removing the securing clips with a screwdriver.
3. The SRIS check valves will be either press-fit into position (as on early models), or threaded in.

INSPECTION



1. Check the lines for cracks, leaks, or other damage.
2. Check the operation of the check valves with a syringe as shown. The valves should be able to form an effective seal against oil traveling in this direction.
3. The newer type valves are fitted with a nylon mesh filter, and this should be cleaned if the lines are disconnected.

FUEL SYSTEMS

NOTE: *For carburetor theory, component inspection, and troubleshooting, refer to "Carburetors" in the General Information section.*

CARBURETORS

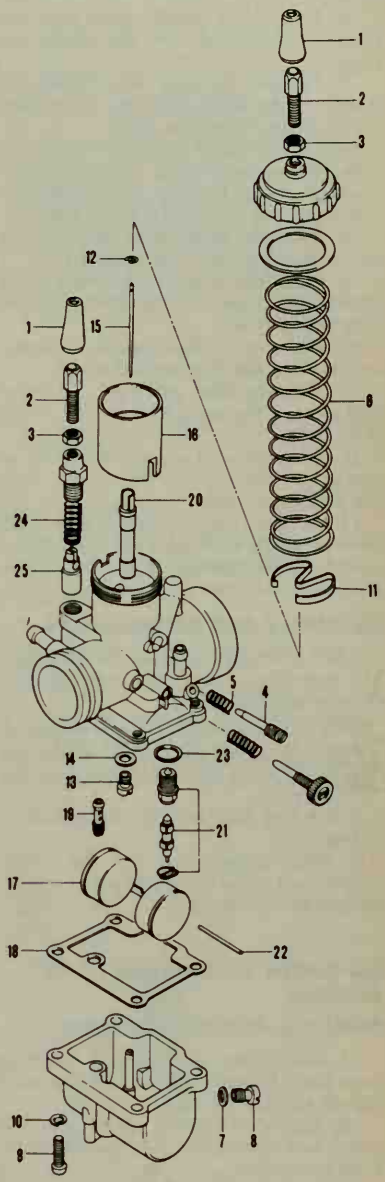
The GT380, GT550, and GT750 all use different types of Mikuni carburetors.

All "J" and "K" models (1972–73) use cable-operated "SC" series carbs. The GT380 and GT550 "L-A" (1974–76) also use these carburetors, but throttle slide movement is controlled by a pulley and linkage.

The GT750 "L-A" use BS40 constant vacuum (CV) carburetors.

Note that the removal procedure will vary according to the type of carburetor and throttle control arrangment.

SC-Series Carburetors ("J" and "K" Models)



REMOVAL AND DISASSEMBLY

1. To remove the carburetors on all "J" and "K" models, disconnect the fuel lines, loosen the air cleaner and manifold clamps on either of the outside carbs, pull the carburetor toward the air cleaner and detach it from the rubber hoses.

2. Unscrew the carburetor cap and pull out the throttle slide assembly. Unscrew the starter plunger.

3. Repeat this procedure for the other two carburetors.

CAUTION: *The carburetors are aligned on the manifold hoses by a slot and rib arrangement; therefore, never attempt to twist the carburetor while it is still attached to the manifold hose.*

4. Detach the throttle cable from the throttle slide, and free the slide and needle.

5. Remove the clip which holds the needle in the slide, and remove the needle from the top of the slide.

NOTE: *The small circlip on the needle determines midrange mixture; note which groove the clip is positioned in if it is to be removed for any reason.*

6. Turn the carburetor body upside down. Remove the float bowl screws.

7. Carefully remove the float bowl and gasket. Push out the float pin, and remove the float.

8. Remove the float needle; unscrew and remove the float needle seat.

9. Unscrew the pilot jet. Unscrew and remove the main jet from the carburetor body.

10. Unscrew and remove the pilot air screw and the throttle stop screw from the carburetor body.

11. Remove the needle jet, if desired, by very gently drifting it out through the throttle slide passage in the body, tapping from the main jet side.

ASSEMBLY AND INSTALLATION

1. To assemble, reverse the disassembly procedure. Use all new gaskets, O-rings and washers.

NOTE: *If the needle jet was removed, install it so that the cut-out at the top of the jet faces the ENGINE side of the carburetor.*

2. Set the float level as described in "Tune-Up".

3. After installation, set the cable slides, and tune the carburetors as described in "Tune-Up".

SC-Series Carburetors ("L-A" Models)

REMOVAL AND DISASSEMBLY

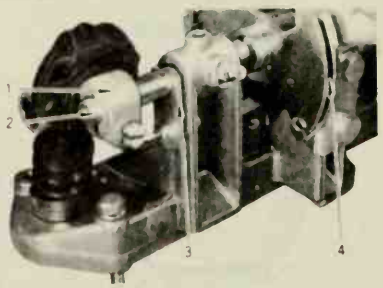
1. Disconnect the fuel line and vacuum hose. Remove the gas tank. Remove the air cleaner assembly.

2. Run the throttle cable adjusters down and disconnect the throttle cables from the pulley.

3. Loosen the carburetor manifold clamp screws and take out the carburetors.

4. Remove the choke lever screw. Exercise caution when removing the screw as the lever is spring-loaded.

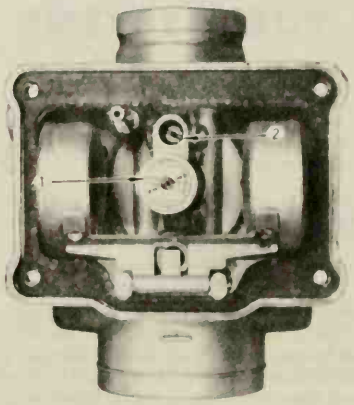
5. Loosen the starter rod screws and pull out the starter rod.



6. Remove the two carburetor cap screws from each carburetor, and pull out the throttle slide assemblies.

7. Disassembly of the throttle slide assemblies is neither necessary nor recommended for routine cleaning, since the slides must be synchronized during assembly. If replacement of any parts is necessary, the slide components must of course be disassembled. This is done by lifting up the rubber boot on one of the slide assemblies. Remove the upper and lower throttle slide adjustment nuts, disengaging the throttle rod from the throttle slide arm. Separate the components.

8. If the removal of the needle is required, remove the needle set plate screws and take out the needle.



9. Repeat the procedure with the remaining throttle slides, if necessary. Do not mix slides and needles. Keep them separate for installation in their own carburetors.

10. To disassemble the linkage, remove the throttle slide arm pinch screws and pull off the arms, removing their woodruff keys from the shaft. Remove the shaft stopper screw and separate the components.

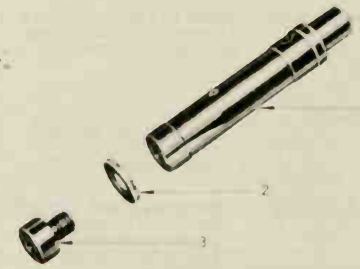
11. To disassemble the carburetors themselves, remove the float bowl screws, and take off the float bowl and gasket.

Main jet (1) and pilot jet (2)

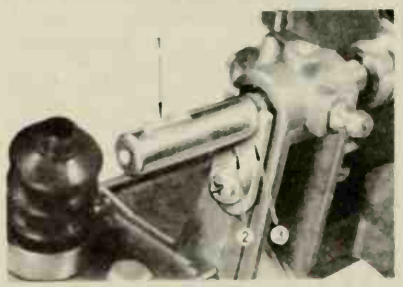
12. Push out the float pin and remove the float assembly and float needle.



13. Unscrew and remove the main jet, pilot jet, and float needle seat and their washers, if fitted.

14. The needle jet may be removed after the washer is removed with a wooden drift by tapping it gently out of the carburetor from the main jet side (driving it into the bore).

15. Unscrew and remove the starter plunger assembly, and pilot air and throttle stop screws.



ASSEMBLY AND INSTALLATION

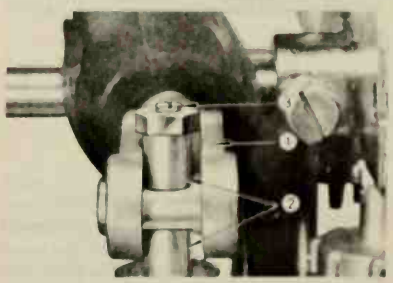
1. Use new o-rings, gaskets, and washers. Assembly of the carburetor body is the reverse of disassembly. Note that the needle jet is positioned by means of a pin at the lower portion of the needle jet holder. Carefully insert the needle jet so that the slot in the jet aligns with this pin, and press home. Do not force the jet until alignment is ensured.

Needle jet with locating slot (1), washer (2) and main jet (3)

2. If the pulley and linkage was disassembled, be sure the carburetor cap screws are in place in the cap casting before refitting the linkage. Install the linkage in the reverse of disassembly. Note that the pulley and throttle slide arms are located by keys.

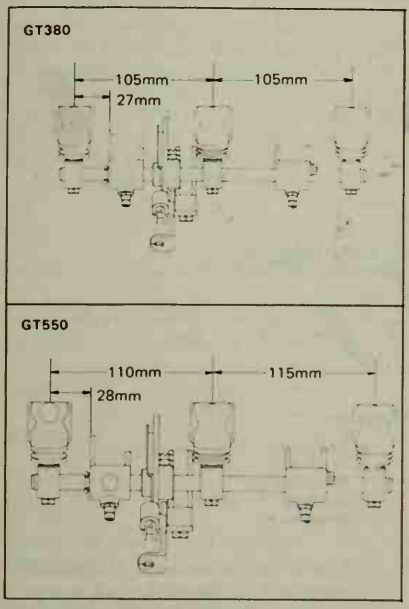
Throttle slide shaft installation: woodruff key (1) to locate arms. Install the stopper (3) so the lug (2) enters its hole in the holder column

When installing the slide shaft stopper, align the lug of the stopper with the hole in the shaft holder column.



3. Lubricate the shaft grease fitting with chassis grease until some shows at the shaft.

4. Position the pulley so that the thick side bears against the throttle slide stop screw, and secure the pulley pinch screw.



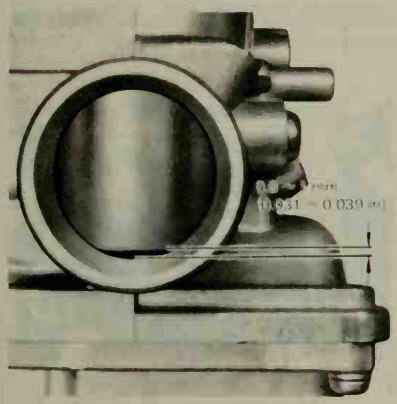
5. Lubricate the bearing surfaces of the throttle slide arms and insert the arm shafts.

6. When installing the slides, be sure the cut-away faces the front of the carburetor. If the slide has a punch mark, it must be installed on the side of the carburetor with an inspection plug.

7. Thread the upper throttle slide adjustment nut on so that a few threads from the throttle rod protrudes.

Throttle slide arm (1), adjusting nut (2), and throttle rod (3)

Throttle slide arm installation positions

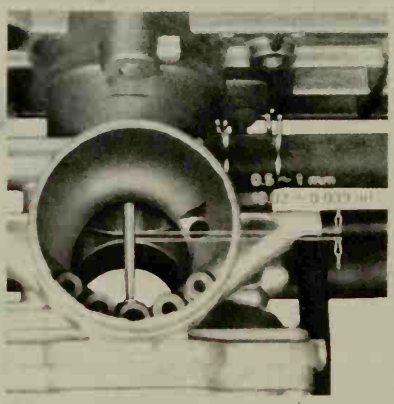


8. Secure the throttle slide arms at the proper distances apart. Refer to the illustrations.

9. Synchronize the slides after completing assembly.

THROTTLE SLIDE SYNCHRONIZATION

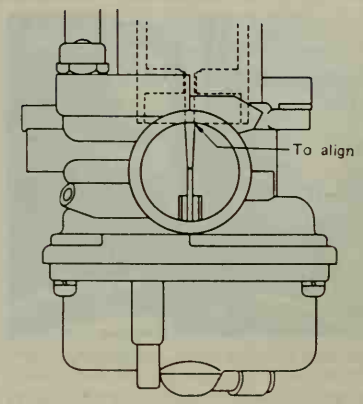
1. Turn the throttle slide stop screw in as far as possible, then back it out 1½ turns.



2. Use the throttle slide adjustment nut atop each carburetor so that there is a gap of 0.8–1.0 mm (0.031–0.039 in.) between the bottom edge of the slide and the carburetor bore. The measurement is made on the engine side of the carburetors.

Slide synchronization, initial step using the slide adjustment nut

3. Turn the pulley to the full-open position and check that the distance between the top of the carburetor bore and the bottom edge of the throttle slide is 0.5–1.0 mm (0.02–0.039 in.). If it is not, adjust the full-open stop screw until the proper clearance is obtained.



4. Hold the pulley so that any of the throttle slides is perfectly aligned with the top of the carburetor bore. As in the above instances, check at the engine side of the carburetor, aligning the bottom edge of the slide with the top of the bore.

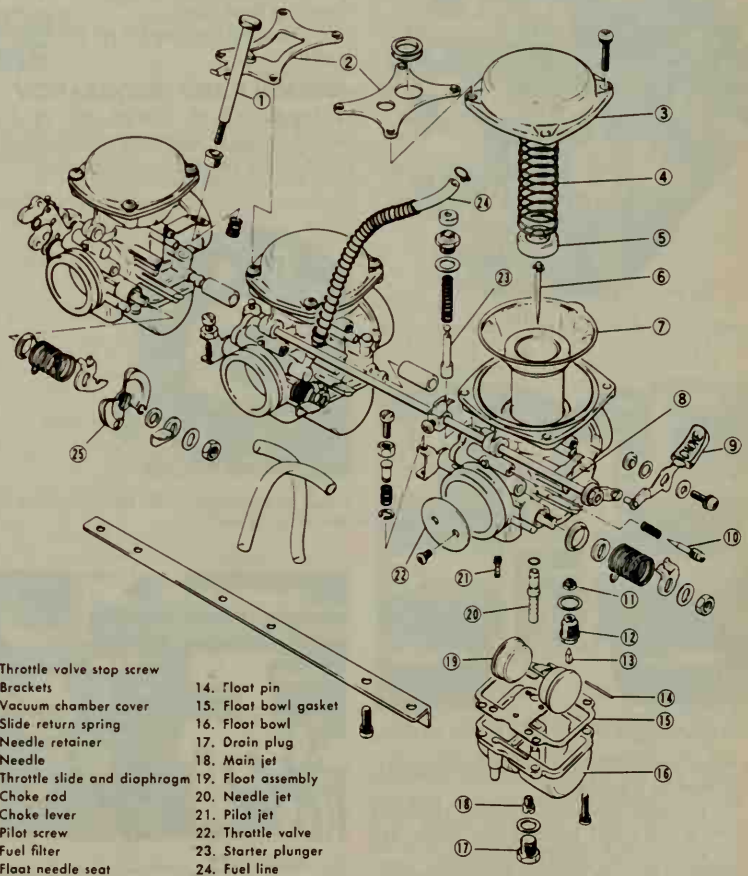
Slide synchronization, second step using the full-open stop screw

5. All three slides must be in the same position for synchronization. After aligning the one slide as in Step 4, hold the pulley in place, and use the throttle slide adjustment nut to bring the other two slides into alignment. Tighten the nuts securely.

6. Adjust the pilot air screws, cables, and make final adjustments as outlined in "Tune-Up."

Slide synchronization, final step: all three slides must align as shown

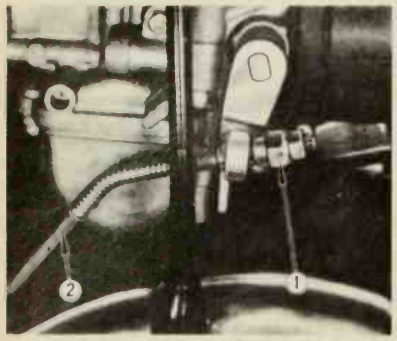
CV-Carburetor



The GT750L-A models use three BS40 constant velocity carburetors.

REMOVAL

1. Disconnect the fuel and vacuum lines. Remove the gas tank and air cleaner.



2. Run the throttle cable adjusters down all the way and disengage the cables from the pulley.

3. Loosen the oil pump control rod adjusting nut and disconnect the rod from the lever.

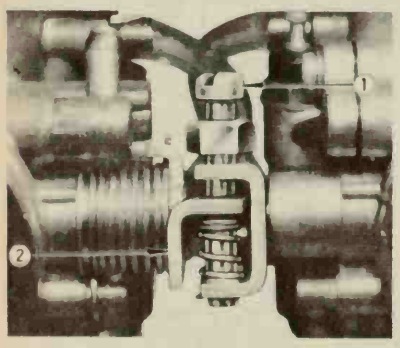
4. Loosen the carburetor manifold clamp screws. Remove the carburetors as a unit.



DISASSEMBLY

All major carburetor components are accessible for cleaning or service without separating the three units. Disassembly of the linkage is not recommended unless absolutely necessary (see Step 1).

1. Loosen the three choke rod screws and pull out the rod after disengaging it from the choke lever and turning it to clear the lever. Turn the throttle adjusting screws out so that there is clearance between the end of the screw and the throttle lever.

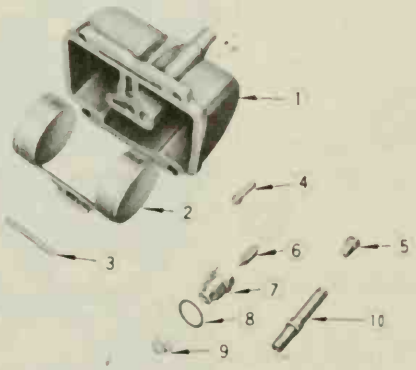
2. Remove the four vacuum chamber cover screws and remove the cover, return spring, and throttle slide.

NOTE: *Do not mix the throttle slides. Each must be reinstalled in its own carburetor.*

3. Remove the drain plug from the float bowl.

4. Unscrew and remove the main jet.



5. Remove the float bowl screws and take off the bowl and gasket.

6. Push out the float pin and remove the float assembly.

7. Remove the float needle. Unscrew and remove the float needle seat. Remove the fuel filter.

8. Unscrew and remove the pilot jet from the float bowl.

9. Remove the needle jet from the carburetor.

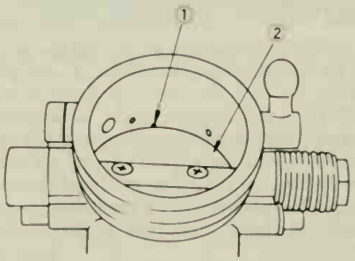
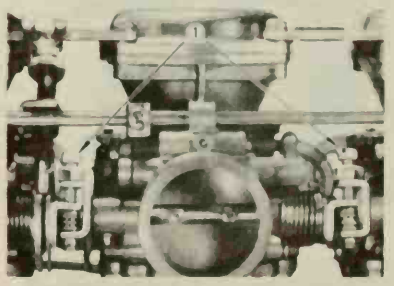
ASSEMBLY AND INSTALLATION

1. Assembly is the reverse of disassembly. Note that the diaphragm is notched for proper installation.

Install the diaphragm so the tab engages the carburetor notch (1 and 2)



Use a thread-locking agent on the choke rod screws (1)



2. Use a non-permanent thread-locking compound on the choke rod screws.

3. Synchronize the throttle valves by aligning the edge of the valves with the edge of the No. 1 by-pass outlet. Use the throttle adjusting screws to make this adjustment.

4. Adjust the pilot screws, the cables (after installation) and make final adjustments as outlined in "Tune-Up."

Synchronize the throttle valves by aligning each with the edge of the by-pass outlet (1) with the throttle adjusting screws

Fuel Petcock

Occasionally check the fuel petcock. The sediment bowl should be removed and cleaned. The filter should be washed in gasoline and blown dry.

Before refitting the sediment bowl, check the condition of the gasket. Replace it if it is damaged or worn looking.

The petcock can be removed from the gas tank by removing the two securing

nuts. In this event, closely check the condition of the O-ring which seals the gas tank at that joint and replace it if need be.

Note that the fuel petcock is of the diaphragm type. The lever should remain in the "ON" position at all times unless you are switching to reserve. ("RES").

Use the prime ("PRI") position ONLY if the carburetor float bowls have been drained for some reason. When the engine is started, turn back to "ON" immediately.

After removing the plate at the back of the fuel petcock, check the condition of the diaphragm and replace it as necessary.

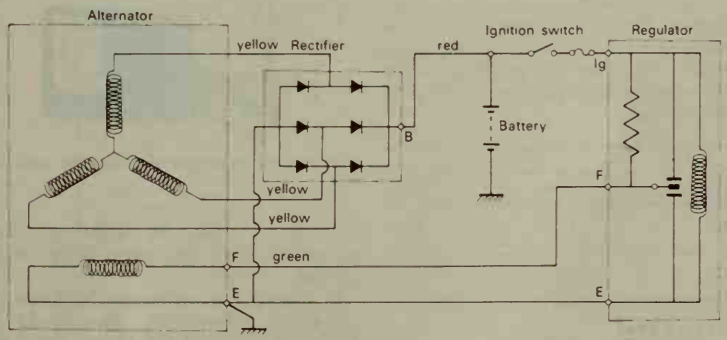
ELECTRICAL SYSTEMS

The electrical systems for all of the Suzuki Triples are basically similar. In each case a 12-volt battery in conjunction with three ignition coils and three contact breaker points is used to provide spark.



The GT550 and GT750 are fitted with electric starters. The GT550 starter drives the engine through the clutch; while the GT750 starter drives the crankshaft through an intermediate gear.

CHARGING CIRCUIT

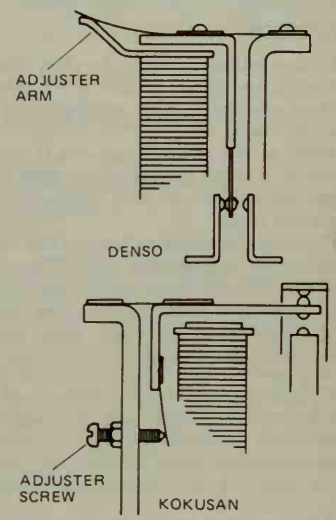
In the event of electrical troubles such as the battery overcharging, or failing to hold a charge, perform the following tests:

a. If the battery is overcharging, the problem is probably the voltage regulator.

b. If the battery is going dead, the problem may be the regulator, rectifier, or alternator.

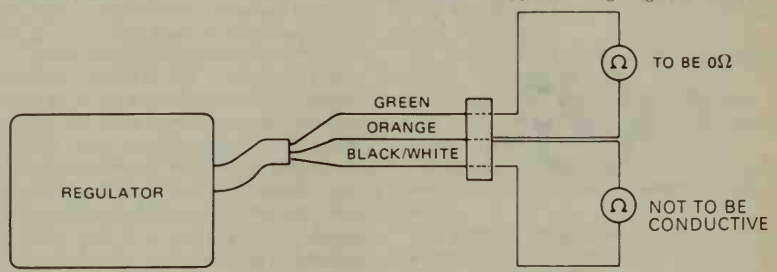
Charging circuit

Perform the tests outlined below.



Component Tests (GT380, GT550)

CAUTION: *For all of the following "in circuit" tests, the battery must be fully charged, or erroneous results will be obtained.*

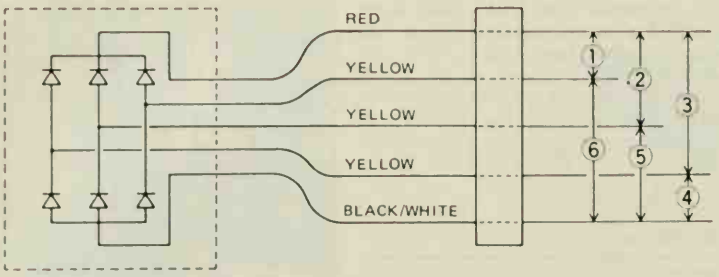


VOLTAGE REGULATOR

1. Start the engine and run it at 2500 rpm. Measure the voltage across the positive battery terminal and ground. A reading of 13.5–14.5 volts should be obtained. If the reading is too high, replace the regulator, or carry out further tests on it as described below. If the voltage reading is lower than the amount specified, test the regulator and then the other components.

2. With the engine OFF, disconnect the voltage regulator. With the ohmmeter, measure the resistance between the green and the orange leads. Resistance should be zero. If the meter reads resistance, replace the voltage regulator.

Two types of voltage regulator



Voltage regulator resistance tests

3. Measure the resistance between the orange and the black/white leads. Resistance should be infinite. If resistance is less than this value, replace the alternator.

4. Remove the regulator cover. Press down on the regulator arm, so that the moving contact point is not in contact with either of the stationary points. Measure the resistance between the green and the orange leads. Resistance should read about 10 ohms. If the resistance is not near this value, adjustment is not possible, and the regulator must be replaced.

5. Refer to the accompanying illustra-

Rectifier test points

2. Check the resistance between each of the yellow leads and the stator body. This is a test for a grounded coil. In each case, the resistance should be infinite. If, in any case, it is not, the stator assembly must be replaced.

3. Check the continuity between each of the 3 yellow leads. If the 3 leads were assigned the letters "A," "B," and C," you would check the continuity between A–B, A–C, and B–C.

In each case, the ohmmeter should read less than 1 ohm resistance. The exact specifications are 0.26–0.1 ohms for the Denso alternator, and 0.43–0.1 ohms for the Kokusan coil.

If the resistance in any of the 3 tests is higher than this value, an open circuit exists, and the stator assembly must be replaced.

tions. Note that two types of regulators are used.

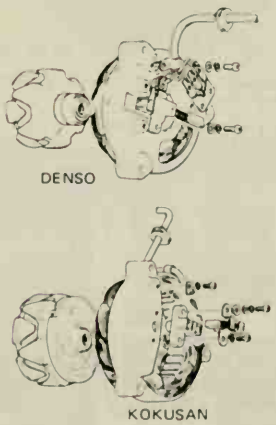
On the "Denso" regulator, bend the adjusting arm to attain the proper voltage. Bend the adjuster arm *up* to raise voltage output, and *down* to decrease output.

On the "Kokusan" regulator, turn the adjusting screw *in* to increase the voltage output, and *out* to decrease output.

RECTIFIER

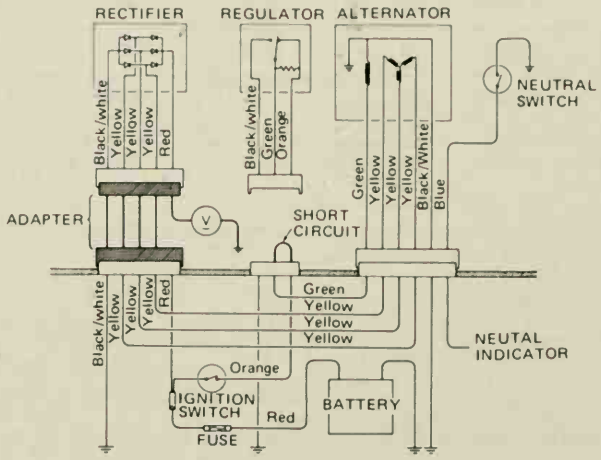
If the regulator seems to be okay, check the operation of the rectifier. This is done with an ohmmeter. The rectifier must be disconnected.

Refer to the illustration which shows the wiring of the rectifier. Note that each of the six diodes will pass current in one direction only.



Connect the negative lead of the ohmmeter to the red rectifier wire. Then connect the positive meter lead to each of the yellow rectifier leads in turn. The meter must show less than a few ohms resistance in all three cases.

Now reverse the connections so that the positive meter lead is connected to the red rectifier lead, and the negative meter lead is connected to each of the yellow rectifier wires in turn. The meter must read a higher resistance in each case.



If the rectifier has been satisfactory to this point, connect the positive meter lead to the black/white rectifier lead and the negative meter lead to each of the yellow rectifier wires in turn. Resistance in each case must be close to zero.

Now reverse the meter leads and perform the tests again between the black/white lead and each of the yellow leads. Resistance should be much higher.

If the resistance in any of the above cases differs from the normal reading, the rectifier *must* be replaced.

The two types of alternator in use

Alternator no-load test (GT380, GT550)

ALTERNATOR

No-Load Test

CAUTION: *The alternator no-load test must be performed quickly to avoid burning out the alternator coils.*

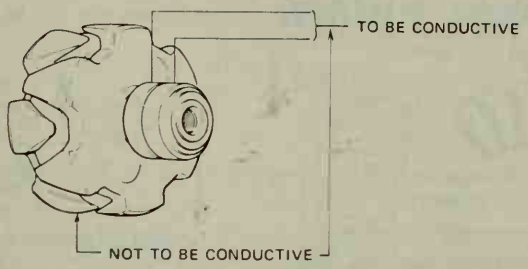
1. The battery must be fully charged.
2. The alternator should be cold.
3. Disconnect the voltage regulator coupler. Then use a small piece of wire to connect the green wire from the alternator to the orange battery wire. Refer to the "short circuit" in the illustration.
4. Disconnect the red lead coming from the rectifier at the rectifier wiring coupler, and connect it to one side of a voltmeter; connect the other side of the voltmeter to ground, as shown.
5. Start the engine and take voltage readings at 1500 and 2500 rpm. Take the readings quickly to avoid damaging the alternator. Compare the readings to the proper specifications for your make of alternator below:

	Output	
Alternator	*1500 rpm*	*2500 rpm*
Denso	18v	31v
Kokusan	22v	40v

Stator Coil Test

1. Remove the alternator stator.

ROTOR TEST



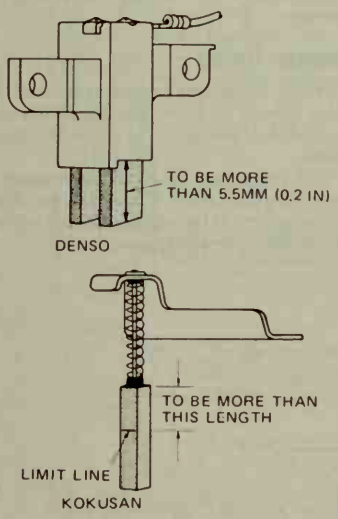
1. Check the resistance between each of the rotor slip-rings and the rotor core. In each case, resistance should be infinite.

Checking for continuity between the rotor slip-rings

If it is not, the slip-ring(s) are grounded, and the rotor must be replaced.

2. Check the resistance between the slip-rings themselves. It should be 10.5–11.5 ohms for the Denso rotor, and 4–5 ohms for the Kokusan unit. If the

Rotor resistance test points



resistance is not close to this value, the rotor must be replaced.

BRUSHES

Check the rotor brushes for condition. Replace them if cracked or damaged.

Check the brushes for wear. The brushes for the Kokusan alternator have the wear limit marked right on the brush, and they should be replaced if worn to near the line.

If you have a Denso alternator, the

Carbon brush wear limits

length of the brushes, when new, is 14 mm (0.6 in.). Remove the brush holder from the stator assembly, lift up the spring, and measure the length of the brush protruding from the holder. If it is less than 5.5 mm (0.22 in.) on the GT550, or less than 7 mm (0.28 in.) on the GT380, the brushes should be replaced.

Clean the rotor slip-rings with a solvent before installation.

GT750

The GT750 uses a Denso alternator. Procedures for testing the electrical components are therefore the same as described above for the GT550 and GT380. Note the exceptions below:

1. When performing the alternator no-load test, observe the cautions outlined above. Disconnect the regulator; disconnect the red lead coming from the rectifier and connect the lead to one side of a voltmeter and the other side of the meter to ground. By-pass the fuse in the starter switch relay lead. With a suitable length of wire, connect the green lead coming from the alternator directly to the battery positive terminal. Then perform the test as described for the GT380 and GT550. Specifications are as follows:

1500 rpm above 16v
2500 rpm above 27v

2. After removing the brush holder, lift up the spring so that the brush is free, and measure the length of the brush protruding from the holder. Brush length, when new, is 12.5 mm (0.49 in.); replace if measured length is less than 5.5 mm (0.22 in.).

IGNITION CIRCUIT

Coil

1. If an electrotester is available, check each coil with it. A good coil should be able to produce a constant spark over a 6 mm (0.24 in.) gap for a period of about 5 minutes.

2. The coils can also be checked with an ohmmeter. Measure the resistance of the primary coil by connecting the meter to the orange coil lead and the contact breaker lead (white, yellow/black, or black) for each ignition coil. Primary coil resistance should be 4–6 ohms. If the resistance reads infinity, the coil has an internal broken wire, and must be replaced.

3. Check the resistance of the secondary coil by connecting the ohmmeter to the orange lead and the high-tension lead (not including the spark plug cap). Resistance should be 15–25,000 ohms. If much lower than this figure, the coil has a short circuit; if much higher, there is an open circuit in the coil. In either case, replacement is the only alternative.

Condensers

Check the capacitance of each condenser with an electrotester if one is available. It should be 0.16–0.20 mfd for each one. Replace the condensers if the reading falls short of this value.

STARTER MOTOR

GT550, GT750

REMOVAL

GT550

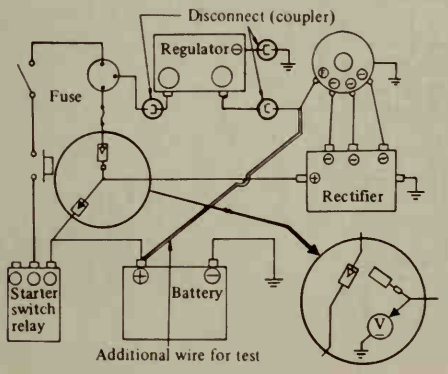
1. Remove the exhaust system. Drain the transmission oil.

2. Remove the right-side crankcase cover and the clutch assembly. Refer to "Engine and Transmission".

3. Unbolt and remove the starter motor cover from the bottom of the crankcase. Disconnect the motor lead. Pull off the gears, and take the starter motor out of the housing.

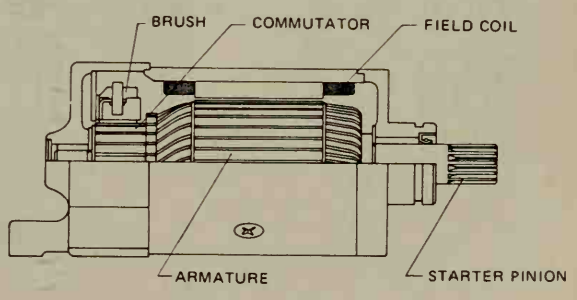
GT750

1. Remove the gas tank and the carburetors.



2. Disconnect the lead from the starter relay.

3. Remove the starter clutch cover.
NOTE: *The contact breaker assembly need not be disturbed.*



4. Drain the cooling system. Loosen the by-pass hose clamp, then take off the hose.

5. Remove the starter motor cover. Remove the by-pass hose junction from the crankcase.

6. Remove the starter motor securing bolts, then move the motor toward the

Alternator no-load test (GT750)

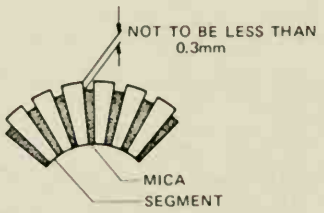
Starter motor cutaway view

clutch side of the engine, and remove it from the crankcase housing.

INSPECTION

1. Before disassembling the motor, check for lateral play of the armature shaft. Play should be very slight (0.2 mm; 0.008 in.).

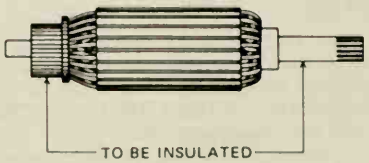
2. If play of the shaft is evident, it is indicative of a worn bush or bushes.



3. Disassemble the starter motor by removing the through-bolts. Take off the commutator end plate and the drive side end plate. Note the location of all thrust washers behind the plates.

4. The bushes are located in the end plates. Check their condition. Note any cracks or heavy scoring on the bushes. If the armature has grounded out against the field coils, this will be very evident by score marks on the armature and coils; this condition is almost always due to worn bushes, so replace them. The bushes can be driven out with a suitable drift, and new units pressed in. Lubricate the bushes with a bit of grease after installation.

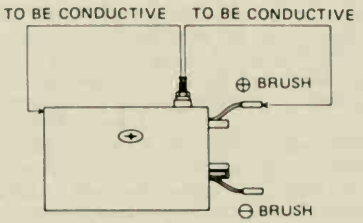
5. Clean off the commutator surface with some solvent.



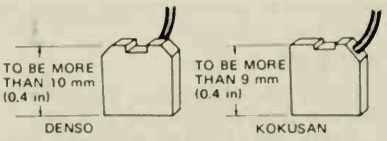
6. Check the depth of the mica undercut on the commutator. Minimum acceptable depth is 0.2 mm (0.008 in.) on the GT750, and 0.3 mm (0.012 in.) on the GT550.

If the undercut is less than these amounts, use a small, thin file or a piece of hacksaw blade to increase the undercut. The standard depth is 0.05–0.8 mm (0.02–0.03 in.). Clean the commutator very thoroughly after cutting.

Starter motor commutator mica undercut



7. With an ohmmeter or continuity light, check for continuity between the commutator and the armature shaft. If there is continuity, the commutator is grounded, and the armature must be replaced.



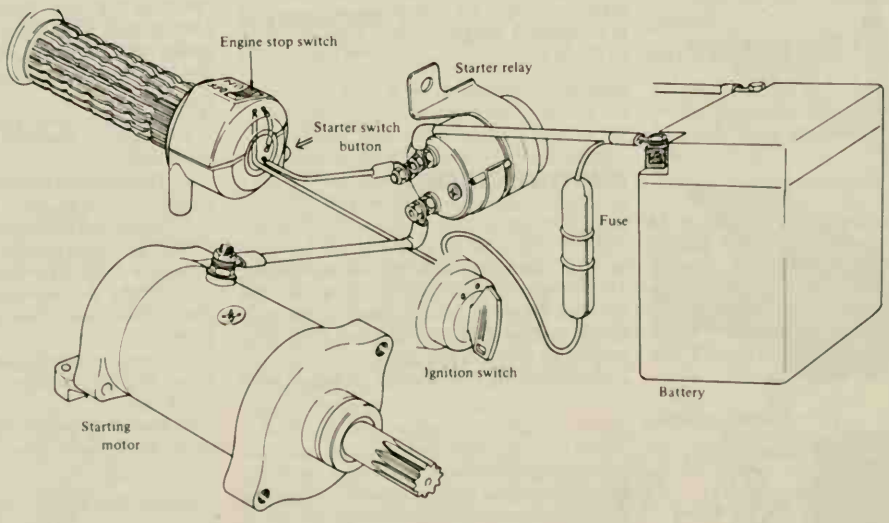
Commutator ground test

8. Check for continuity between the starter motor terminal and the positive brush as illustrated; then check for continuity between the terminal and the field coils. In both cases, the test should show continuity.

9. Check the brushes for wear or cracks. Compare the brush length with the replacement limits given in the illustration.

Field coil and brush tests

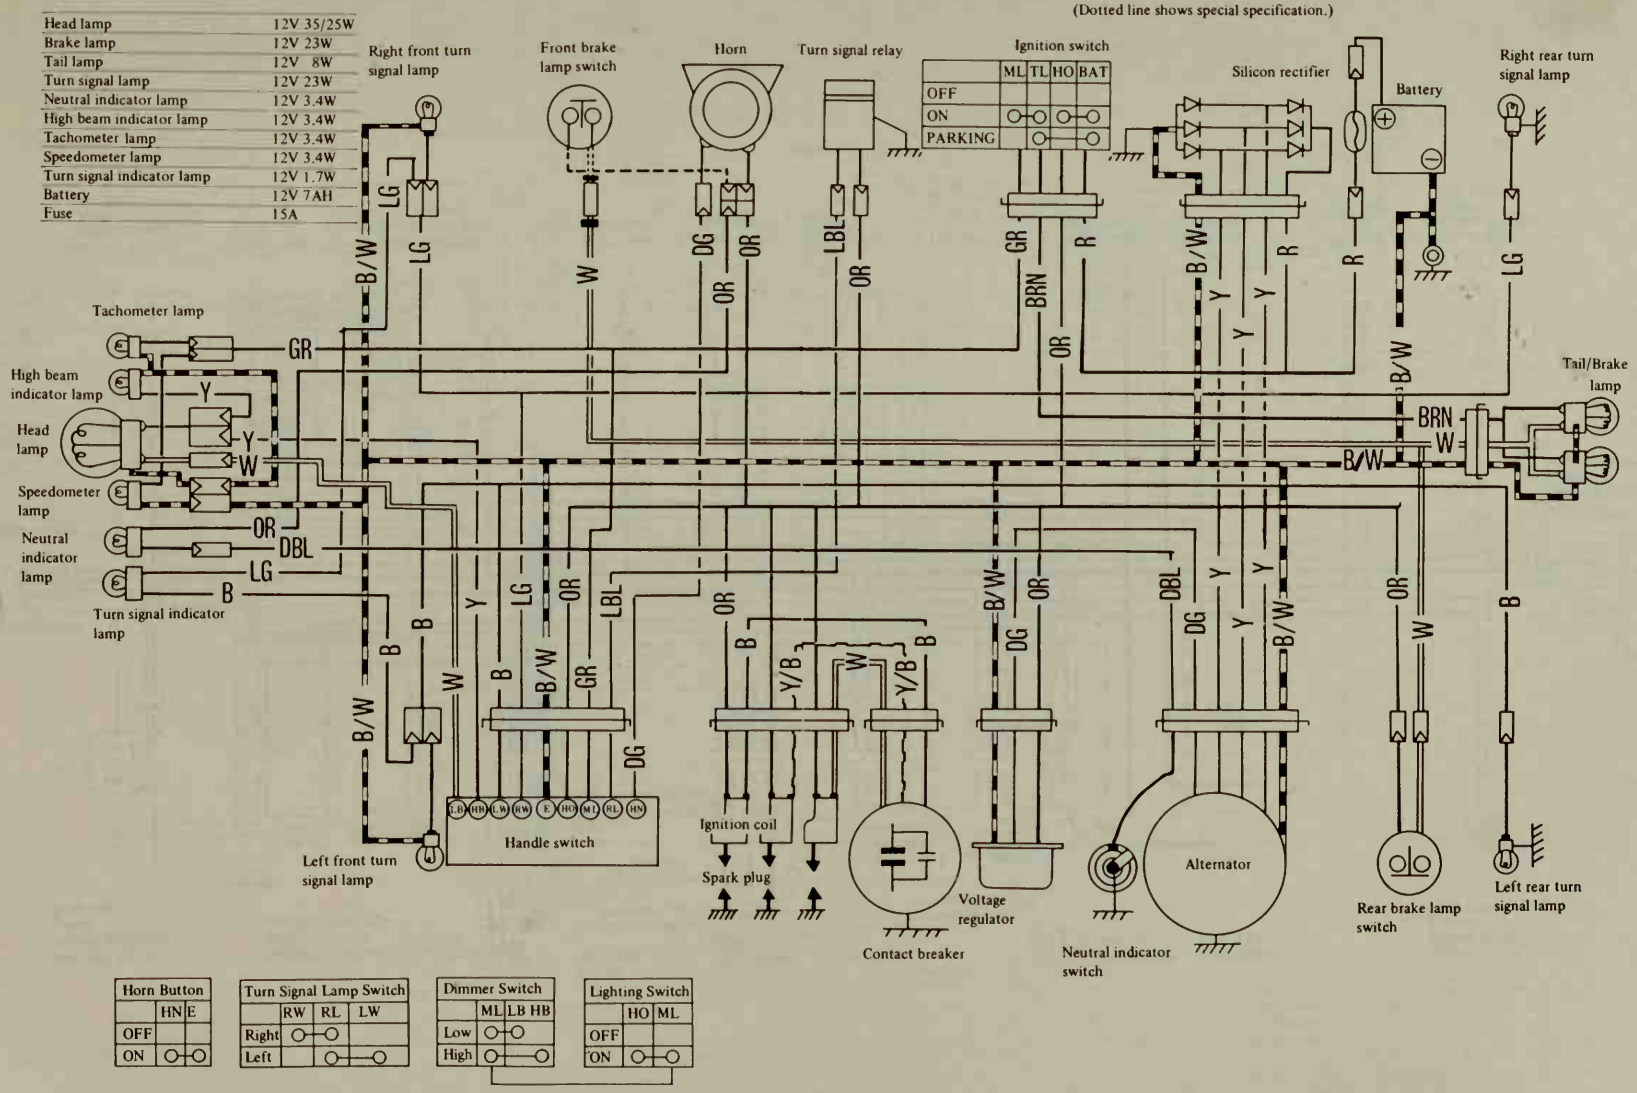
Carbon brush wear limits



ASSEMBLY AND INSTALLATION

Assembly and installation are accomplished by reversing the above procedures.

Starter Relay



When the starter button is pushed, the relay should be heard to click. If the relay is doubtful, by-pass it to see if the starter works.

The relay can be fixed sometimes by removing the cover. Check the condition of the points. If burnt, clean them off with emery cloth or sandpaper.

CHASSIS

WHEELS, HUBS, AND BRAKES

Removal and Installation

FRONT

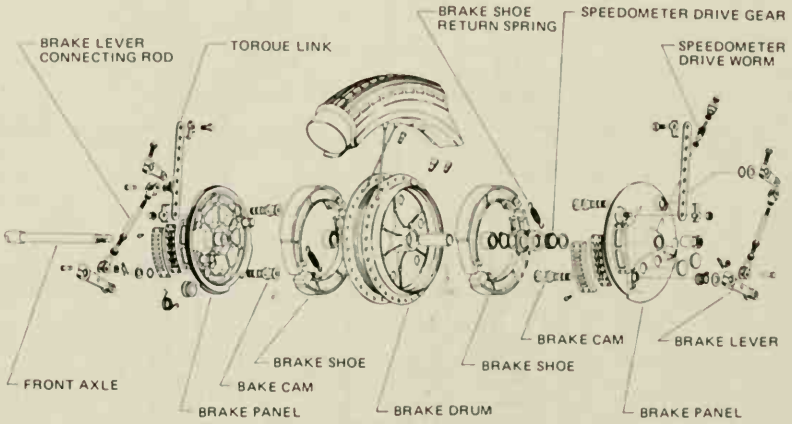
Drum Brake

The front drum brake is a four-leading shoe unit on the GT550 and GT750, and a twin-leading shoe brake on the GT380.

1. Support the front end of the machine well off the ground.
2. Disconnect the brake cable(s) at the hub.
3. Remove the brake anchor bolt(s) which secure the brake anchor(s) to the sliders.
4. Disconnect the speedometer cable at the hub. Loosen the axle nut.
5. Remove the axle holder capnuts, take off the caps, and remove the front wheel from the forks.
6. Installation is the reverse of the removal procedure. Refer to the "Torque Specifications" chart at the end of this section for the proper tightening torque for the nuts and bolts.

Disc Brake

1. Support the front end off the ground.
2. Disconnect the speedometer cable at the hub.
3. Remove the axle holder capnuts, remove the caps, and remove the front wheel from the forks.
4. Installation is the reverse of the removal procedure. Refer to the "Torque Specifications" chart at the end of this section. for the correct torque values.



REAR

1. Remove the chain guard.
2. Disconnect the rear brake cable at the hub.
3. Disconnect the brake anchor on the brake hub.
4. Remove the axle nut cotter pin, and loosen the axle nut.
5. Loosen each of the chain adjuster bolts as far as possible.
6. Remove the rear axle clamp bolts.
7. Move the wheel forward as far as possible, then disengage the drive chain from the sprocket.
8. Pull the wheel back and remove it from the frame.

Drum Brakes

INSPECTION

1. Check the condition of the brake linings. If the linings are scored or oil-impregnated, they should be replaced.
2. Clean the linings with sandpaper, and wash them off with a solvent. Use the sandpaper to break the glaze on the linings.
3. Check the condition of the brake drum, noting any scoring. Clean off the drum surface with sandpaper as used on the linings, and clean it thoroughly with a solvent afterward.

Front wheel assembly—exploded view

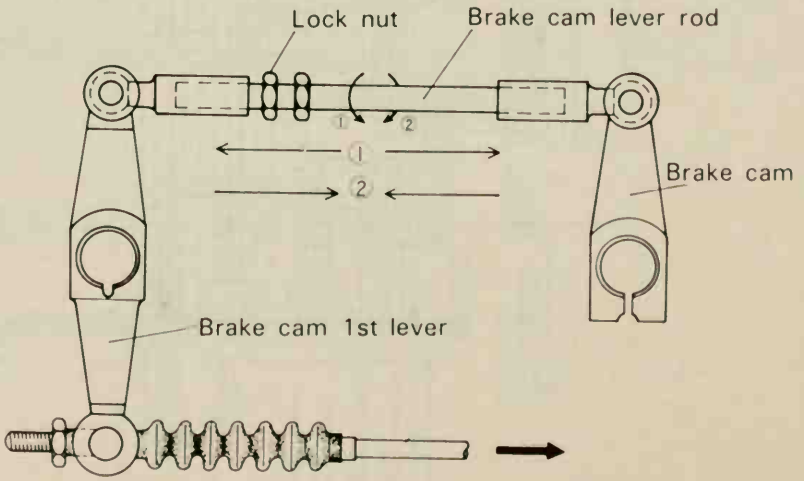
4. If the drums are scored or if they are warped (as indicated by an on-off-on feeling when the brake is applied), they can be turned down on a lathe.
5. Measure the diameter of the brake linings installed on the backing plate. Check the diameter obtained against the replacement limit shown below.

NOTE: *When measuring the diameter of the linings installed on the backing plate, be sure that the brake cams lie flat.*

6. Measure the diameter of the brake drums. Check the reading obtained against the wear limits given below.

Brake Replacement Limits

Diameter	*GT380 mm (in.)*	*GT550, GT750 mm (in.)*
Brake shoe		
Front	176 (6.93)	194 (7.64)
Rear	176 (6.93)	176 (6.93)
Brake drum		
Front	180.7 (7.11)	200.7 (7.90)
Rear	180.7 (7.11)	180.7 (7.11)



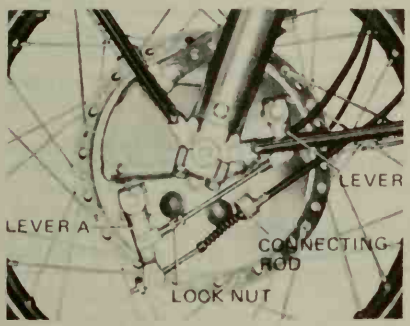
7. Check the condition of the brake return springs, and replace them if they are badly rusted or corroded, or if the ends of the springs are twisted or damaged.
8. The brake cams may be lubricated after removing the brake shoes, removing the brake lever pinch-bolts, and carefully pulling the levers off the splined cams; the cams are then tapped out of the brake backing plate using a soft-faced mallet.
9. Clean off the brake cams with a solvent; remove any rust with emery cloth or sandpaper. Lubricate the cams with chassis grease, and install.

ADJUSTMENT

Adjustment of the brake rods will not be necessary unless the brake hub has been completely disassembled.

GT380

The GT380 drum front brake is a twin-leading shoe unit. To adjust the brake rod, loosen the locknut on the rod; turn the rod in the direction "1" shown in the illustration. Pull the handlebar brake lever full on. This will mean that one shoe is contacting the brake drum. Now turn the rod

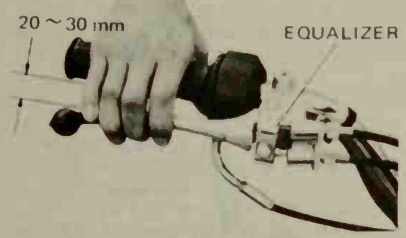


GT380 drum brake adjustment

in the direction "2", opposite the way you turned it first, until the other shoe contacts the drum, at which time it will no longer be possible to turn the rod. Tighten the locknut. Set the handlebar brake lever to give about 1 in. (20–30 mm) of play before the shoes contact the drum.

GT550, GT750

Drum front brakes on these machines are four-leading shoe units. Each set of shoes must be adjusted individually.



To adjust, loosen the brake rod locknut, then turn the brake rod to shorten the distance between brake levers "A" and "B"

GT550, GT750 drum brake adjustment procedure

in the illustration. The rod should be turned so that it will be threaded into lever "A".

Push lever "A" so that the shoes contact the drum; hold this lever in position with your hand, and with your other hand, unscrew the brake rod from lever "A" until you feel that the shoe controlled by lever "B" has contacted the brake drum. The rod will no longer be able to be turned by hand at this point. Tighten the locknut.

Brake lever play before brakes contact the drum

Repeat the procedure with the other set of brakes.

Then set the brake lever at the handlebar so that the lever will move about 1 in. (20–30 mm) before the brakes contact the drum.

Disc Brakes

Observe the following cautions when attempting work with hydraulic disc brake fluid:

a. Use DOT 3 or DOT 4 fluid only.

b. Never mix fluids from different manufacturers.

c. When adding fluid to the master cylinder, use fluid from a tightly sealed container only. Do not use old fluid, or fluid which has been stored for even a short time in an unsealed container.

d. Do not use fluid which has come in contact with water, or which has been left open to humid air.

e. Do not allow brake fluid to come into contact with painted surfaces or plastic parts.

INSPECTION

Perodically check the hydraulic system, noting the following points:

1. The master cylinder fluid level should be approximately at the level mark. On "L" and later models, a "see-through" reservoir is fitted, so removing the cap and diaphragm to check fluid level is not necessary.

2. As the brake pads wear, the fluid level will drop slightly. It should not be necessary to add fluid, as the level will rise when new pads are installed.

3. If the fluid level does drop well below the level mark, carefully check the system for leaks. Check the hoses for abrasions or cracks, and the caliper(s) for leaky seals.

4. Keep an eye on the pad wear, and replace them when they are worn to near the red limit line. See below.

5. Check that the hoses do not contact the frame or forks at any places except their fastening points.

BLEEDING

This procedure should be necessary only if any of the brake components have been disassembled, or if the brake level travel is excessive or feels spongy.

On the GT750, bleed one caliper at a time.

1. Remove the dust cap from the caliper bleed valve, and fit a suitable piece of plastic or rubber hose to it. A transparent hose is preferred.

2. Arrange the hose so that it loops upward, then immerse the other end in a clean container with a couple of inches of new brake fluid in it.

3. Squeeze the handlebar lever several times, then hold it hard on.

4. Open the bleed valve ½ turn while holding the lever on. The lever will be pulled to the twist-grip as the fluid is expelled. Hold the lever in position against the twist-grip; do not release it.

5. Tighten the bleed valve; release the lever; then repeat the procedure until all air has been expelled from the lines.

NOTE: *Keep track of the fluid in the reservoir during the bleeding operation, and refill it as necessary.*

6. After bleeding is complete, fill the reservoir to the proper level, and refit the diaphragm and secure the cap tightly.

PAD REPLACEMENT

1. Remove the front wheel.

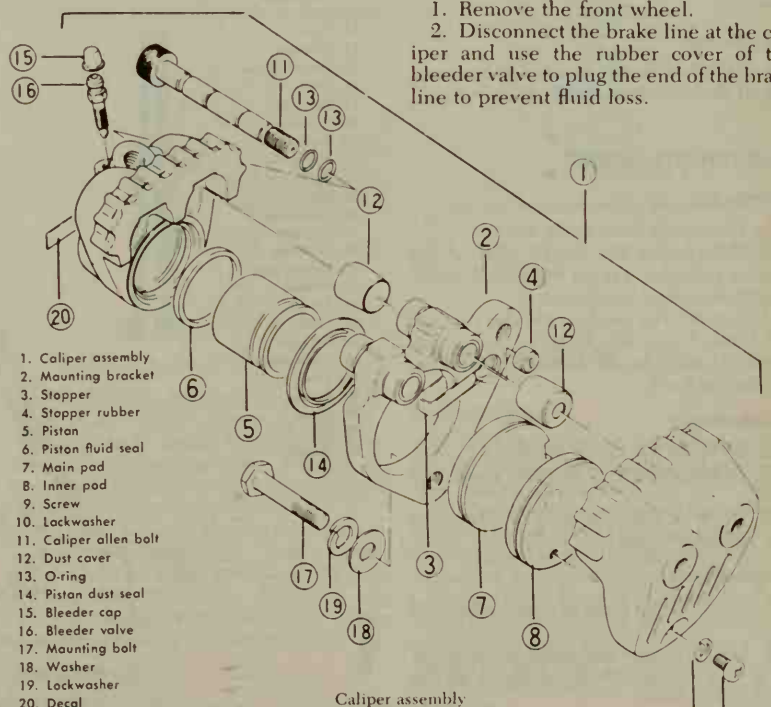
2. Remove the securing screw and take out the inner brake pad.

3. Squeeze the brake lever and remove the main pad. On installation, lightly coat the sides and back of the replacement main pad with the special grease which is supplied with the pads. Do not use common grease for this purpose.

4. Open the bleeder valve slightly to relieve the pressure, then push the piston in all the way and close the valve.

5. Insert the main pad making certain that the groove is properly aligned with the positioning pin.

6. Install the inner pad, apply a small amount of thread locking compound to the securing screw, and tighten it firmly.



7. Install the front wheel.

CALIPER

Removal

1. Remove the front wheel.

2. Disconnect the brake line at the caliper and use the rubber cover of the bleeder valve to plug the end of the brake line to prevent fluid loss.

Caliper assembly

3. If the caliper is to be disassembled after removal, loosen the two caliper (allen) bolts now.

4. Remove the mounting bolts and take off the caliper.

Disassembly

1. Remove the allen bolts and separate the caliper halves.

2. Remove the inner pad securing screw and remove the pad.

3. Remove the main pad.

4. Remove the piston dust seal. Use compressed air applied to the brake line connection to force out the piston.

5. Remove the piston seal from the caliper taking care not to scratch the caliper walls.

Inspection

1. Clean all metal parts in new brake fluid only. Do not use solvents.

2. Measure the diameter of the piston and the inside diameter of the caliper bore, and compare the readings to the standard specifications and wear limits.

3. Check the sides of the piston and caliper bore for scuffing and replace the components if damaged.

Assembly

The use of new fluid seals, dust seals, and o-rings is recommended.

1. Coat the piston seal with new brake fluid and insert it into the caliper, ensuring that it is properly seated.

2. Lightly lubricate the caliper walls and sides of the piston with new brake fluid and install the piston in the caliper, being careful that the seal is not damaged when installing the piston.

3. Caliper allen bolts must be lubricated with special Suzuki grease before installation. The remainder of the procedure is the reverse of disassembly. Be sure the allen bolts' dust covers are in place.

Installation

Installation is the reverse of removal. Bleed the system as outlined above.

MASTER CYLINDER

Removal

1. Disconnect the brake switch.

2. Disconnect the brake line at the master cylinder, taking appropriate precautions against fluid spillage.

3. Loosen the master cylinder cap and the brake lever bolt. Remove the mounting bolts and take off the master cylinder. Drain the fluid.

Disassembly

1. Remove the brake lever.

2. Remove the boot stopper, plate, and boot.

3. Remove the snap ring and take out the piston assembly.

Inspection

1. Clean metal parts in new brake fluid only.

2. Clean piston and cylinder bore for wear against specifications given in the Disc Brake chart.

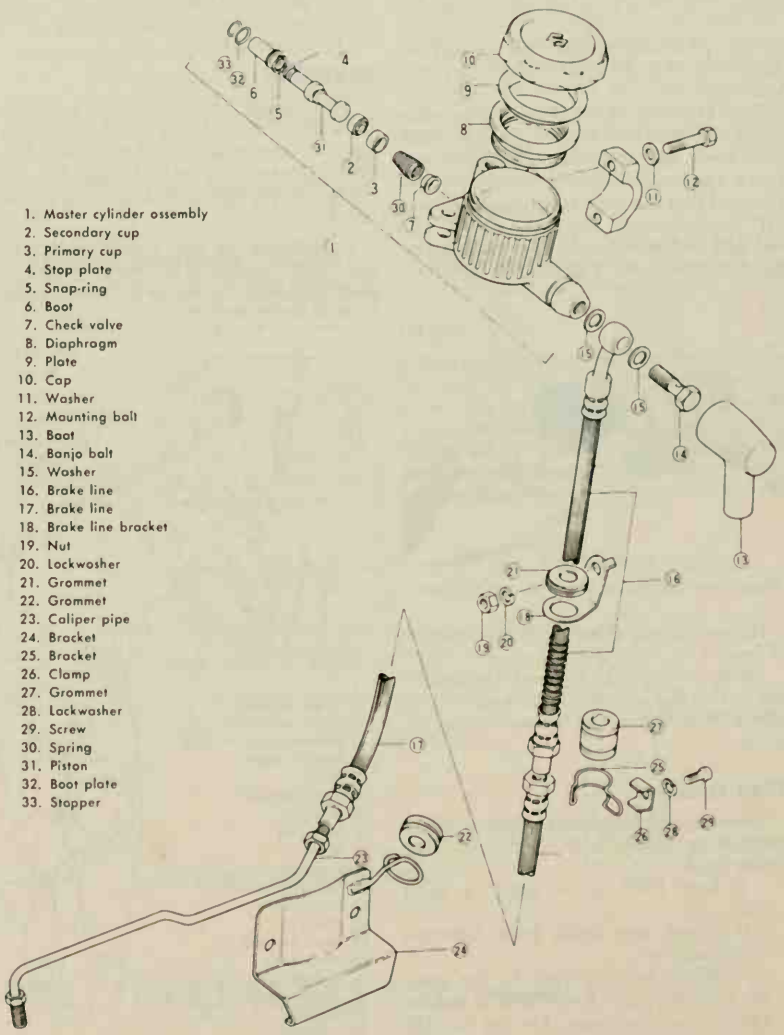
3. The use of new rubber parts such as the primary and secondary cup is recommended.

Assembly and Installation

1. Assembly is the reverse of disassembly. Lubricate all parts with new brake fluid before installing.

2. Bleed the system.

BRAKE DISC



1. Check disc thickness and run-out and compare to the standard specifications.

2. Replace the disc if worn or scored. If run-out is excessive, first check that the wheel bearings are not worn.

3. If the disc is removed, tighten bolts to 11–18 ft lbs. when installing.

Master cylinder assembly

HUBS

1. After removing the brake drum(s) from the hub on drum brake-equipped wheels, the wheel bearings can be removed for inspection and lubrication.

2. The bearings should be packed every 12,000 miles. Use a good grade of bearing grease.

3. The grease is kept in the hub by seals on either side of the bearing assembly. These seals should be replaced if they are removed.

4. On front wheels, remove the speedometer drive assembly from the hub, and the bearing retainer circlip.

5. On rear wheels, remove the final drive sprocket assembly. This is simply pulled off the hub. It is not necessary to unbolt the sprocket from the sprocket holder.

6. Drive out each bearing from the hub by reaching through the hub and tapping the bearing with a suitable drift.

Note that the sprocket assembly is also fitted with a bearing.

7. Thoroughly clean the bearings in solvent and dry them with compressed air. Check each bearing for excessive looseness of the balls or play of the inner bearing race.

Place the bearing on a flat surface, hold the outer race firmly in place, and then attempt to move the inner race about. If you can, the bearing is too worn to be serviceable, and both bearings in that wheel should be replaced.

8. Inspect the bearings for visible wear or scoring or for the presence of rust. Note any dented or partially flattened balls. Replace any damaged or doubtful bearings.

7. Pack each bearing with bearing grease. When installing them, use the axle to center the bearing in the hub. Install one bearing, put a bit of bearing grease into the hub cavity, then install the spacer and the other bearing. Check the operation of the bearings. Install new grease seals.

8. The sprocket is removed by bending down the locktabs, removing the nuts, and pulling the sprocket off the holder. When installing, be sure that the nuts are tightened evenly.

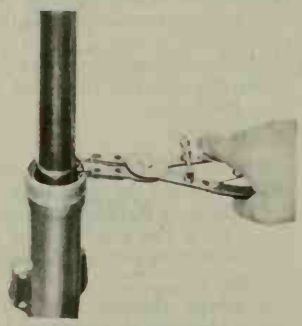
9. Check the condition of the damper rubbers. Replace them if they are badly torn or otherwise damaged.

FRONT FORKS

The front forks on all three models are similar. On "L" and later models, the rubber fork boots were removed, and the fork sliders topped off with a dust seal.

Removal and Disassembly

1. Support the front end well off the ground. Remove the front wheel and fender.



2. On disc brake models, unbolt the caliper(s) from the fork slider(s).

3. Drain the oil from each fork leg, pumping the slider up and down to insure that all the oil has been removed.

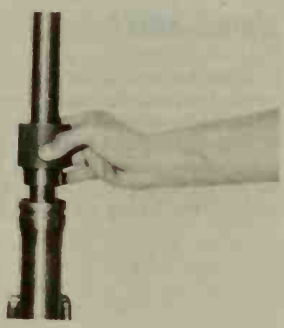
4. Remove the fork capnut; remove the allen bolt at the very bottom of the fork slider.

5. Lift up the fork boot or the dust seal to gain access to the circlip at the top of the slider. Remove the circlip with a pair of snap-ring pliers. Then remove the slider from the fork leg.

6. Loosen the upper and lower triple clamp pinch-bolts, and pull down on the fork leg to remove it from the machine.

Removing the fork slider circlip

Inspection



1. Check the condition of the fork tubes. Bent tubes must be replaced unless a press is available to straighten them.

2. A fork tube which has been kinked or creased must always be replaced.

3. Check the surface of the fork tube in the area of fork slider operation and insure that it is free of rust or corrosion. Remove any foreign matter from the tube surface with emery cloth or sandpaper. This should not be necessary if the tubes are chromed ("L" and later models).

4. Check the fork tube for scoring or wear in the area in which the sliding bushing operates. Remove any scoring with emery cloth or sandpaper, then check the movement of the sliding bushing on the fork tube.

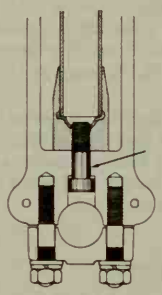
5. Inspect the inner surface of the sliding (flanged) bushing noting any wear or score marks. The bushing should be a close sliding fit on the fork tube: but neither too loose nor too tight. Replace the bushing if scoring is evident or if the fit on the fork tube is very loose.

Installing the fork slider oil seal

6. Check the fork springs for fatigue or a collapsed condition. Both springs should be the same length. If they are not, replace both.

7. Check the condition of the spring seat and replace it if bent or worn.

Installation



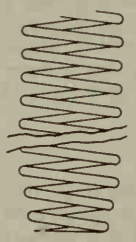
1. Clean all metal components thoroughly in a solvent, then lubricate them prior to assembly.

2. New fork slider oil seals must be used. Install the seals in the sliders as shown. They should be installed after the slider has been positioned on the tube since this will help center the seal.

3. The O-rings on the fork capnuts should be replaced if they show signs of age or wear.

4. Assembly is the reverse of the disassembly procedure. Note the following:

When installing the fork tubes in the triple clamps, make sure that the top of the tube is flush with the top surface of the upper triple clamp. Lock the tube in place by tightening the upper and lower triple clamp pinch-bolt gradually.



Slider allen bolt in position

When replacing the fork slider allen bolt, push the slider up so that it is "bottomed", then tighten the bolt.

When refitting the fork springs, note that the tapered end of the spring faces *down* (toward the spring seat).

Add the correct quantity of oil to each fork leg, and refit the capnuts.

Proper installation of the fork spring

Be sure that all nuts and bolts are firmly tightened.

STEERING STEM

Inspection

1. With the front wheel off the ground, the front forks should swing freely to either side when released.

2. Check the movement of the forks by turning them slowly lock-to-lock. Note any resistance, rough movement, noise, or halting action while moving the forks.

3. Grasp the forks at the bottom of the sliders and attempt to move them back and forth in line with the machine. There should be no play at all. If play exists, the steering stem bearings are in need of adjustment.

Checking steering stem bearing adjustment

4. Note that a squirrelly feeling in the handling of the machine at low speeds may be due to the steering stem bearings being too tight. It may also be due to low tire pressure, so check that.

5. If the forks have movement in line with the machine, the bearings are too loose, and the adjustment nut should be tightened.

6. Any unusual noise or balky movement of the forks is probably due to worn or damaged balls or races, and the steering stem should be removed and these parts checked.

Adjustment

1. Remove the instruments, handlebars, etc.

2. Loosen the 3 upper triple clamp pinch-bolts. Remove the fork crown nut. Strike the underside of the triple clamp with a soft-faced mallet and remove it.

3. Remove the dust seal from the steering stem.

4. With a suitable wrench, or with a blunt punch and hammer, tighten or loosen the steering stem nut as needed to achieve proper bearing adjustment.

5. As described above, the forks should swing freely from side-to-side, and the movement should be smooth.

Removal

1. Support the front wheel well off the ground, and remove the wheel, fender, brake calipers (disc brake), front forks, instruments and handlebars. Remove the headlight assembly and the fork ears.

2. Loosen the rear pinch-bolt on the upper triple clamp; remove the fork crown nut.

3. Hit the underside of the triple clamp with a soft-faced mallet and remove it.

4. Remove the dust cover. Begin loosening the steering stem nut, and, as it is loosened, grasp the underside of the lower triple clamp, holding it in place until the nut is removed from the steering stem.

5. After the nut is removed, carefully lower the steering stem and remove it from the frame.

Inspection

1. Wash all of the bearing balls in solvent to remove the old grease.

2. Clean off the bearing races.

3. Check the condition of the balls. Note any rust, pitting, dented balls, or scoring.

4. Check the condition of the ball races. The race surface must be smooth. Note any cracks, rust, denting, or a rippled surface.

5. If any damage is evident, balls and races should be replaced as a set.

6. Smear the surface of the lower race with bearing grease, and embed the balls in the grease to hold them in place during installation.

Assembly

Reverse the removal procedure. Hold the steering stem in place on the frame; make sure that all of the balls are in place, then screw on the nut. Adjust the bearings as described above.

REAR SHOCK ABSORBERS

The shock absorbers are sealed units. If they fail to function properly, or leak oil, they must be replaced.

SWING ARM

With the back wheel supported off the ground, check the swing arm for lateral play. There should be none.

If the swing arm bushings are worn (in which case lateral play will be evident), or if the swing arm is cracked or bent, remove the swing arm for service.

1. Remove the rear wheel assembly.

2. Remove the chain guard; unbolt the shock absorbers from the swing arm.

3. Remove the swing arm spindle nut and pull out the spindle; remove the swing arm from the frame.

4. Inspect the bushings for wear and replace as necessary.

5. Installation is the reverse of the removal procedure.

MAINTENANCE

NOTE: *Common maintenance procedures are explained in detail in the "General Information" section.*

LUBRICATION

SAE 10W-40 motor oil, service rating "SE" or "SF" is recommended for all temperatures.

Checking Oil Level

1. The 750/850 has a wet-sump lubrication system, all of the oil being contained in the crankcases.

2. Allow the engine to run for several minutes before checking the oil level.

3. A sight glass or inspection window is provided on the right side of the engine just below the kickstarter. With the machine parked on level ground and on the center stand, and the engine shut off, check the oil level by reference to the marks inscribed on the crankcase. Oil level should be between the "L" and "F" marks.

4. If the oil level is at or near the lower level mark, add enough oil to bring it up to the "F" mark, but do not overfill the crankcase.

Changing Oil

1. The recommended oil change interval is 1,500 miles or 3 months, whichever comes first.

2. Oil should be changed when the engine is warm. This ensures more complete draining and makes it more likely that the oil will carry off any particulate matter with it.

3. Place a suitable container (about 4 qt capacity) beneath the engine and remove the drain plug. Allow the oil to drain for several minutes. Check the condition of the drain plug gasket and replace it if necessary. Refit and tighten the drain plug securely.

Oil level sight glass

4. If the oil filter is to be replaced, see "Oil Filter," below.

5. If only the oil is being changed, add about 2.8 l (3.0 qt) of oil to the crankcase. If both oil and filter are being changed, add about 3.4 l (3.6 qt).

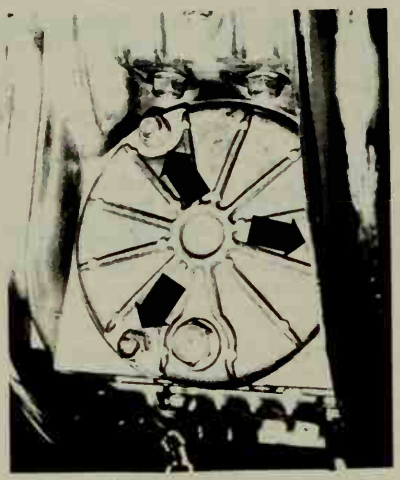
These amounts are approximations. Make final determination by checking the oil level at the inspection window, and top up to the upper limit line. Start the engine and allow it to idle for about 10 seconds. Shut it off and let it sit for another minute. Check the oil level at the inspection window. Top up the crankcase, if necessary, so that the level is at or near the "F" mark. Do not overfill.

Start the engine and allow it to idle for about 10 seconds. Shut it off and let it sit for another minute. Check the oil level at the inspection window. Top up the crankcase, if necessary, so that the level is at or near the "F" mark. Do not overfill.

Oil Filter

1. The oil filter should be changed at every other oil change, or every 3,000 miles.

2. After draining off the crankcase oil, place a drip pan or container beneath the oil filter cover at the front of the engine.



3. Remove the filter cover bolts and take off the cover. Pull the old oil filter.

4. Install the new filter.

5. Before refitting the filter cover, check the condition of the O-ring and replace it if it is knicked or otherwise damaged. Be sure that the mating surface is clean. Lightly oil the cover O-ring before refitting the cover.

Crankcase drain plug

Oil filter cover bolts

6. Tighten the cover bolts gradually to a torque of 4.3-5.8 ft lbs.

Filter Screen

The oil filter screen should be cleaned every 6,000 miles, or about once a year.

The filter screen is easily reached after removing the exhaust pipes and the oil pan.

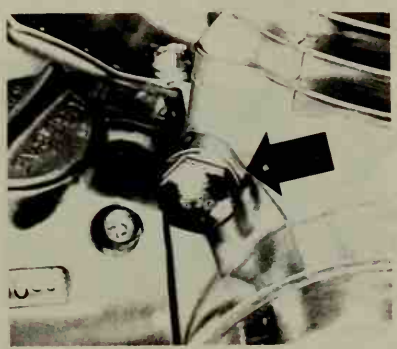
Use a new oil pan gasket on assembly. Be sure to tighten the pan bolts evenly to avoid distortion. Tighten the pan bolts to 7.2 ft lbs.

Engine Oil Pressure

1. Be sure that the engine has the proper quantity of oil (between the "F" and "L" marks on the inspection window).

2. Start the engine and run it until oil temperature reaches about 60° C (140° F).

3. Remove the oil gallery plug at the right side of the engine just below the cylinders and install the special oil pressure gauge.



4. Start the engine and run it at about 3,000 rpm while checking the gauge reading. Oil pressure should be about 1.42 psi or more (0.1 kg/cm^2).

5. If the oil pressure is below this limit, remove and inspect the oil pump internals.

6. When fitting the oil gallery plug, be sure to secure it with a non-permanent thread-locking compound. Tighten the plug securely.

Drive Shaft

The secondary drive box and the final drive box both use SAE 90 EP hypoid gear oil.

Oil pressure gauge gallery plug

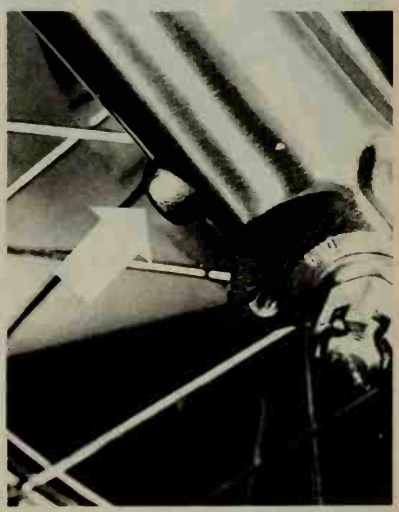
1. To check the oil levels, park the motorcycle on the centerstand on a level surface. Remove the gear shift lever and the secondary drive box cover. Remove the oil level screw. If the level is correct, oil will just begin to come out of the level hole.

To check the final drive box level, remove the level plug/filler cap. Oil should just start to come out if the level is correct.

2. To change oil in the drive boxes, run the motorcycle until operating temperature is reached.

3. Remove the gear shift lever and the secondary drive box cover. Remove the secondary drive box filler plug, drain plug, and level screw.

4. Refit the drain plug. Add SAE 90 gear oil until it begins to come out of the level screw hole. The amount is about 340–400 cc (11.5–13.5 oz).



5. The final drive box oil is changed in the same manner. Capacity is 280–330 cc (9.5–11.2 oz).

Front Forks

GS 750

1. Proper oil for the front forks is a 50/50 mixture of ATF (Automatic Transmission Fluid) and SAE 10W-30 motor oil.

2. Fork capacity is 180 cc (6.1 oz) per fork leg for all except "L" models which is 280 cc (9.5 oz) for each leg.

Front fork drain plug

3. Fork oil should be changed every 6,000 miles, or once a year.

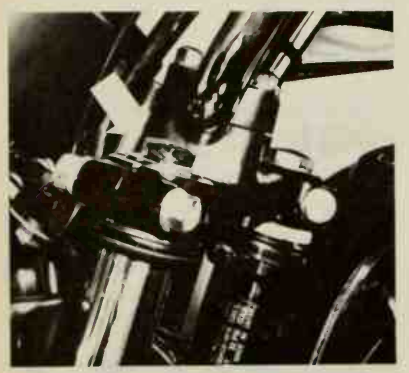
4. Place a container beneath one of the fork sliders and remove the drain plug. Pump the slider up and down until all the oil is expelled. Examine the plug gasket, then refit the plug. Repeat the procedure with the other slider.

5. Examine the drained oil. If it contains water or is exceptionally dirty, it may be that the dust covers are damaged and allowing foreign matter to get past. This will also damage fork seals quickly. Check that the dust covers are properly secured and replace them if cracked, ripped, or otherwise damaged.

6. Support the front wheel off the ground by placing a scissors jack or similar device beneath the engine.

7. Remove the handlebar clamp bolts and move the bars to one side or the other to allow access to the fork filler caps.

8. Remove the fork filler caps. Often loosening the upper triple clamp pinch bolts will make it easier to remove the caps. Since the caps are under spring tension, care should be exercised when removing them.



9. Remove the upper fork springs to facilitate the job of adding the fork oil. Add 180 cc (6.1 oz) to each leg.

10. Inspect the filler cap O-rings for damage and replace them if necessary. Fit the springs and caps, tightening them securely. Tighten the triple clamp pinch bolts if they were loosened. Secure the handlebars, tightening the forwardmost bolts first.

GS 850

Routine oil changes are not necessary on the GS 850. Refer to "Chassis" for service procedures.

Fork air pressure should be checked every 6 mos. in the following manner:

Front fork filler cap

1. Check fork air pressure every 6 mo. Make the check when the forks are "cold" (i.e. before riding).

2. The motorcycle should be on the centerstand with the front wheel off the ground.

3. Pressure is checked with a special gauge. Remove the air valve caps. Turn the valve on the end of the special tool clockwise until it locks. Then turn the other tool valve counterclockwise until it turns freely. Mount the gauge, turning the valve nut clockwise until it stops. Turn the valve on the end of the special tool clockwise until it locks. Pressure should be 8.5–17.0 psi.

4. Raise air pressure if necessary using the hand-held manual pump only. Do not use a compressed air source. Excessive pressure may blow out the fork seals.

5. Fork legs should be less than 1.4 psi apart.

Drive Chain

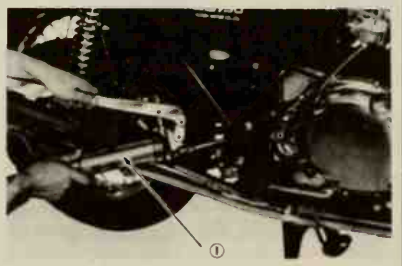
1. The drive chain is equipped with rubber O-rings between the plates to seal in the lubricant. At periodic intervals, however, some lubrication of the chain rollers is necessary.

2. About every 600 miles, clean the chain with kerosene.

CAUTION: *Do not use gasoline or any other solvents to clean the chain as the O-rings may be damaged.*

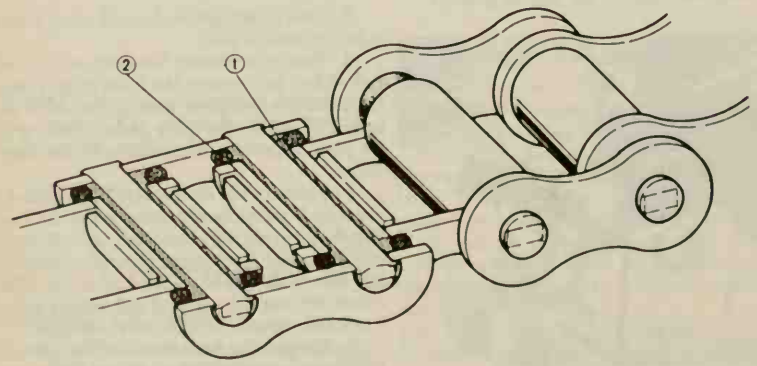
3. After cleaning and drying the chain, lubricate the rollers with 80 or 90W oil. Wipe off any excess.

NOTE: *Do not use commercial chain lubricants on the rollers, as they may cause damage to the O-rings.*



The chain O-rings can be damaged by steam cleaning, high-pressure spray, and certain solvents, keep this in mind when cleaning the motorcycle.

4. If rust is seen to develop on the rollers, lubricate them at more frequent intervals.



Chassis Lubrication

1. The swing arm pivot (750) is fitted with a grease nipple which should be lubricated with a high-quality chassis grease every 12,000 miles or 2 years.

2. Wheel and steering head bearings are lubricated with bearing grease, the service interval being 12,000 miles or 2 years.

Lubricating the swing arm

Drive chain lubricant (1) and sealing O-rings (2)

SERVICE CHECKS AND ADJUSTMENTS

Drive Chain

1. The chain should have about 20–30 mm (0.8–1.2 in.) of total up-and-down free-play measured in the middle of the lower chain run.

2. Before checking or adjusting the chain slack, the following conditions should be met:

a. The motorcycle should be placed on the center stand so that the rear wheel is off the ground,

b. The transmission should be placed in neutral,

c. The chain should be clean and well-lubricated,

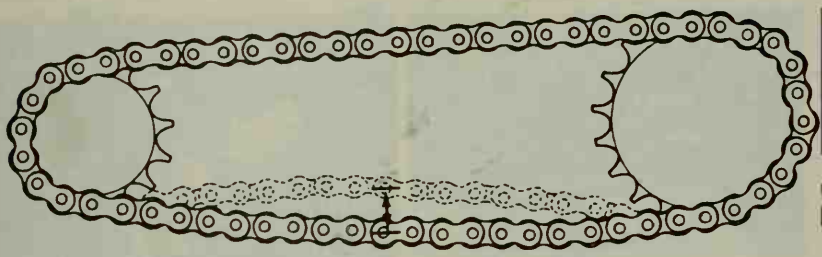
d. The chain should have been checked for any tight spots by slowly rotating the wheel and checking for variances in the chain tension at different points. If a tight spot exists, the chain tension should be adjusted to the prescribed free-play at the tight spot. Note, however, that such a condition is indicative of a worn chain and probably worn sprockets, which should be replaced as soon as possible.

3. Remove the axle nut cotter pin and loosen the axle nut several turns. Loosen the locknut on each chain adjuster bolt.

4. Turn each of the adjuster bolts in or out by equal amounts until the chain tension is approximately correct.

5. Check wheel alignment by means of the aligning marks inscribed on both sides of the swing arm. Be sure that both adjusters are lined up with the same mark on each side. If not, turn one of the adjuster bolts in or out so that alignment is achieved.

6. Tighten the axle nut and adjuster bolt



Drive chain adjustment alignment marks

nuts and check the chain tension. The chain tension should also be checked with the weight of a rider sitting on the motorcycle when it is off the center stand; the chain should still have at least ½ in. of free-play. Correct if necessary. After adjustment is correct, torque the axle nut to 62–83 ft lbs.

Fit a new cotter pin.

Clutch

1. Cable adjustment must always be maintained at the proper specification. If the cable

Drive chain free-play is measured at the middle of the lower chain run

has insufficient free-play, the clutch will slip and rapidly burn out. If it has too much play, the clutch will not completely disengage, resulting in hard shifting and creeping at stops.

2. Use the cable adjuster at the handlebar or engine to correct the amount of cable slack. The clutch hand lever should be able to be moved 4 mm (0.16 in.) measured between the lever and the holder before the clutch begins to disengage.

If clutch operation is not satisfactory after making this adjustment, proceed as follows:

3. Screw the cable adjuster at the lever in all the way, increasing cable free-play. Back off the locknut and turn the cable adjuster at the engine in as well.

4. Remove the clutch adjuster cover plate. Loosen the clutch adjusting screw locknut. Back off the adjusting screw 2–3 turns.

5. Turn the adjusting screw clockwise until resistance is felt, then turn it counterclockwise 1/4 turn. Holding the screw in this position, tighten the locknut.

6. Turn the cable adjuster at the engine out until there is about 4 mm (0.16 in.) of free-play in the hand lever. Tighten the locknut on the engine cable adjuster.

7. Make any further fine adjustments with the adjuster at the hand lever.

Clutch cable engine adjuster

Throttle Cables

A dual-cable system is used on all except models with CV carbs. The cables are equipped with adjusters at the twist grip and the linkage.

1. The cable which opens the throttles should have 0.5–1.0 mm (0.02–0.04 in.) of freeplay measured between the end of the cable sheath and the end of the adjuster.

2. The cable which closes the throttles should have zero clearance between the end of the cable and the adjuster.

CV carburetor-equipped models (GS 850GT/GN/GLT) have only a single throttle cable. Adjust it to 0.5–1.0 mm (0.02–0.04 in.) of freeplay.

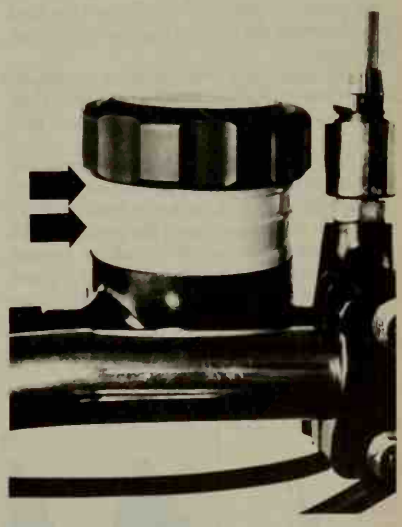
3. Use the cable adjuster at the handlebar to make and maintain this adjustment. To check that the cable has sufficient slack, start the engine and turn the forks slowly from lock-to-lock. Idle speed must not increase. If it does, it indicates that the cable has insufficient free-play, is incorrectly routed, or is binding at some point.

Brakes

FRONT

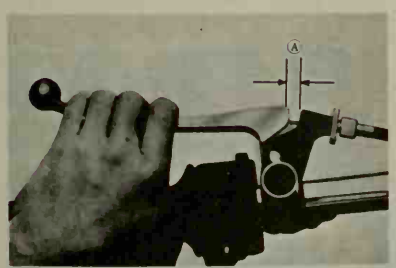
Disc brakes ordinarily need no attention other than a periodic check of the fluid level and pad wear.

1. The fluid level should be between the "Upper" and "Lower" level marks on the see-through master cylinder reservoir. If the level is below the lower level mark, add enough DOT 3 brake fluid to bring it above the mark.



NOTE: *Brake fluid is hydroscopic. It absorbs moisture. Therefore, do not use fluid from an old or unsealed container. Exercise extreme care in handling the brake fluid. It will remove paint on contact. Be sure to tighten the reservoir cap securely.*

NOTE: *The fluid level may drop slightly as the pads wear.*



2. Check brake pad wear and replace the pads as a set if either is worn to the red limit line.

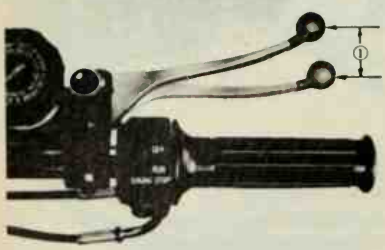
Clutch cable free-play (A) should measure about 4 mm (0.16 in.)

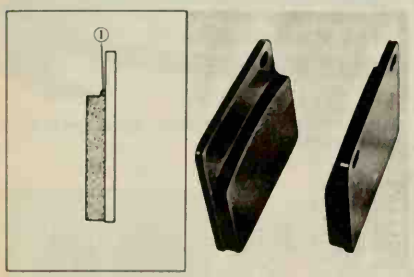


Clutch adjuster locknut (A) and adjusting screw (B)

Fixed pad (1) and piston pad (2) should be replaced as a set when worn to the red limit line (3)

3. The front brake lever should have 15–25 mm (0.6–1.0 in.) of travel measured at the tip of the lever. If lever travel is excessive, it is possible that the system needs bleeding.

The front brake lever should have 15–25 mm (0.6–1.0 in.) of movement (1)



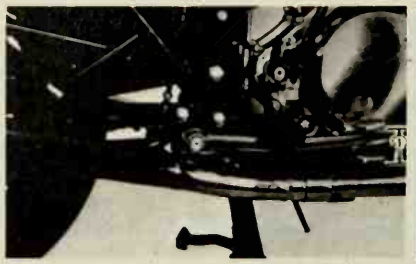
Rear brake master cylinder fluid level lines

REAR

1. Inspection procedures are virtually the same as for the front brake. Maintain the fluid level between the lines on the master cylinder reservoir.

2. To check pad wear, remove the plastic caliper cover. Pads should be replaced when they are worn to the red-marked stepped portion.

3. To adjust brake pedal height, loosen the locknut on the return stopper bolt on the footpeg bracket. Loosen the brake pushrod locknut. Turn the pushrod until the pedal is about 10 mm (0.4 in.) below the top of the footpeg rubber. Tighten the pushrod locknut. Adjust the clearance between the brake pedal arm and the stopper bolt to 0.5 mm (0.02 in.). Tighten the stopper bolt locknut. Check that the brake pedal has 9–26 mm (0.35–1.0 in.) of free-play.



Rear disc brake pads should be replaced when worn to the stepped portion (1)

Brake Light Switches

The switches should be checked for operation after the brakes are adjusted. The rear brake light switch and adjuster nut are mounted on a slotted bracket. The rear switch is adjusted by holding the switch and turning the adjuster nut to effect adjustment. Moving the switch up on the bracket allows the brake light to turn on sooner. Moving it down allows the light to turn on later. Do not turn the switch to effect adjustment as the wires will become twisted and may break.

The front switch is activated by the pressure of the brake fluid in the brake line. This switch is adjusted by loosening the two securing screws and moving the switch body.

Brake pedal free-play should be 9–26 mm (0.35–1.0 in.)

FUEL SYSTEM

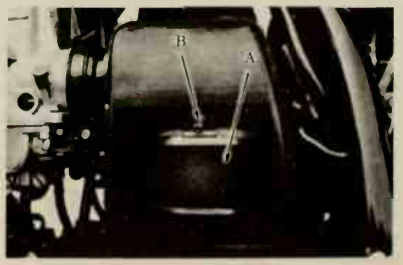
Fuel system maintenance involves cleaning the petcock fuel filter screen, cleaning the air filter, and cleaning the carburetors.

The normal service interval is 3,000 miles.

Air Filter

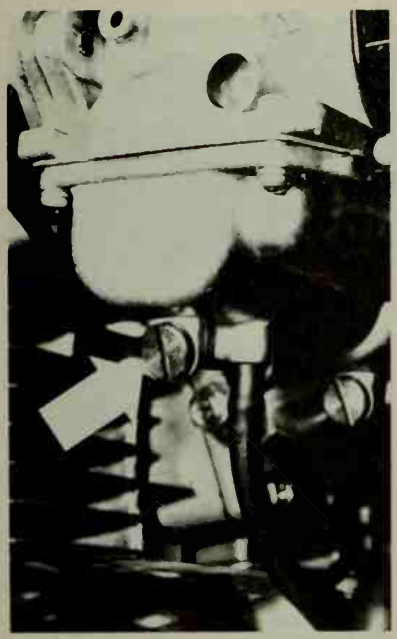
1. Remove the left side cover and the air cleaner box cover.
2. Remove the securing screw and take out the air cleaner element.
3. Remove the two element screws and separate the filter from the element.
4. Wash the filter in gasoline. Squeeze out the excess gas.

NOTE: *Remove the excess gasoline by squeezing the filter. Do not wring it out, as this risks ripping it.*



5. Soak the filter in clean motor oil. Squeeze off the excess.
6. Fit the filter to the element and reinstall.

Carburetors



1. Although major overhaul of the carburetors requires their removal as a unit, the float bowls and jets can be cleaned with the units in place.
2. Drain the fuel from the float bowls.
3. Remove the four securing screws from each float bowl and carefully lower the bowls until they are clear of the floats. It may be helpful to disconnect the overflow tubes before removal.
4. Unscrew the pilot jet. Unscrew and remove the main jet and the main jet holder/emulsion tube. Blow the jets clear, then reinstall. Clean out any residue from the float bowl. When installing, be sure to position the float bowls carefully to avoid damage to the floats. Tighten the screws gradually and evenly. Check for leaks before operating the motorcycle.

TUNE-UP

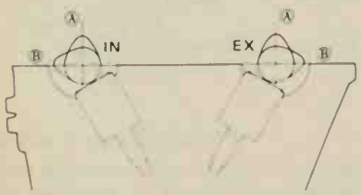
NOTE: *Common tune-up procedures are explained in detail in the "General Information" section at the end of the manual.*

COMPRESSION TEST

1. A compression check should be made before each tune-up since this will provide a general idea of engine condition.
2. It is necessary to have a gauge with a flexible hose and the proper screw-in adapter (plug holes are 14 mm).
3. The engine should be at operating temperature when checking compression.
4. Remove all of the spark plugs and fit the gauge to one of the plug holes.
5. Close the choke and hold the throttle wide open while spinning the engine with the starter motor. Note the compression reading and repeat the test with the remaining cylinders.
6. Compression may vary according to gauge tolerance and several other factors. However, it should normally be between 128 and 171 psi. All cylinders must be within 15 psi of this range and of each other.

CAM CHAIN TENSIONER

The cam chain tension is maintained automatically, and no routine adjustments are necessary once the tensioner has been set correctly.

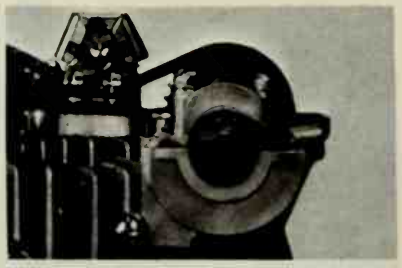


To check tensioner operation, refer to "Cam Chain Tensioner" under the "Top End" section of "Engine and Transmission."

VALVE ADJUSTMENT

Checking Valve Clearance

NOTE: *Valve clearance must be checked when the engine is cold.*



1. Remove the gas tank, the cylinder head cover, and the points cover.
2. Valve clearance is checked by inserting a feeler gauge blade between the cam lobe and the tappet shim. To do this, the cam lobes must be properly positioned or the measured clearance will be inaccurate. Refer to the illustration showing proper cam lobe positions.
3. Correct valve clearance is 0.03–0.08 mm (0.0012–0.0032 in.) for both intake and exhaust valves. The clearance is correct if a feeler gauge blade in this range is a light drag fit between the cam lobe and tappet shim.
4. Use a 17 mm wrench on the special crankshaft nut to turn the engine over (in the normal direction of rotation-clockwise as seen from the right side) until the exhaust cam for the No. 1 (left) cylinder is in the position indicated. Check the valve clearance for the exhaust valves at cylinders Nos. 1 and 2.

Rotate the engine 180°

5. After checking the clearance at the exhaust valves for cylinders Nos. 1 and 2, turn the crankshaft 180° again in the normal direction of rotation until the *intake* cam lobe of the No. 1 cylinder is at the position illustrated. Check the valve clearance of the intake valves for cylinders Nos. 1 and 2.
6. Turn the crankshaft 180° again in the normal direction of rotation until the exhaust cam lobe of cylinder No. 4 is at the position illustrated. Check the clearance of the exhaust valves of cylinders Nos. 3 and 4.
7. Turn the crankshaft an additional 180° until the intake cam lobe of the No. 4 cylinder is positioned as illustrated. Check the valve clearance of cylinders Nos. 3 and 4.

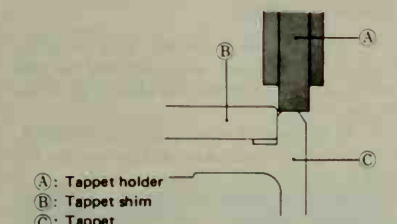
Valve clearance shim and tappet notch

Adjusting Valve Clearance

1. Adjustments to the valve clearances, if necessary, are made by replacing existing tappet shims with new ones of varying thicknesses. A special tool is necessary to hold down the tappet to remove the old shim and install the new one. In addition, a micrometer may be helpful.
2. If the valve clearance is not within the proper range when checking it as outlined above, continue slipping feeler gauges between the cam lobe and shim until the actual clearance is determined. The feeler gauge blade will be a light drag when pulled through. Record the actual clearance.
3. To remove the shims, first rotate the tappet with your fingers until the notch is accessible. Use the special tool to depress the

tappet and remove the shim with a pair of forceps.

NOTE: *Be sure that the special tool is correctly installed. It must have a firm purchase of the tappet. Refer to the illustration.*

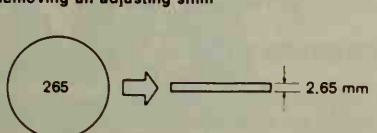


Depressing the teppet with the special tool

4. Note the thickness of the removed shim which is marked on it. "265," for example, indicates a thickness of 2.65 mm.

It is possible to use the marked thickness on the shim to calculate valve clearance provided that the shim in question is not worn. It is more accurate, however, to measure the thickness of the removed shim with a micrometer to be sure. Referring back to the actual measured clearance (Step 2, above), calculate the necessary shim thickness which will bring the valve clearance into the proper range.

The proper shim thickness is arrived at by subtracting the specified clearance from the actual measured clearance and adding or subtracting this number to the thickness of the removed shim.



If, for example, the actual measured valve clearance was 0.10 mm, shim thickness must be increased by at least 0.02 mm to bring the clearance back to the maximum allowable figure of 0.08 mm. If the thickness of the removed shim was 2.50 mm, the new shim must be at least 2.50 + 0.02 = 2.52 mm. The closest shim to this size is 2.55 mm, and this shim, when fitted, will bring the valve clearance into the specified range.

Be sure that the tappet holder tool has firm purchase on the tappet: tappet holder (A), shim (B), tappet (C)

Removing an adjusting shim

Thickness of the shims is marked on them

NOTE: *Shims are available in increments of 0.05 mm from 2.15 mm to 3.10 mm.*

If the measure clearance is too small, a thinner shim must be fitted. If, or example, the measure clearance is 0.01 mm, shim thickness must be decreased by at least 0.02 mm to bring the clearance to within specification. If the fitted shim in this instance is 2.75 mm thick, the new shim must be 2.75 − 0.02 = 2.73. The closest available shim is 2.70, and this will give a clearance which is within the tolerance range.

5. After calculating the clearance change necessary and finding the correct replacement shim, install the new shim and recheck the clearance.

NOTE: *Lightly lubricate the new shim with motor oil on both sides before fitting it and checking the clearance. Install the new shim with the thickness number facing the tappet.*

CONTACT BREAKER POINTS

Location

The points and condensers are located on the right end of the crankshaft beneath the points cover. The timing advance mechanism is fitted onto the crankshaft behind the breaker point base plate.

Replacement

1. Points sets are available complete with condensers already mounted on the breaker plate. Removal is accomplished by disconnecting the primary wires and removing the three screws which mount the breaker plate to the engine. It is of course necessary to reset the ignition timing after the new breaker plate is installed.

2. If the points are purchased separately, disconnect the primary wire at each point set, remove the securing screw, and remove the old points. When installing new points, note that the proper installation of the insulating washers at the primary terminal is critical. If improperly installed, no spark will occur. There is a small insulating tube which fits around the terminal bolt and two insulating washers, one immediately on either side of the terminal bracket. All connectors (condenser, primary wire, points spring) are made on the outersides of these washers (i.e., no connector must touch the bracket, which is a ground).

3. New points may have a protective coating on the contact surfaces to prevent oxidation. Clean off these surfaces with a non-oily solvent before attempting to start the machine.

4. If the motorcycle will not start immediately after installation of new points, check that the primary wire connections are tight, that the insulating washers at the primary terminal are properly installed, and that the contact surfaces are thoroughly cleaned.

5. Condensers are easily replaced after disconnecting the lead at the primary terminal and removing the screw which secures the condenser to the base plate.

Gapping

Periodic gapping is necessary to compensate for erosion of the contact surfaces due to electrical arcing and for wear of the fiber heel. As the heel wears, the points will open later

relative to the rotation of the crankshaft, thus retarding the timing slightly.

Points should be filed (if necessary) and cleaned before gapping.

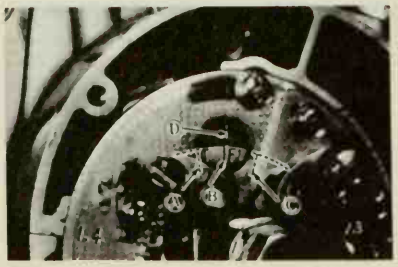
1. Remove the points cover.
2. Using the special nut, turn the engine over until one of the two sets of points is fully open.
3. With the proper feeler gauge blade, check the gap. The proper specification is 0.35 mm (0.018 in.), and the blade should be a slip fit between the points if the gap is correct.
4. If adjustment is necessary, loosen the screw which secures the point set to its plate,

Point gap (A) is adjusted after loosening the screw (arrow)

and use a small screwdriver at the pry point provided to adjust the gap.

CAUTION: *Loosen the screw just enough to allow the points to be moved. If loosened too much, the points will snap shut instead of holding the gap.*

5. Tighten the screw and recheck the gap. It may change slightly when the screw is tightened.
6. Repeat the procedure with the remaining points set. Try to adjust both sets so that the feeler gauge blade has the same "feel" in both sets. This will help to ensure accurate timing.
7. If it is not possible to gap the points correctly, the fiber heel is evidently worn; the points should then be replaced.



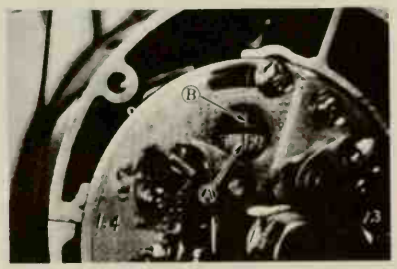
Lubrication

1. It is necessary to occasionally lubricate the cam follower fiber heel and the pivot point of the contact breakers. This minimizes wear and ensures that the timing will remain accurate for a longer period. A worn heel will retard the timing.
2. A small dab of grease (high melting point, if possible) should be applied to the lubricator wick so that the lubricator can distribute it onto the breaker cam. A drop of engine oil should be applied to the pivot points.
3. In both cases it is imperative that care be taken to keep the lubricant away from the points contact surface.
4. The lubricating wick should be adjusted so that it just contacts the breaker cam.
5. This lubrication should be carried out every 3,000 miles.

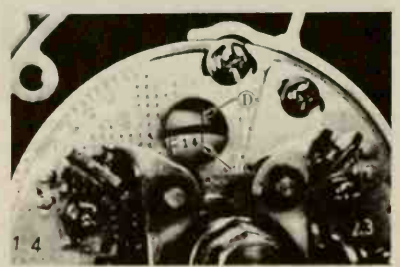
IGNITION TIMING

Transistorized Ignition

GS 850GT/GLT models are equipped with a solid-state ignition system which requires no maintenance or periodic inspection.

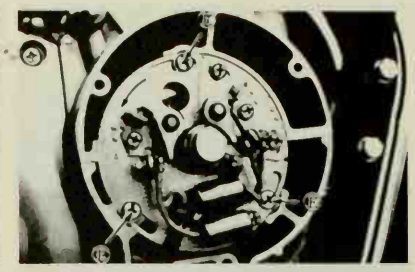


Timing marks: A, top dead center; B, fixed advance firing point; C, full advance firing point

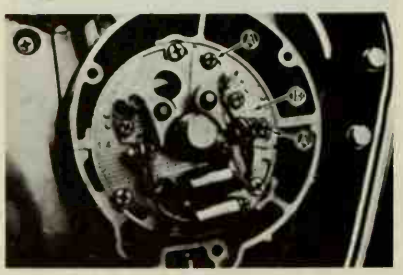


Breaker Point Ignition

DYNAMIC TIMING



1. Clean and gap both sets of points as described previously.
2. Hook up the strobe light according to the directions of the light's manufacturer to pick up the impulses from the No. 1 (left outside) cylinder.
3. Start the engine and adjust the idle, if necessary, to the recommended idle speed (1000 rpm).
4. Aim the light at the timing marks visible through the inspection hole in the points base plate. At idle, the "F" mark should align with the timing index mark.
5. To check ignition timing at full advance, increase the engine speed until the motor is turning 2,500–3,000 rpm. At this point, the timing index mark should be aligned with the full advance mark scribed into the timing advance mechanism.
6. If adjustment is necessary, carefully loosen the three base plate screws and rotate the plate so that the proper marks align at the specified rpm. Establishing this alignment at full advance is recommended. Tighten the base plate screws.
7. Repeat the procedure, this time having the strobe light pick up cylinder No. 2. If adjustment is necessary, loosen the two screws which secure points set 2.3 to its plate, and



The "F" mark should align with the timing mark (B) at idle

The full-advance firing mark (C) should align with the timing mark (D) above 2500 rpm

Timing for cylinders 1 & 4 is adjusted by loosening the three screws (E) and rotating the breaker plate

Timing for cylinders 2 & 3 is adjusted by loosening the two screws (A) and moving plate (B)

use a small screwdriver at the pry point provided to move the set so that proper mark alignment is achieved. Tighten the screws.

8. If it is not possible to acieve full advance alignment without moving the base plate or points set 2.3 all the way to the end of their range of allowable travel, it is possible that the points are either incorrectly gapped, or that they are worn to the point where they must be replaced.

STATIC TIMING

1. Connect one of the test light or tester leads to the primary wire terminal for the points set "1.4." Ground the other lead to the engine.
2. If the test device is not self-powered, turn the ignition switch *on* and be sure the kill switch is in the "on" position as well.
3. Turn the engine over in the normal direction of rotation until the "F" mark for cylinders 1 and 4 align with the timing index mark. The test instrument should react at the instant these marks align, indicating that the points have opened. If they do not, loosen the three base plate screws and rotate the base plate so that the points just open when these timing marks are in alignment. Moving the base plate clockwise will retard the timing, counterclockwise will advance it.

Cylinders 1 and 4 are now correctly timed. Tighten the base plate screws and recheck.

4. Repeat the procedure with points set 2.3. If adjustment is necessary, loosen the two screws which secure these points to their mounting plate and use a small screwdriver at the pry point provided. Tighten the screws and recheck the timing.

CARBURETORS

Carburetor adjustments to be made during a tune-up procedures include checking the float level, setting the idle mixture, idle speed, and carburetor synchronization.

All models except the GS 850GT/GLT use Mikuni VM26SS carburetors which are standard throttle-slide types. The GT/GLTs use BS32SS constant velocity (CV) units. Working procedures and specifications are therefore different.

Also, pilot screws on 1978 and later machines are pre-set and need no adjustment. This to meet clean air requirements.

Adjusting Float Level

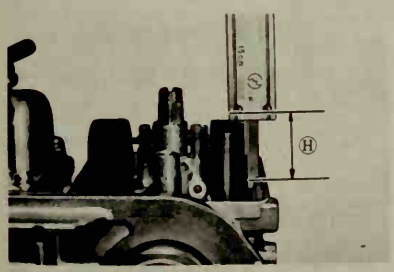
1. Float level is a measure of the amount of gasoline which will be in the float bowls during operation. While it is a critical specification, it will not normally need readjustment once properly set. Float level, therefore, need not be checked at every tune-up, but should be attended to from time to time.

2. A special gauge is available which allows the float level to be checked with the carburetors still on the motorcycle.

3. Remove the float bowl drain plug and install the gauge. Turn the petcock to the "Prime" position to refill the bowl, then turn it back to "On." Start the engine and allow it to idle at 1000–1100 rpm.

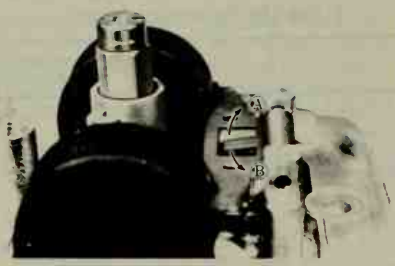
4. Hold the gauge line up against the carburetor body to check the float level. The level should be 2.5–3.5 mm (0.10–0.14 in.) on GS 750/E models, 3.0–4.0 mm (0.12–0.16 in.) on GS 750L and GS 850G/GL/GN, and 4.5–5.5 mm (0.18–0.22 in.) for the GS 850GT/GLT.

This is the distance between the fuel level in the gauge and the float bowl mating surface as shown in the illustration. If float level is not correct, proceed as follows.



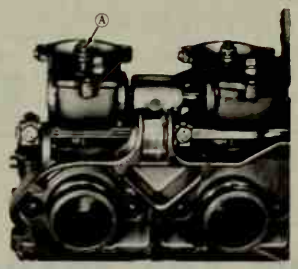
5. Remove the carburetors as a unit. Remove the float bowl and the float bowl gasket.

6. With a vernier caliper, measure the distance from the float bowl mating surface to the top of the float. Float heights are as follows:



GS 750/E	25–27 mm (0.98–1.1 in.)
GS 750L, GS 850G/GL/GN	23–25 mm (0.91–0.98 in.)
GS 850GT/GLT	21.4–23.4 mm (0.84–0.92 in.)

Checking float level (A)



Measuring float height (H)

Increase float height by bending the tang towards (B); decrease it by bending towards (A)

If float height is not within this range, push out the float pin to remove the float. Bend the float tang in the desired direction to raise or lower the float level. Bending the tang away from the carburetor body raises the fuel level; bending it towards the carburetor body lowers the fuel level.

Throttle slide locknut (A)

Idle Mixture and Idle Speed

1. These adjustments must be made with the engine at operating temperature.

2. Turn each pilot air screw in until it is lightly seated, then back them out 1¼ turns on 1977 models. On 1978 and later machines the pilot screw is preset and djustment is not necessary.

3. Adjust the idle speed to 1,000 rpm using the throttle stop screw.

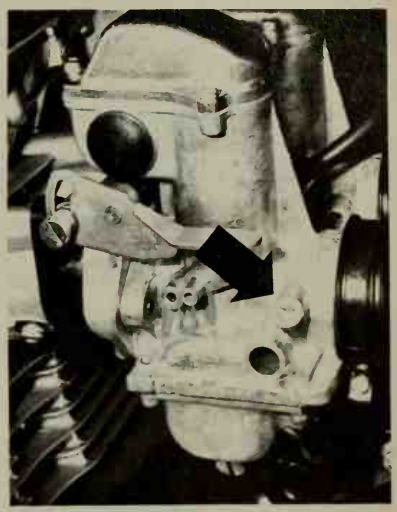
Synchronization (VM26SS)

1. A set of vacuum gauges are necessary to synchronize the carburetors.

2. Use longer fuel lines and raise the gas tank sufficiently so that the carburetor caps can be removed.

3. Remove the carburetor caps.

4. Install the vacuum gauges.

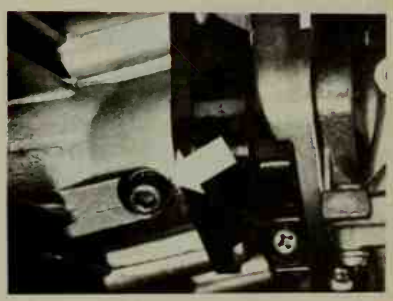


5. Start the engine and set it to run at about 1,500 rpm.

6. Note the vacuum gauge readings. Equalize the readings of all four carburetors by loosening the throttle slide locknuts and turning the adjusting screws to raise or lower the slides.

7. Readjust the idle speed to 1,000 rpm and adjust the throttle cables.

Synchronization (BS32SS)



Synchronization of the BS32SS units found on the GS 850GT/GLT is basically the same as outlined above for the VM26SS carbs. The throttle valve adjusters, however, are between the carburetors rather than beneath the carb tops. Delete Step 3.

Carburetor synchronizing screws (GT/GLT)

There are three valve adjusting screws (see illustration). Loosen the locknut before attempting adjustment. The screws ("B," "A," and "C" in the illustration) adjust carburetors 1, 2, and 4 respectively.

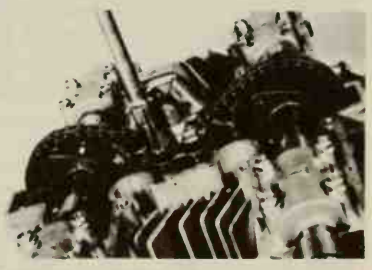
ENGINE AND TRANSMISSION

NOTE: *For engine component inspection techniques and procedures, refer to "Engine Rebuilding" in the General Information section.*

ENGINE REMOVAL AND INSTALLATION



GS 750

1. Drain the oil.
2. Remove the gas tank.
3. Disconnect the battery negative terminal.
4. Remove the left side cover. Disconnect the alternator leads, the starter solenoid negative terminal, and the points wires.
5. Disconnect the spark plug wires from the plugs.
6. Remove the air cleaner box. Remove the carburetors.
7. Disconnect the tachometer cable from the cylinder head.
8. Remove the exhaust header pipes.

Exhaust header pipes have their locations marked

9. Remove the left-side rider's footpeg.
10. Remove the clutch adjuster cover. Remove the screws which secure the sprocket cover and take off the cover.
11. Remove the engine sprocket.
12. Remove the right-side rider's footpeg. Remove the rear brake lever.
13. Remove the engine mounting bolts. Take the engine out from the right side of the frame.
14. Installation is the reverse of removal. Tighten the long bolts to 29 ft lbs and the short bolts to 14.5 ft lbs.
15. Be sure all hoses and wires are correctly routed and clamped where applicable.

Unbolting the cam chain idler

16. When installing the exhaust header pipes, note that their proper positions are indicated by a stamped letter near the end of each pipe. "L" is for the No. 1 cylinder, "C" for cylinders Nos. 2 and 3, and "R" for No. 4.
17. After installation, check the oil level, drive chain tension, and throttle cable adjustments before starting the engine.

GS 850

1. Drain the oil from the crankcase.
2. Remove the gear shift lever and the secondary drive box cover. Remove the drive box drain plug.
3. With the fuel petcock lever turned to "On" or "Res," disconnect the lines from the petcock. Disconnect the fuel sensor wire at the lower left side of the gas tank. Remove the tank securing bolt and take off the gas tank.
4. Disconnect the intake pipe from the breather cover.
5. Remove the side covers. Disconnect the battery leads. Disconnect the alternator wires, starter relay negative terminal, breaker point or ignition unit wires, neutral switch, gear position, oil pressure gauge wires and spark plug leads.
6. Remove the air cleaner box.
7. Remove the carburetors.
8. Loosen the drive shaft boot clamp and move the boot towards the rear. Remove the four bolts securing the universal joint and the drive shaft.
9. Remove the brake pedal and the right side footpeg.
10. Remove the exhaust system.
11. Remove the horn.
12. Disconnect the clutch and tachometer cables.
13. Remove the engine breather cover.
14. Support the engine with a jack and remove the engine mounting bolts and nuts. Remove the engine from the right side of the frame.
15. Installation is the reverse of removal. Note the following points.
16. Tighten 10 mm mounting bolts to 26 ft. lbs., and 8 mm bolts to 18 ft. lbs.

17. Use thread locking compound on the drive shaft bolts, and tighten them to 18–22 ft. lbs.

18. Secure exhaust pipe bolts to 7–10 ft. lbs., and muffler bolts to 13–20 ft. lbs.

19. Check all levels and cable adjustments before starting the engine.

TOP END

Cylinder Head Removal

1. It is possible to remove the cylinder head with the engine still in the frame provided that the gas tank, exhaust header pipes, air cleaner box, carburetors, and related cables and wires are removed or disconnected.

2. Remove the cylinder head cover.

3. Remove the cam chain adjuster by first loosening the adjuster screw locknut, tightening the adjuster screw, then removing the three cam chain adjuster mounting bolts.

4. Unbolt and remove the cam chain idler between the cam sprockets (four bolts).

Removing the tach drive stopper

Clamp the cam securely before removing the bearing caps

5. Remove the tachometer drive gear stopper screw, the stopper itself, and pull out the drive gear.

6. Clamp one of the camshafts securely in place using a vise-grip pliers or the like. Be sure to keep the jaws of the pliers clear of the cam lobes.

7. Remove the four bolts which secure each of the two cam bearing caps. These bolts should be loosened gradually and in a cross pattern.

8. Remove the vise-grip pliers. Remove the cam bearing caps. Remove the camshaft. Repeat the procedure with the remaining camshaft. Loop a length of wire around the cam chain and secure it to keep the chain from falling down into the crankcase.

9. To remove the cylinder head, first remove the adjustment shims from each valve. Mark them so that they can be reinstalled in their original locations. Valve adjustment must be checked upon assembly at any rate. Remove the two 6 mm set bolts, one at each side. Then remove the twelve 8 mm nuts. These nuts must be loosened gradually and in a cross-pattern beginning with the centermost nuts. After all the nuts have been removed, lift off the cylinder head, striking it carefully at the sides with a plastic mallet if it is struck.

10. Remove the tappet from each valve. Mark their locations.

Cylinder and Piston Removal

1. Remove the cylinder head as outlined above.

2. Grasp the cylinder block and move it straight up until it is clear of the studs. If the block is stuck, strike it carefully at the sides with a plastic mallet, but watch that no damage is done to the fins.

3. Mark the location of each piston before removal using a felt-tip marker or suitable substitute. Remove the piston wrist pin circlips and disgard them, new ones being required on assembly.

CAUTION: *Do not allow the circlips to fall into the crankcase. To avoid having to split the cases to retrieve a clip, cover the crankcase openings with a cloth.*

4. Press out the wrist pins with the special tool. Alternately, the pins can be removed by gently heating the piston crown and pushing the pin out with a suitable drift. Be sure to support the piston with one hand while doing this. Push the pin out with steady pressure. Never strike the pin in an attempt to remove it. This risks bending the connecting rod.

5. Remove the cylinder base gasket.

Inspection

CAMSHAFTS

1. Check the dam lobes for scoring or other imperfections. The lobes must be perfectly smooth. Replace the cam(s) if any damage is visible.

2. Use a micrometer to measure the height of each cam lobe and compare the readings against the following specifications:

750

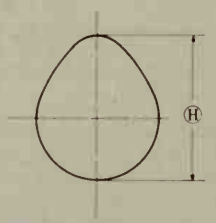
Valve	*Standard*	*Serviceable Limit*
Intake	36.265–36.295 mm/ 1.4278–1.4289 in.	36.15 mm/ 1.4232 in.
Exhaust	35.735–35.765 mm/ 1.4069–1.4081 in.	35.60 mm/ 1.4016 in.

850

Valve	*Standard*	*Serviceable Limit*
Intake	36.320–36.360 mm/ 1.4299–1.4315 in.	36.02 mm/ 1.4181 in.
Exhaust	35.770–35.810 mm/ 1.4083–1.4098 in.	35.47 mm/ 1.3965 in.

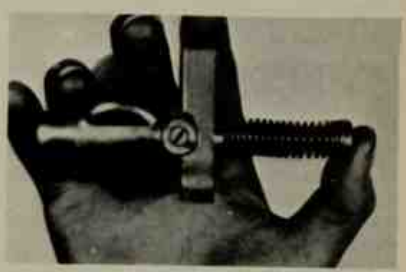
3. Inspect the cam journal bearings for scratches or imperfections.

4. Bearing clearance is most easily checked with Plastigage®. Be sure that the cam bearing caps are properly installed (align the arrows on the caps and head) and are torqued to 7.0 ft lbs. Standard bearing clearance is 0.020–0.054 mm (0.0008–0.0021 in.) and the serviceable limit is 0.15 mm (0.0059 in.).



5. Check the run-out of each camshaft by mounting each one in a set of v-blocks and measuring the run-out in the center with a dial indicator. Standard run-out is 0.03 mm (0.0012 in.), while the serviceable limit is 0.1 mm (0.0039 in.).

CAM CHAIN TENSIONER

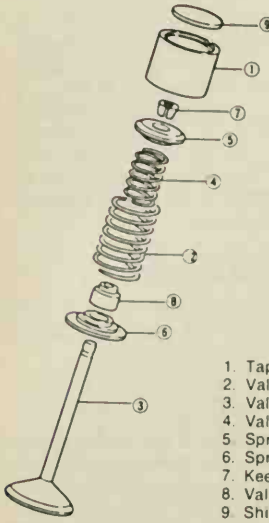


1. Check that the pushrod is free to move in and out. If it sticks or binds, replace the tensioner.

CYLINDER HEAD

1. Clean any traces of head gasket material from the cylinder head mating surface. Place a straight edge across the mating surface and check for warpage by attempting to slip feeler gauge blades between the head and straight edge. Standard head warpage is about 0.03 mm (0.0012 in.) while the serviceable limit is 0.25 mm (0.0098 in.). If the head is warped beyond this point, flatness should be restored by having the head milled.

Cam lobe height (H)

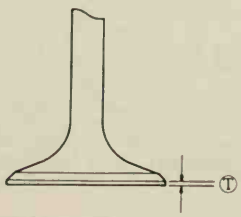


Checking the cam chain tensioner pushrod for free movement

2. Use a wire brush fitting on a power drill to decarbonize the combustion chambers. The valves should be left in place as this is done, as it minimizes the chance of causing damage to the valve seats.

VALVE ASSEMBLY

Before removing the valves, check their sealing ability by pouring a small quantity of gasoline into each port and allowing the head to sit for about five minutes. If the valves are properly seating, leakage into the combustion chamber will be minimal.



1. To remove the valves, and install them properly, a suitable C-clamp is necessary. Compress the valve springs and remove the split collars, retainers, springs, seals, and spring seats. Inspect the valves, guides,

Valve assembly

springs, and valve seats in the following manner. Keep each assembly separate so that every piece can be installed in its original location. New valve seals must always be used on assembly.

2. If considerable mileage has been covered, the valve springs should be replaced as a matter of course. Always replace valve springs as a set.

Valve face thickness (T)

Measure the free-length of each valve spring and compare the reading to the following specifications.

Inner springs have a standard free-length of 35.3–37.0 mm (1.39–1.46 in.) and a serviceable limit of 33.8 mm (1.33 in.)

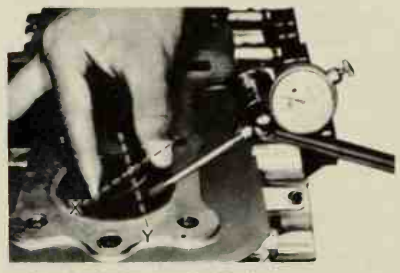
Outer springs have a standard free-length of 43.0–43.3 mm (1.69–1.70 in.) and a serviceable limit of 41.5 mm (1.63 in.).

Replace the springs if any is compressed more than the serviceable limit.

3. Each valve must be free to move up and down in its guide with little resistance. Any sticking or binding as the valve is moved in the guide will indicate that the valve stem or guide is in poor condition.

4. Inspect the valve, paying close attention to the edges of the valve head for pitting, burnt or broken edges, excessive carbon build-up, etc. A certain amount of carbon and lead deposits on the valve face and the top of the exhaust valve are inevitable. Heavy deposits should be carefully scraped off with a dull knife, or a wire wheel, and the valve finished up with very fine emery cloth.

Do not touch the valve seating area during these operations.



If the valve has burnt or broken edges, it must be replaced.

5. Check the thickness of the valve face as shown in the accompanying illustration. Standard thickness is 0.8–1.2 mm (0.0315–0.0472 in.). The valve should be replaced if thickness is less than 0.5 mm (0.0197 in.).

6. Carbon deposits should not extend too far up along the valve stem. This would indicate a worn or cracked valve guide.

7. Wet, oily deposits on the back of the valve head is indicative of a worn guide or bad seal. Less severe wear to these components show up as brown oil stains on the valve stem.

8. Holding a valve in your fingers, spin it while observing the head. A wobble is indicative of a bent valve. If a dial gauge is available, check the run-out of the head. Replace the valve if run-out exceeds 0.05 mm (0.002 in.). Run-out is the total indicated dial gauge reading.

Checking valve-to-guide clearance

Attempt to rotate the valve by hand when it is fully inserted into the guide. If the valve will not rotate easily, or if it sticks as it is turned, it is probably bent.

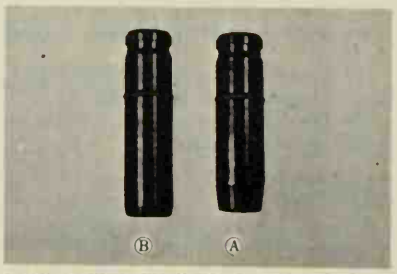
9. Check the valve-to-guide clearance. To do this, insert each valve into its guide, hold it about ½ in. off its seat, and check allowable movement in two directions with the aid of a dial indicator.

For the intake valves, standard clearance is 0.02–0.05 mm (0.0008–0.0019 in.) and the serviceable limit is 0.09 mm (0.0035 in.).

For the exhaust valves, standard clearance is 0.03–0.06 mm (0.0012–0.0024 in.) and the serviceable limit is 0.10 mm (0.0039 in.).

If the clearance exceeds the serviceable limit, the valve stems should be checked for wear (Step 10). If they are within the serviceable limits. The valve guides must be replaced.

10. Measure the diameter of the valve stem at three places along its length.



For intake valves, the standard diameter is 6.965–6.980 mm (0.2742–0.2748 in.). The valve must be replaced if the measured diameter is less than 6.90 mm (0.2716 in.).

For the exhaust valves, the standard diameter is 6.955–6.970 mm (0.2738–0.2744 in.). The valve must be replaced if the measured diameter is less than 6.805 mm (0.2679 in.).

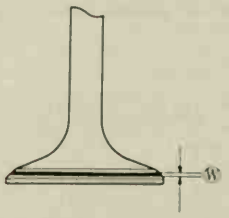
A quick check of the operational worthiness of a valve and guide can be accomplished by dipping the valve stem in oil and inserting it into its guide. Place a finger over the other end of the guide. Pull the valve a little way out of the guide and release it. The valve should be drawn back into the guide by suction if the components are in serviceable condition.

11. Guides can be removed with a suitable drift. Heating the head in an oven beforehand will facilitate removal. After a guide is removed, the guide hole should be reamed with a 12.2 mm reamer.

12. Valve guides should be installed with the head at room temperature. Oiling the guide hole and guide will facilitate installation. Be certain that the guide is fully seated.

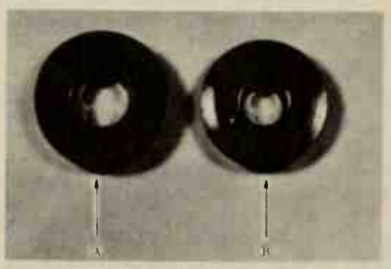
Intake guides (A) and exhaust guides (B) are not interchangeable

Reaming a valve guide



NOTE: *Exhaust and intake guides are different. The intake guides have a more pronounced bevel at the lower end.*

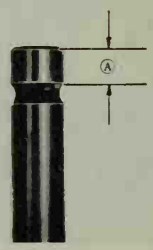
13. After installation, the guide should be reamed with a 7 mm reamer. Clean the inside of the guide thoroughly after this operation.



14. After installing a new guide, the valve seat should be recut and the valve lapped in.

15. Valve seat width should be checked with red lead. Coat the valve seating area on the head with the red lead, than install the valve, rotating it back and forth. Inspect the seating area on the valve. The seating area should be 1.0–1.2 mm (0.04–0.05 in.) all the way around the valve. If the seating area is greater than 1.5 mm (0.06 in.), or is uneven, the valve seat in the head must be recut. Refer to "Valve Seat Service," below.

16. Installation of the valve assembly is the reverse of removal. Note than the upper and



Valve seat width (W)

Upper (A) and lower (B) valve spring seats are different

Springs are installed with the close coils (arrows) towards the head

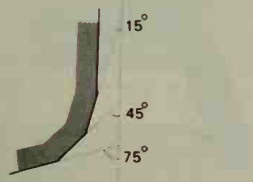
Do not reduce dimension (A) to less than 4.0 mm (0.16 in.)

lower spring seats are different, the lower spring seat having a larger hole. Coat the length of each valve stem, and the lips of the valve seals, with molybdenum disulfide lubricant before installation.

17. Note that the valve springs are progressively wound. They must be installed so that the close coils are towards the head.

VALVE SEAT SERVICE

1. Valves should be lapped into their seats if the leakage test shows poor sealing, if the valve edges or seat in the head are pitted, if the motorcycle has covered considerable mileage, or if new valves or guides are fitted.



2. Clean off all carbon build-up on the surface of the combustion chamber. Place three small dabs of valve lapping paste around the circumference of the valve head and place the valve into the guide.

3. If you have a lapping tool, use it as the manufacturer directs. Usually the tool will turn the valve back and forth while rotating it around the seat at the same time. Do not use excessive pressure during the operation.

If you do not have such a tool, a piece of thick fuel line placed over the valve stem works just as well. Turn the valve back and forth and rotate it to a new position every few seconds.

NOTE: *Check the condition of the valve face and seat frequently. When a smooth, even finish is evident, stop lapping. Excessive lapping may lead to a pocketed valve.*

4. Remove the valve and clean it thoroughly. Remove any traces of lapping compound from the seat and the combustion chamber. Swab out the guide with a cotton swab soaked in solvent. Squirt a little oil into the guide so that it may carry away any particles inside.

Valve seat dimensions

5. Check the width and condition of the valve seat. The seat should be about 1.0–1.2 mm (0.04–0.05 in.) wide, all the way around. If seat width is too narrow or too large, or if width varies, or if pitting still remains, the seat must be recut and the valve replaced.

6. Three cuts are necessary to restore a valve seat to a serviceable condition. First, make cuts at 15° and 75°, removing as little material as possible. Next, use a 45° cutter to produce a valve seat width of 1.0–1.2 mm (0.04–0.05 in.). This cut must be done very carefully; if too much material is removed, the valve may move so close to the camshaft that proper adjustment is made impossible.

7. After recutting the valve seat, lap the valve into place as outlined above.

8. If cutting the valve seat had raised the valve so much that valve adjustment is not possible, it is permissible to grind some material from the end of the valve stem to reduce its length. The distance from the valve keeper groove to the tip of the valve must not be reduced to less than 4.0 mm (0.16 in.), however, or the valve must then be replaced. When installing a valve whose tip has been ground, be sure that the tip still protrudes above the valve keepers.

9. Valves must be adjusted on assembly if lapping or cutting procedures have been carried out

CYLINDERS AND PISTONS

1. Make a visual inspection of the cylinder bore, noting any imperfections. The cylinder walls should be uniformly smooth.

2. With an inside micrometer, measure the diameter of each bore at the top, middle, and bottom. Make measurements in two directions, 90° apart, both parallel and perpendicular to the piston wrist pins.

On 750s with a standard bore, no measurement should exceed 65.100 mm (2.5629 in.).

On 850s with standard bores, no measurement should exceed 69.080 mm (2.7197 in.).

Maximum allowable difference between cylinders is 0.1 mm (0.004 in.).

Standard cylinder inside diameter is as follows:

750	65.000–65.015 mm/2.5591–2.5596 in.
850	69.000–69.015 mm/2.7165–1.7171 in.

If any bore measurement exceeds the service limits above, the cylinders should be bored out to the first oversize. Oversized pistons are 0.5 and 1.0 mm above standard.

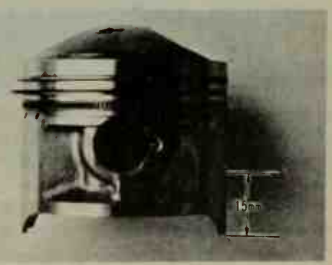
NOTE: *When boring cylinders, allow adequate time between cuts for the block to cool. This will eliminate the danger of warpage. Bore cylinders in order 2, 4, 1, 3.*

3. Make a visual inspection of the pistons. Scoring, scuffing, or seizure marks on the piston skirts may be removed with a fine grade of emery or crocus cloth if they are not too severe. Sanding should be done in a cross-hatch pattern. If the damage is severe (more than about ½ in. wide), the pistons should be replaced.

4. The rings must be free to move in the piston grooves. If they cannot, either they are carbon-clogged (which necessitates replacing the rings and cleaning out the grooves), or metal has been pushed into the grooves by a piston seizure. In this event, pistons and rings must be replaced. Carbon-clogged rings are almost always broken when an attempt is made to remove or free them, so be prepared to buy a new set.

5. Measure the diameter of the pistons perpendicular to the wrist pins at a point 15 mm (0.6 in.) above the edge of the skirt. Piston diameters for standard pistons are:

750	64.80 mm (2.5512 in.)
850	68.880 mm (2.7118 in.)



If the pistons measure less than this, they should be replaced. If wear of this kind has occurred, the cylinders are probably worn as well, and the solution is to have them bored out to the next oversize.

Standard piston diameters are 64.945–64.960 mm (2.5569–2.5575 in.) for the 750 and 68.945–68.960 mm (2.7144–2.7150 in.) for the 850.

Note: *If oversized pistons are needed due to a worn bore or damaged piston, obtain the replacement pistons first, then have your dealer or a machine shop bore the cylinders to the proper size. This is obtained by measuring the diameter of the new pistons and boring the cylinders to that size plus the piston-to-cylinder clearance of 0.050–0.060 mm (0.0020–0.0024 in.).*

Oversized pistons are available in 0.5 mm and 1.0 mm sizes.

6. Check the condition of the piston wrist pins and replace them if step-wear or discoloration is evident. The wrist pins should be a snug fit in the piston holes. If they are too

Measure piston diameter 15 mm above the edge of the skirt

loose, the pistons and pins should be replaced.

Check the diameter of the wrist pins at three places along their length. Standard wrist pin diameter is 15.995–16.000 mm (0.6297–0.6299 in.). Replace the pin if any reading is less than 15.96 mm (0.6283 in.).

Check the diameter of the wrist pin bores in the pistons. Standard size is 16.002–16.008 mm (0.6300–0.6302 in.). Replace the pistons

if the bore is larger than 16.08 mm (0.6331 in.).

Check the diameter of the small end bores. Standard bore size is 16.006–16.014 mm (0.6302–0.6305 in.). The rod must be replaced if the bore exceeds 16.05 mm (0.6319 in.).

Standard piston-to-wrist pin clearance is 0.002–0.013 mm (0.0001–0.0005 in.). The service limit is 0.12 mm (0.0047 in.).

Standard rod-to-wrist pin clearance is 0.006–0.019 mm (0.0002–0.0007 in.). The service limit 0.080 mm (0.0031 in.).

7. Although not as conclusive as a direct measurement, the condition of the wrist pins and small ends can be checked by inserting the pins and checking for vertical movement. There should be none. If there is noticeable movement in the pins, either the pins or the rods, or both, are in need of replacement. If the rod small ends are discolored or scored, the rods should be replaced.

8. Check the connecting rods for a bent condition. This can be accomplished with two small rectangular blocks of metal of equal thickness. Insert the wrist pins into the rods, and position the pieces of metal beneath them on either side of the rods and resting on the crankcase. Rotate the engine so that the wrist pin rests on the blocks. Both sides of the wrist pin must contact the metal blocks, or the rod is bent and must be replaced.

9. Before installation, decarbonize the piston crowns. Remove any carbon from the ring grooves with a piece of broken ring or a very thin screwdriver. Be careful not to scratch the grooves.

Carefully check the cylinder, cleaning the bores thoroughly. If considerable mileage has been covered, honing the cylinders and fitting new rings is recommended. If the cylinders are honed, make a strenuous effort to clean them thoroughly afterwards, preferably with very hot soapy water and a stiff brush. This is to remove any abrasive particles deposited by the hone in the course of the operation.

Remove any traces of gasket material from the cylinder base and the head mating surface.

10. Be sure that all oil passages in the cylinder are clear.

11. Replace the cylinder base o-rings. Check that any o-rings and the important dowel pins fitted to the cylinders are in their proper locations before installation.

PISTON RINGS

Piston rings should be checked for side clearance, thickness, end-gap (installed) and free end-gap. These checks should be made on both new and used rings.

1. Piston ring side clearance is checked with the rings installed on the piston. Insert a feeler gauge blade between the ring and the ring groove and check that the clearance is within the proper specification. They are as follows:

a. For the top ring, standard clearance is 0.020–0.055 mm (0.0008–0.0022 in.) and the serviceable limit is 0.18 mm (0.007 in.).

b. For the second ring, standard clearance is 0.020–0.060 mm (0.0008–0.0024 in.) and the serviceable limit is 0.15 mm (0.0059 in.).

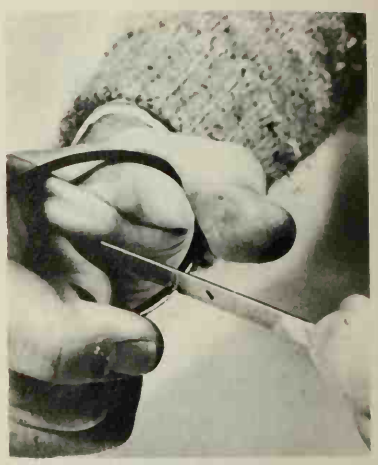
c. For the oil ring, the serviceable limit is 0.15 mm (0.006 in.).

If the clearance is too large, the rings or grooves are worn. If too small, metal may have been pushed into the grooves due to a piston seizure. Check that the grooves are not just carboned up. If new rings do not bring the clearance to the proper value, the pistons must be replaced.

Measuring piston ring end-gap

2. To remove the rings from the piston, use a ring spreader. They are available at most auto stores. Decarbonize the ring grooves.

3. Measure the thickness of the two compression rings. Standard thickness for the top ring is 1.175–1.190 mm (0.0463–0.0469 in.), and for the second compression ring 1.170–1.190 mm (0.0460–0.0469 in.). Serviceable limit for both compression rings is 1.10 mm (0.043 in.).



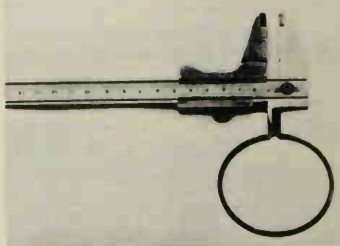
4. If possible, check the width of the piston ring grooves. For the compression rings, groove width (standard) is 1.21–1.23 mm (0.0476–0.0484 in.), while the serviceable limit is 1.30 mm (0.051 in.). For the oil ring, standard groove width is 2.51–2.53 mm (0.0988–0.0996 in.), while the serviceable limit is 2.60 mm (0.102 in.).

If the groove width is greater than the serviceable limit, the piston must be replaced.

5. To check the ring end-gap, ensure first that the cylinder bore is not excessively worn. Place each compression ring, in turn, into the bottom of its cylinder and push it in an inch or more using the piston skirt to align the ring in the bore. Measure the end-gap with a feeler gauge. If the end-gap is larger than the service limit, the rings must be replaced. If the measured end-gap of new rings is too large, the cylinder is worn and should be bored to the next oversize.

Standard end-gap for both compression rings is 0.1–0.3 mm (0.004–0.012 in.). Rings must be replaced if end-gap exceeds 0.6 mm (0.024 in.) for the 750s and 0.7 mm (0.028 in.) for the 850s.

If new rings are fitted and the end-gap is too small, the ring ends must be filed. Hold the ring stady as illustrated, closing the ends over a thin, fine file. Do not squeeze the ring, as this is the easiest way to break it. A few strokes of the file will increase the end-gap.

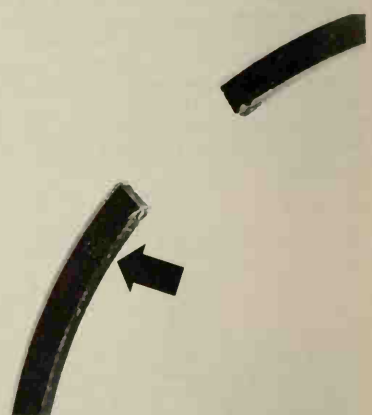


Filing ring ends

CAUTION: *Do not make more than a few strokes before checking the end-gap again. It is easy to remove too much metal.*

Do not allow the file to slip out of the ring as this risks breaking it.

6. Check the free end-gap of the compression rings with a vernier caliper. On the 750, standard free end-gap is 8 mm (0.31 in.) while the serviceable limit is 6 mm (0.24 in.) for both rings.



On the 850, standard free end-gap for the top ring is 9 mm (0.35 in.) and the serviceable limit is 7.2 mm (0.28 in.). For the lower compression ring the values are 9.5 mm (0.37 in.) and 7.6 mm (0.30 in.).

Measuring free end-gap

CAM CHAIN TENSIONER

1. Check that the cam chain tensioner pushrod can move in and out smoothly. If it sticks or binds, remove it by first removing the lock screw. Lubricate the pushrod with molybdenum disulfide lubricant and the pushrod guide with motor oil. If lubrication does not ease the movement, the assembly must be replaced.

Always install rings so that the letter near the end-gap faces up

2. If the unit has been disassembled, position the lock shaft and holder as illustrated before assembly. Oil the lock shaft first. Tighten the shaft assembly to 22.3–25.3 ft lbs.

3. The handle is fitted to the holder by means of a left-hand thread. Turn the handle

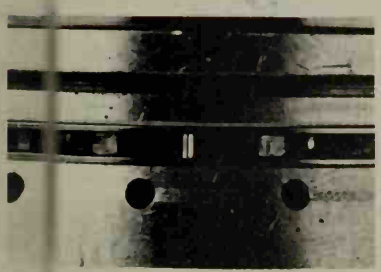
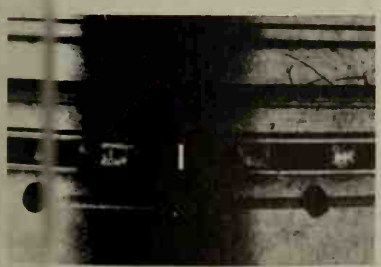
Cyli der and Piston Inst ation

1. hen installing the piston rings, note that t compression rings are installed with the m ufacturer's mark (the small letter near the e gap) facing *up*. All rings must have the s e mark.



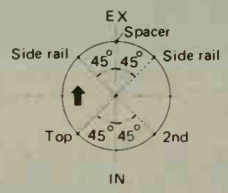
NO : *The compression rings are not interc ngeable. The upper compression ring is rome-plated. The lower one has a we -shaped cross-section. Refer to the illu ation.*

2. install the three-piece oil ring, install one on the piston below the oil ring groov fit the expander, then move the rail into p e. Install the top rail.

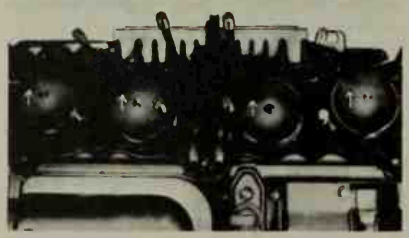


If "-marked rings are being used, be sure that t oil ring expander ends do not overlap.

Uppe A) and lower (B) compression ring profiles



Oil ri expander ends should not overlap



3. Use a ring-expander when installing the compression rings to reduce the chance of breaking them.

4. Ring end-gaps must be staggered around the piston so that they do not overlap. Compression ring end-gaps should be positioned at 45° on either side of the piston centerline on the intake side. The oil ring expander end-gap

Ring end-gap positions

Fit the pistons with the arrows pointing towards the exhaust ports

should be positioned directly at the front of the piston with the rail end-gaps at 45° on either side of it. Refer to the accompanying illustration.

5. Install the pistons on their connecting rods so that the arrow stamped onto the piston crown points towards the exhaust (front) of the engine.

NOTE: *Be sure to use new wrist pin circlips.*

6. Oil the connecting rod small ends. Slip the wrist pins into place, heating the piston crown as on removal if necessary. Install the wrist pin circlips with a needle-nosed pliers. Be sure that each circlip is firmly seated in its groove and arranged so that the circlip end-gap and the cut-out in the piston do *not* align.

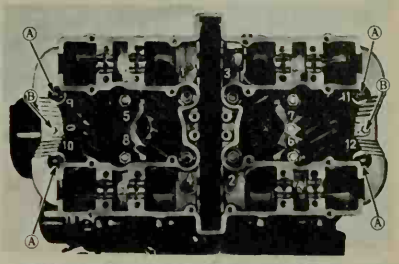
7. Lubricate the rings and piston skirts with clean motor oil.

8. Install the cylinder base gasket.

9. Compress the piston rings and install the cylinders.

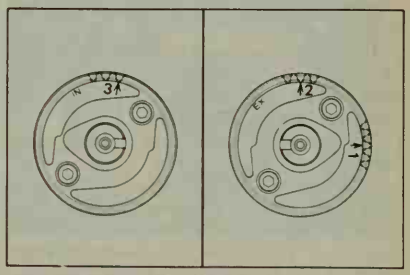
Cylinder Head Installation

1. Fit the cylinder head gasket.



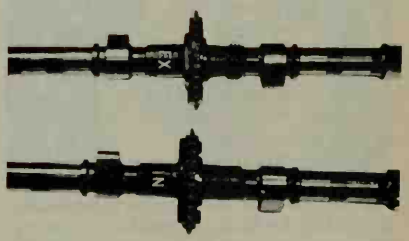
2. Install the cylinder head. Run the head nuts down until they are just hand-tight. Note that the four crown nuts and copper washers are installed on the outermost studs.

3. Refer to the illustration for cylinder head nut tightening order. Nuts should be tightened gradually and in a cross-pattern until the proper torque of 25.3–29.0 ft lbs is reached.



4. Install the two 6-mm set bolts and tighten them to 5.1–8.0 ft lbs.

5. Oil and install the valve tappets and shims.



6. If the camshaft sprockets were removed, install each sprocket onto the proper cam, referring to the accompanying illustrations. Tighten the sprocket bolts to 7.2 ft lbs.

7. Lubricate the cylinder head bearings with clean engine oil. Coat the journal areas of each camshaft with molybdenum disulfide lubricant.

8. Put each camshaft in place, noting that they are marked either "IN" or "EX." In addition, the left and right sides of each cam is marked to aid installation.

9. Engage the cam chain with the cam sprockets.

10. Remove the points cover. Slowly turn the engine over in the normal direction of rotation (clockwise a seen from the right side) until the "T" mark on the timing plate for cylinders 1 and 4 is aligned with the stationary timing mark.

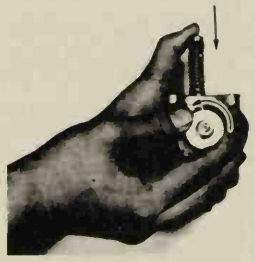
11. Take up the cam chain slack, disengaging the chain from the exhaust cam sprocket. Turn the exhaust cam so that the arrow mark on the sprocket (marked "1") is flush with the cylinder head cover mating surface. At this point, the other arrow (marked "2") will point towards the vertical. Pull up the cam chain and engage the chain with the exhaust cam sprocket in this position.

12. The exhaust cam arrow mark ("2") now points towards a cam chain pin. Starting with this pin, count off 20 pins. Turn the intake camshaft so that the arrow (marked "3") on the intake camshaft sprocket points towards this 20th pin. Refer to the illustration.

Valve timing is now set correctly.

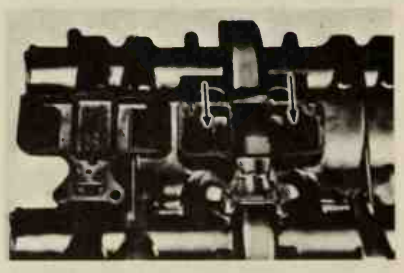
13. Secure both camshafts with vise-grips as on removal, and install the bearing caps. Note that the caps must be installed so that the arrow on the cap points in the same direction as the corresponding arrow embossed in the head.

14. Install the cam bearing cap bolts. Tighten the bolts gradually and evenly in a cross-pattern until the proper torque (2.9–4.3 ft lbs) is reached.



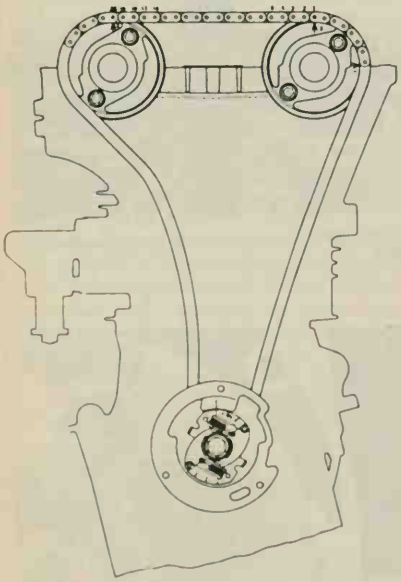
15. Install the tachometer drive gear.

16. Install the timing chain idler, torquing the bolts to 4.3–5.8 ft lbs.



17. To install the cam chain tensioner, turn the lock shaft handle counterclockwise while pushing the pushrod in as far as possible. Continue turning the handle until it refuses to turn further. Tighten the lockscrew to keep the pushrod in place. Bolt the adjuster assembly to the cylinder. Back out the lockscrew ¼ to ½ turn. Hold the lockscrew in place and tighten its locknut.

18. To check the operation on the cam chain tensioner, turn the lock shaft handle counterclockwise while turning the engine over opposite the normal direction of rotation. Release the handle and turn the engine slowly in the normal direction of rotation (clockwise as seen from the right side). The lock shaft handle should rotate by itself. If it does not, or if it rotates in a halting manner, remove and disassemble the tensioner as outlined in the tensioner service section preceeding.



19. Adjust the tappets.

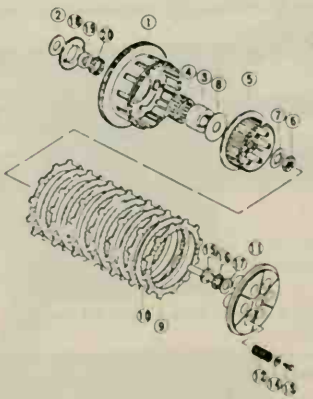
Oil separators

Valve timing marks

20. The remainder of the assembly procedure is the reverse of disassembly. Install the four oil separators in the cylinder head cover in the positions illustrated. Tighten the 16 cylinder head cover bolts gradually and in the order illustrated until a torque of 5.1–8.0 ft lbs is reached.

CRANKCASE COVER COMPONENTS



The following sections deal with the removal, inspection, and installation of those components found beneath the left and right crankcase covers. These include the clutch, oil pump, breaker points, alternator, starter drive, and shift mechanism. These components can be serviced with the engine in the frame.

Note the following points:

a. Always remove and install crankcase cover screws with an impact driver to prevent damage to the screw heads. Coat the threads of the screws with a bit of lubricant or anti-seize paste before installing to facilitate future removal.

b. New cover gaskets should always be used. Remove any traces of old gasket or gasket sealing compound from the covers and the crankcase mating surfaces.

c. During the disassembly procedure it may be necessary to keep the engine from turning over while a component is removed. There are several ways to do this. If

the engine is in the frame, place the transmission in gear and apply the rear brake. If the engine has been removed from the frame, loop a length of old drive chain around the countershaft sprocket and secure the end in a vise. Engage the transmission and the engine will not turn over.

Clutch (750)

REMOVAL

1. Drain the oil.
2. Loosen the pinch bolt and carefully pull the kickstarter lever off of its splined shaft.
3. Remove the clutch cover screws. Remove the clutch cover. If the cover is stuck, tap carefully at its sides with a plastic mallet to free it.
4. Remove the clutch cover gasket. A new one should be used on assembly.
5. Gradually, and in a cross pattern, loosen the six clutch spring bolts until they are free. Remove the bolts, washers, springs, and pressure plate. Remove the washer, bearing, and lifter.
6. Remove the clutch friction and steel plates, first making note of their order of installation.
7. Lock the clutch hub in place using either the special tool or by locking the transmission in place. Bend down the lock tab on the clutch hub nut. Loosen and remove the nut. Pull off the clutch hub.
8. Screw two 6-mm bolts into the primary driven gear spacer and pull the spacer out.
9. Remove the clutch housing and primary driven gear.

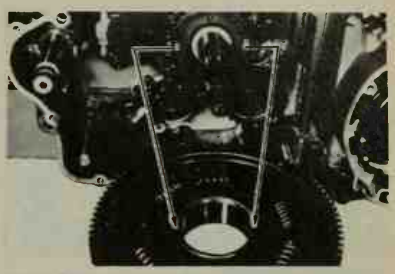
INSPECTION

1. Check the condition of the kickstarter shaft oil seal. If it leaks, or if the lips show signs of damage, pry out the old seal with a small screwdriver. Press the new seal straight into the cover. Apply some oil or grease to the seal lips before installation.
2. Check the condition of the clutch cover mating surface. Remove any burrs or imperfections with an oilstone.
3. Measure the thickness of each friction plate and replace the set if any plate is worn to less than 2.7 mm (0.11 in.). Thickness of new plates is 2.9–3.1 mm (0.114–0.122 in.).
4. Place the clutch plates on a flat surface, such as a piece of glass, and check for excessive warpage by attempting to slip a feeler gauge blade between the surface and the plate. Replace the steel and friction plates as a set if warpage exceeds 0.3 mm (0.12 in.).
5. Measure the free-length of each clutch spring and replace them as a set if any are found to be less than 39.0 mm (1.54 in.) long, or if their length varies. Free-length of new clutch springs is 40.4 mm (1.59 in.). Be sure that the spring bolts are tightened evenly on assembly.
6. Check the friction plate tabs for wear or damage. Check the clutch housing for indented wear caused by the tabs. Remove any burrs with a file or oilstone.
7. Check the corresponding splines of the clutch hub and steel plates for indented wear.
8. Check the condition of the housing bearing. Rollers must be in good condition, free of any obvious signs of damage, discoloration, etc. Replace the bearing if imperfections are noted.
9. Check the condition of the lifter bearing, looking for obvious signs of damage.
10. Check the pressure plate for cracks.
11. Inspect the primary driven gear teeth for wear or pitting.

ASSEMBLY

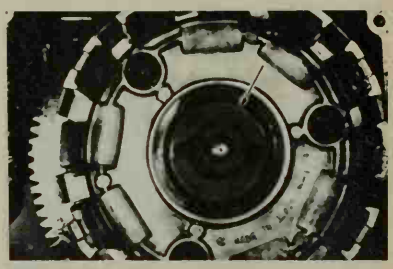
1. Assembly is basically the reverse of disassembly.
2. When fitting the clutch housing, note that the tabs on the oil pump drive gear must engage the cut-outs on the back of the housing.
3. Install the spacer, making sure it is fully seated.
4. Install the housing thrust washer, making sure that the washer is installed with the grooved side facing the clutch housing.
5. After fitting the clutch hub, install the hub and tighten it to 29.0–43.4 ft lbs. Bend down the lockwasher tab to secure the nut.
6. After installing the steel and friction plates, the lifter assembly, and the pressure plate, install and tighten the clutch spring bolts. Tighten the bolts gradually, and in a cross pattern until the desired torque of 2.9–4.3 ft lbs is reached.

Clutch (850)



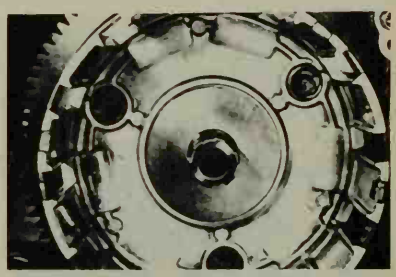
REMOVAL

1. Drain the oil.
2. Remove the kickstarter lever, if fitted.
3. Remove the right side footpeg.
4. Disconnect the clutch cable at the cover.
5. Remove the clutch cover screws. Remove the cover, tapping around it with a plastic mallet to break it free if it is stuck. You should have a drip pan beneath the cover to catch excess oil.
6. Gradually and evenly loosen and remove the six pressure plate spring bolts. Remove the pressure plate and springs.
7. Remove the clutch plates.
8. Lock the clutch hub in place using either the special tool or by locking the transmission in place. Bend down the locktab on the clutch hub nut. Remove the nut. Remove the clutch hub.
9. Screw two 6-mm bolts into the primary driven gear spacer and pull the spacer out. Remove the clutch housing and primary driven gear.
10. Disassemble the clutch hub, if desired, by squeezing the driven plate with a pliers and removing the piano wire clip.

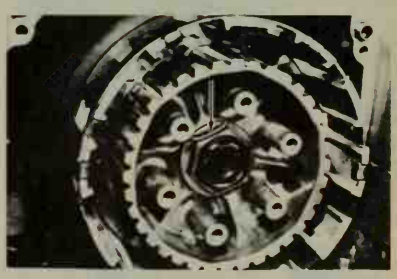


INSPECTION

Refer to "Inspection" for the 750 clutch given above. Procedures are the same. Specifications may differ. For the 850, they are as follows:



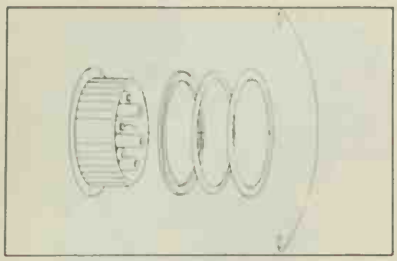
1. The thickness of new friction plates is 2.7–2.9 mm (0.11–0.12 in.). They should be replaced as a set if any measures less than 2.4 mm (0.094 in.).
2. Replace the plates as a set if any friction plate is warped more than 0.2 mm (0.008 in.) or any steel plate more than 0.1 mm (0.004 in.).
3. Standard clutch spring free-length is 40.4 mm (1.59 in.), and the serviceable limit is 38.8 mm (1.53 in.).
4. Friction plate tabs should be at least 11.0 mm (0.43 in.) wide.



When fitting the clutch housing, the oil pump drive gear tabs must engage the cut-outs on back of the housing

Spacer installed

Thrust washer installed



Clutch hub nut lockwasher

ASSEMBLY

1. When reinstalling the clutch housing, fit the projections on the oil pump drive gear into the clutch gear notches. Rotate the assembly to be sure of proper installation.
2. Install the spacer and be sure it is fully seated.
3. Be sure that the thrust washer is fitted so that the grooved side faces inwards.
4. Clutch hub assembly has spring seat, spring, and driven plate fitted to the hub in that order.

NOTE: *Use a new piano wire clip.*

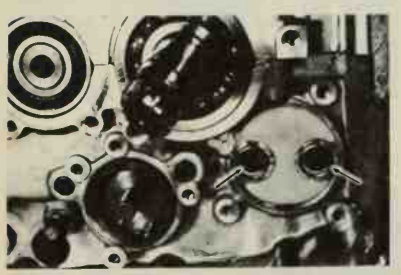
5. Clutch hub nut is tightened to 36–51 ft. lbs.
6. Clutch plates are installed with a friction plate first, then steel and friction plates alternately. Tighten spring bolts gradually and in a cross-pattern to 8–10 ft. lbs.

Clutch hub assembly

7. Use a new clutch cover gasket. When fitting the cover, be sure that the clutch lever rack and pinion is properly engaged.

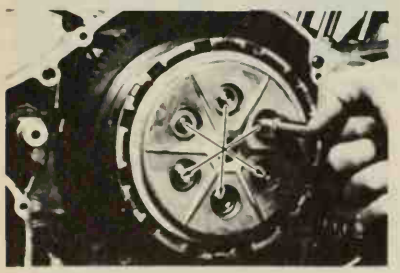
Oil Pump

REMOVAL



1. Drain the oil. Remove the clutch assembly as outlined above.
2. Remove the three screws and pull off the oil pump.

INSPECTION



Refer to "Lubrication System," for inspection procedures.

INSTALLATION

Installation is the reverse of removal. Be sure that the two o-rings are in place behind the oil pump. Use a non-permanent thread locking compound on the pump mounting screws.

Gearshift Mechanism

REMOVAL

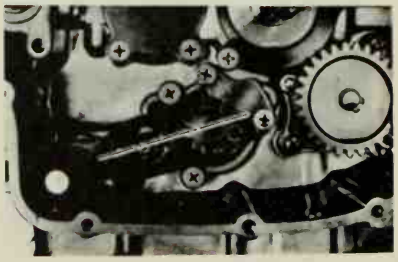
1. Drain the oil. Remove the clutch assembly as outlined above.
2. Loosen the pinch bolt and carefully pull the gearshift lever off its splined shaft.
3. Pull out the gear shift shaft.
4. Remove the cam guide and pawl lifter plate screws and take off those parts and the cam gear and pawls.

The narrow side of the gearshift pawl (A) is fitted as shown

INSPECTION

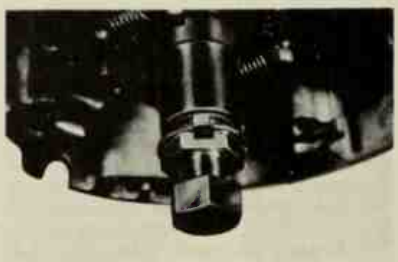
1. Check the gearshift return spring for damage.
2. Check the meshing gear teeth for condition.

INSTALLATION



1. Installation is the reverse of removal. Be sure that the gearshift return spring arms are fitted to either side of the arm stopper pin.
2. When fitting the gearshift pawls to the cam gear, note that the narrow side of the pawls are installed closest to the shift drum.
3. Mesh the shift gears as illustrated.
4. Secure the cam guide and pawl lifter screws with a non-permanent thread locking compound.

NOTE: *The four gearshift component screws are somewhat shorter than the other securing screws in the clutch housing. If other components, such as the oil pump or bearing retainers, are removed at the same time, be sure not to confuse the screws.*

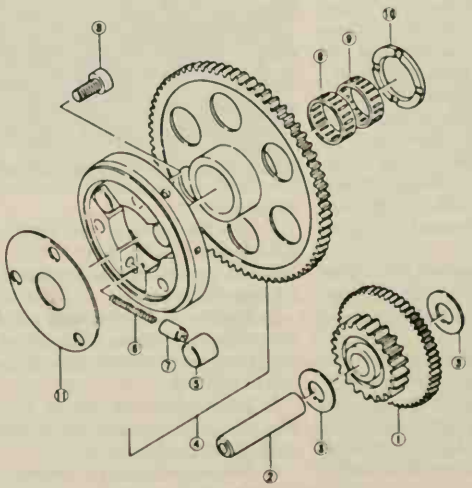


Breaker Point Assembly

REMOVAL

1. Remove the breaker points cover. Disconnect the two leads at the top of the air cleaner or at the primary terminals.
2. Scribe a mark on the breaker plate and housing to facilitate ignition timing. Remove the three securing screws and take off the breaker plate.
3. Remove the timing advance mechanism bolt. Slide off the timing advance mechanism.

Correct gearshift ratchet installation



Tighten the advance mechanism bolt to 13.0–20.3 ft lbs.

INSPECTION

1. The timing advance mechanism movement must be free. When the breaker cam is turned so that the weights move out to the fully extended position, releasing the cam should result in its returning to the original location. If it will not, try penetrating oil or the like to ease movement. Check for weak springs. Replace the unit if proper action cannot be obtained.

INSTALLATION

1. Installation is the reverse of removal. When installing the timing advance mechanism note that it is located by a pin.
2. Tighten the timing advance mechanism bolt to 13.0–20.3 ft lbs.
3. When installing the breaker plate, line up the scribed marks made before removal. If no marks were made, it is necessary to retime the ignition. Timing should be checked in any case.

Alternator/Starter Drive

REMOVAL

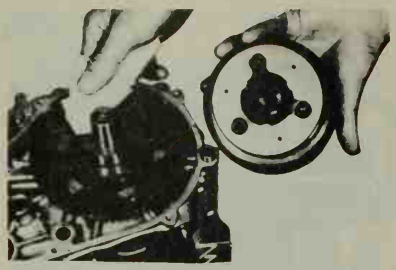
1. Remove the alternator cover.
2. Lock the crankshaft and remove the alternator rotor mounting bolt.
3. The rotor is a push-fit onto the tapered crankshaft. It can be removed using either a slide-hammer or a large gear puller.
4. Remove the starter clutch and the starter gear.
5. Remove the idler gear pin complete with the idler gears and washers.

INSPECTION

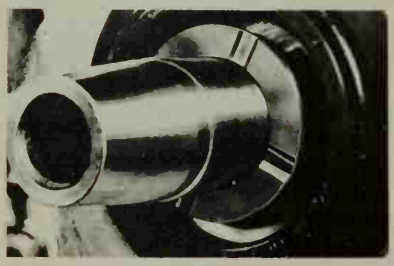
1. Refer to "Electrical System," for alternator tests.
2. Check the condition of the starter drive gears and replace them if the teeth are worn or broken.
3. The starter clutch should be replaced if defective, a condition indicated if the starter motor, but not the engine, turns over when the starter button is pushed.
4. Check the condition of the starter gear needle bearings. The bearings should be replaced when the rollers show any signs of damage such as flat spots, pitting, or discoloration.

INSTALLATION

1. The thrust washer behind the starter gear must be installed correctly. The washer's hole has a bevel on one side, the other side being plain. The washer must be installed so that the bevelled side faces the crankshaft bearing.
2. Note that a washer is installed on either side of the idler gear.
3. Clean the crankshaft taper thoroughly with a solvent before installing the components. Tighten the rotor bolt to 43.4–50.6 ft lbs. on 750s or 65–73 ft. lbs. on the 850s. non-permanent thread locking compound is recommended.



A thrust washer is installed on either side of the idler gear



LOWER END

Disassembly

1. Remove the engine from the frame.
2. Remove the cylinder head and cylinder and piston assembly. Refer to "Top End," above.
3. Refer to the "Crankcase Cover Components" procedures above, if necessary, and remove the ignition timing assembly, alternator rotor and starter drive, and the clutch assembly.
4. Remove the starter motor.
5. Remove the spring guide and return spring from the kickstarter shaft.
6. Remove the two bolts and the oil seal holder.

7. Remove the two screws which secure the gear switch body.
8. On shaft-drive models, remove the secondary drive and driven gear boxes from the crankcase.
9. Remove the oil pump, gear shift mechanism, shifter cam plate and transmission shaft bearing retainers which are found beneath the clutch.
10. Remove the 11 or 12 upper crankcase bolts.
11. Turn the engine over and remove the oil pan and the lower crankcase bolts. The 8-mm bolts should be loosened gradually and in a cross pattern, starting at the center and working out towards the sides of the engine.
12. Separate the crankcase halves. If the cases are stuck, first check that all of the bolts have been removed. Then tap around the edges with a plastic mallet to unstick them.

Checking rod small end movement

Checking clearance between the flywheel and the rod big end

13. Lift out the crankshaft and connecting rod assembly.

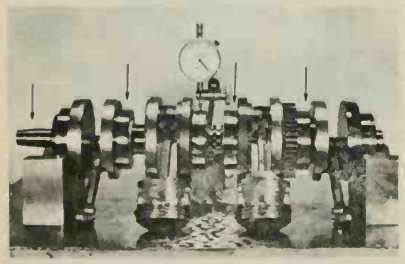
Inspection

1. The crankshaft is a pressed-together unit. Rod big ends ride in needle bearings. If

replacement of a rod or rod bearing or crankshaft bearing is necessary, the crankshaft will have to be disassembled. This work must be carried out by some one with the right tools and familiarity with the operation.

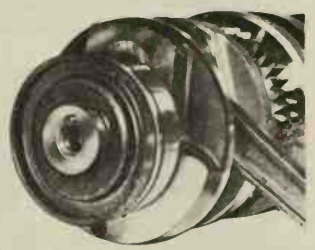
2. With a dial gauge, check rod side movement at the small end. Total deflection must not exceed 3 mm (0.14 in.). If it does, it indicates that the big end bearing is worn to the point of replacement.

3. With a feeler gauge, check the clearance between the connecting rod big end and the crankshaft flywheel. Standard clearance is 0.10—*0.55 mm (0.004*–0.026 in.). The serviceable limit is 1.0 mm (0.04 in.).



4. Mount the crankshaft in a set of v-blocks. With a dial indicator, measure crank run-out at the main bearings and crank ends. Standard maximum run-out is 0.03 mm (0.0012 in.). If run-out exceeds 0.06 mm (0.002 in.), the assembly must be replaced.

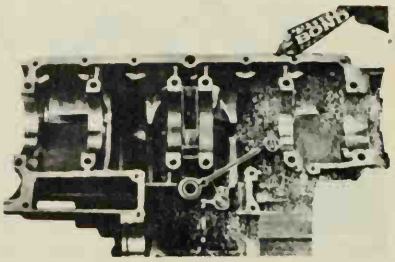
5. Check the condition of each crankshaft bearing by rotating them slowly and checking for unusual behavior. Bearing outer races must not be too loose. Rotation should be smooth, quiet, and effortless.



6. With a dial gauge, check the diametrical clearance of each crank bearing. Standard clearance is 0.015–0.040 mm (0.0006–0.0016 in.). Bearings which exceed 0.08 mm (0.0031 in.) must be replaced.

Assembly

1. Use new crankshaft oil seals. The right-side oil seal must be installed on the crankshaft as illustrated. Lubricate the seal lips before installation.



Check crank run-out at the points indicated

Be sure the bearing locating holes (B,C) are fitted to the pins (A,D)

Lower case half O-ring (A)

Crankcase bolt tightening order

2. When installing the crank assembly in the upper case half, be sure that each bearing is properly seated onto its locating pin.

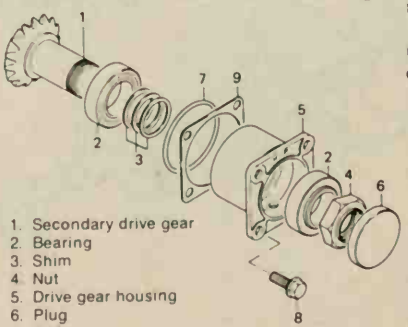
3. Be sure that the o-ring is installed in the lower case half. Refer to the illustration.

4. Apply Suzuki Bond #4 (Part No. 99000-31030) to the lower crankcase half mating surface.

5. After ensuring that the two case halves are correctly mated, install and tighten the 8-mm lower crankcase bolts. The bolts must be tightened gradually and in the order shown in the illustration (a cross pattern starting with the center bolts). Tighten the 8-mm bolts to 14.5 ft lbs.

6. Tighten the 6-mm crankcase bolts to 7.2 ft lbs.

7. Use a non-permenent thread-locking compound on the bearing retainer plate screws.



SECONDARY DRIVE GEAR

Disassembly

1. Knock the end plug out of the housing with a drift.

2. Bend back the shaft nut locktab. Hold the shaft in position, and remove the nut.

3. Use a plastic mallet or wood block and hammer to tap the drive gear out of the housing.

4. Remove—and save—the drive shaft shims.

5. Remove the inner bearing from the drive gear. A gear puller must be used.

6. Drive the bearing out of the housing.

Inspection

1. Check the bevel gear teeth for pitting, wear, or chips.

2. Closely check the tapered roller bearings for scored, worn, or overheated (bluish) rollers. Check for damage to the cage. Check that the bearing races are smooth and featureless.

NOTE: *If the bevel (drive) gear is damaged, the driven gear with which it meshes must also be replaced.*

Assembly

1. Install the outer bearing in the housing.

2. Install the inner bearing on the shaft of the bevel gear.

3. Install all of the original shims on the shaft.

4. Install the drive shaft into the housing and install the other bearing. Lubricate the bearings with SAE 90 gear oil.

5. Using a new shaft nut, secure the shaft in place and tighten the nut to 87–109 ft. lbs.

Preload Adjustment

After the drive gear assembly has been put together, the tapered roller bearings must be checked and, if necessary, adjusted.

1. Use a small torque wrench to determine how much torque is required to rotate the gear shaft.

2. The proper specification is 2.60–4.35 in lbs.

Turn the shaft around in both directions several times before making this check in order to seat the bearings.

3. If the torque is below specification (i.e. the shaft turns too freely), decrease shim thickness.

If the torque is greater than the specification, increase shim thickness.

Shims are available in numerous increments from 1.60–2.00 mm.

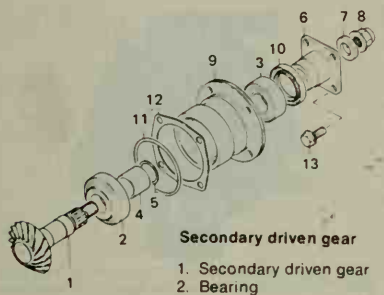
Be sure to reotate the shaft in both directions before each preload check.

4. After preload is correctly adjusted, remove the drive gear nut, clean and degrease the threads, and refit the nut tightening it to the correct torque (87–109 ft. lbs.).

5. Bend the collar of the nut over into the notch in the drive gear shaft.

6. Press a new plug into the housing so that it is 1.5 mm below the housing shoulder.

7. See "Clearancing Operations," below.



SECONDARY DRIVEN GEAR

Disassembly

1. Bend down the locktab and remove the driven gear nut.

2. Remove the flange. Remove the oil seal.

3. Remove—and save—the shaft shims and spacer.

4. Use a puller to take off the inner bearing. Drive the other bearing out of the housing.

Inspection

1. Check the gear teeth for pitting, wear, or chips.
2. Closely inspect the tapered roller bearings for scored, worn, or overheated (bluish) rollers. Check for damage to the cage. Check that the bearing races are smooth and featureless.

NOTE: *If the driven gear is damaged, the drive gear with which it meshes must also be replaced.*

3. Use a new oil seal on assembly.

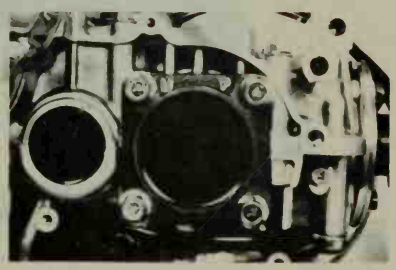
Assembly

1. Assembly is the reverse of disassembly. Install the bearings and the spacer and shims which were removed. Lubricate the bearings with SAE 90 gear oil. Do *not* install the oil seal until bearing preload is adjusted.
2. Use a new shaft nut and tighten it to 65–80 ft. lbs.

Preload Adjustment

1. Turn the shaft several times in either direction to seat the bearings.
2. Use a small torque wrench to determine how much torque is necessary to turn the shaft. It should be 3.45–6.05 in lbs.
3. If the required torque is under the given specification, decrease shim thickness.

If the shaft torque is above the specification, increase the shim thickness.



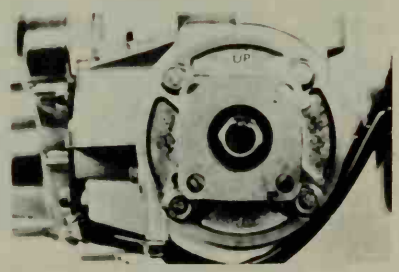
NOTE: *After changing shims, be sure to turn the shaft in both directions several times before rechecking preload.*

4. Shims are available in several increments from 1.60–2.00 mm.
5. After preload is correct, remove the nut, washer, and propeller shaft flange. Fit a new oil seal making it flush with the housing shoulder.
6. Degrease the shaft threads. Coat them lightly with a non-permanent thread-locking compound. Install the shaft, washer, and nut.

Torque the nut to 65–80 ft. lbs.

7. Bend the collar of the nut into the notch in the driven gear shaft.
8. Refer to "Clearancing Operations," below.

Clearancing Operations



Install the drive gear housing with "UP" in the proper position

1. Fit the housing shims—without o-rings—onto the housings. Install the housings on the crankcase.

NOTE: *Be certain that the housings are installed with the "UP" side correctly located.*

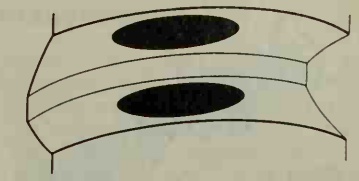
2. Tighten the housing bolts to 15–19 ft. lbs.
3. Fit a dial gauge to the secondary driven gear flange and check backlash.

It should be 0.08–0.13 mm (0.003–0.005 in.).

Install the driven gear housing with "UP" in the proper position

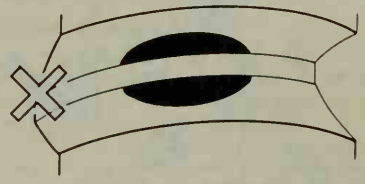
4. If backlash is not correct, the shim between the secondary driven gear housing and the crankcase must be changed.

If backlash is too low, increase shim thickness.



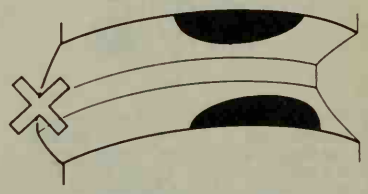
If backlash is too high, decrease shim thickness.

Shims are available in 0.35, 0.40, 0.50, and 0.60 mm thicknesses.



5. After backlash is corrected, tooth contact must be checked.
6. Remove the secondary driven gear housing. Clean and degrease the gear teeth and coat several of the teeth with machinists dye. Reinstall the housing with the correct shim and tighten the bolts to 15–19 ft. lbs. It is not necessary to use the o-ring.
7. Shift the transmission into 1st gear and turn the driven gear flange several turns in both directions. Remove the driven gear housing and observe the tooth contact patterns.
8. Refer to the illustration of tooth contact patterns. If contact is correct, refer to "Final Assembly," below. If not, proceed as follows:
9. If tooth contact pattern is incorrect, the shim between the drive gear housing and the crankcase must be changed.

If the contact is at tooth top, decrease shim thickness.



If contact is at tooth roof, increase shim thickness.

Correct tooth contact pattern

Contact at tooth top (increase shim thickness)

Contact at tooth roof (decrease shim thickness)

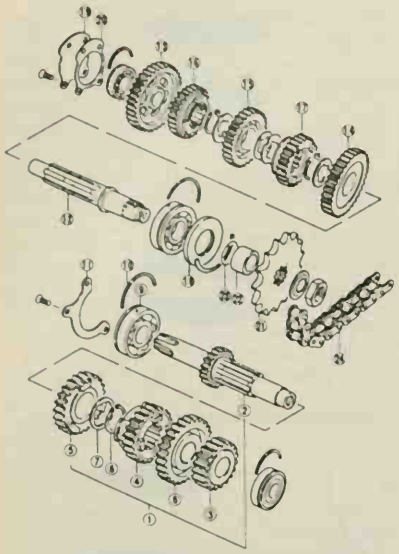
Shims are avilable in 0.35, 0.40, 0.45, and 0.50 mm sizes.

NOTE: *After adjusting tooth contact, recheck backlash.*

FINAL ASSEMBLY

1. After tooth contact and gear backlash are both correct, remove the two housings from the crankcase.
2. Clean the gears thoroughly and coat them with gear oil.
3. Use new o-rings on the housings and oil lightly.
4. Fit the housings, noting that the "UP" side is marked. Use a non-permanent thread locking compound on the housing bolts and tighten them to 15–19 ft. lbs.
5. Tighten the drain plug to 15–22 ft. lbs. Do not forget to add oil. Capacity is 11.0–13.5 oz (340–400 cc) of SAE 90 EP hypoid gear oil.

TRANSMISSION (750)



Disassembly

1. Separate the crankcase halves as described above under "Lower End."
2. Pull out the shift fork shafts and remove the shift forks and cam stopper.
3. Remove the shift drum stopper spring holder and take out the pin and spring. Remove the shift drum.

Inspection

NOTE: *Do not disassemble the gear set unless inspection shows that replacement of individual gears is necessary. Gear shaft circlips are not reusable and must be replaced with new ones whenever the gear set is taken apart.*

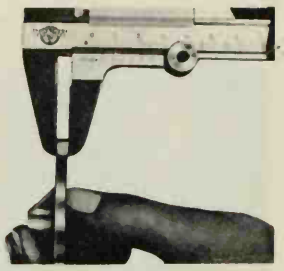
lay out each piece in the order it is removed to facilitate reassembly.

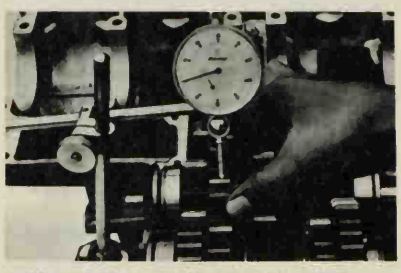
1. Flush the transmission shaft bearings with clean motor oil and check operation. Bearing rotation must be smooth, effortless, and quiet. There must be no play between the inner and outer bearing races. If damage is noted, replace the bearings as a set.

2. Install the countershaft and mainshaft assemblies in the crankcase and measure gear backlash with a dial gauge. "Backlash" is the amount of movement noticeable in a gear when the gear with which it meshes is locked in place.



For 1st, 2d, and 3rd gears, standard backlash is 0.04 mm (0.002 in.) or less. The serviceable limit is 0.1 mm (0.004 in.).

For 4th and 5th gears, standard backlash is 0.05–0.1 mm (0.002–0.004 in.). The serviceable limit is 0.15 mm (0.006 in.)



Note that gears are always replaced in pairs.

3. Check the gear teeth for damage, wear, or pitting. Pay close attention to the very base of the teeth. Gears are surface-hardened, and if this hardened layer is damaged, what is left will not last long. Check the engaging dogs and/or dog slots on each gear for chipping or wear. Check that splined gears are a good fit on their shaft (neither too loose nor too tight) and that the splines on the shafts and on the gears are in good condition. Check that gears with plain bores can rotate freely but are not too loose on their shafts. Check all parts for damage due to overheating or lack of lubricant.

4. Check the shift forks for wear or chipping to the fingers or pin. Measure the thickness of the fingers. Standard thickness is 4.95–5.05 mm (0.195–0.199 in.). The serviceable limit is 4.85 mm (0.191 in.).

distorted or worn to the point that the kickstarter lever cannot be properly secured.

10. Check the kickstarter gears for wear or damage to the teeth.

Assembly

1. If the kickstarter shaft has been disassembled, be sure to align the punch marks on the kick drive gear with that on the shaft.

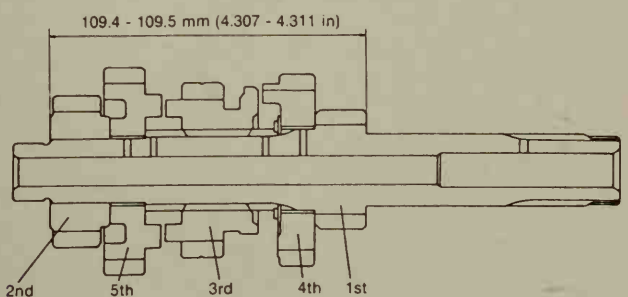
2. When installing the shift forks, note that the shift fork for the 3rd gear is different from those for 4th and 5th gears. The fork for the 3rd gear is installed on its own shaft. Refer to the illustrations.

3. If the gear clusters have been disassembled, refer to the exploded view for correct component locations. New circlips should always be used.

Note the special washers installed between the 5th and 3rd gears on the mainshaft. Install the washers so that the tabs in the one match the grooves in the other.

4. The countershaft 2d gear must be pressed onto its shaft. Fit this gear so that the distance between the 1st countershaft gear and the 2d countershaft gear is 109.4–109.5 mm (4.307–4.311 in.). Refer to the illustration.

NOTE: *The 2d countershaft gear should be installed with a bearing locking compound. Be sure that the locking compound does not spread to the adjacent gear.*



5. Be sure that the O-ring is fitted to the mainshaft right-side bearing.

6. The countershaft left-side bearing and the mainshaft right-side bearing are installed with the oil seal sides facing outward.

7. Be sure that the bearing dowel pins are fitted to the cut-outs provided when installing the shafts.

8. The remainder of the assembly procedure is the reverse of disassembly. Refer to the "Lower End" section, above, for the crankcase mating procedure.

Be sure to use a thread locking compound on the bearing retainer plates.

TRANSMISSION (850)

NOTE: *Inspection procedures and specifications for the gears and shift mechanism of the 850 is the same as for the 750 described in the previous section. Before dismantling the gear shafts, refer to "Inspection" for the 750 transmission.* Kickstarter service for models so equipped can also be found in the 750 section.

Disassembly

1. To disassemble the countershaft (which is the transmission shaft with the shock absorber spring), first remove the bearing on the spring side and also the spacer.

CAUTION: *When disassembling transmission shafts, be sure to lay each component out in the order in which it was removed to facilitate assembly.*

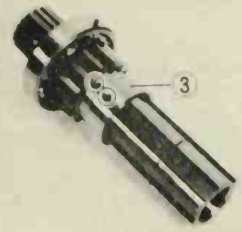
3. Carefully remove the other gear components noting location and direction of installation on the shaft.

4. The mainshaft is easily disassembled after removal of the bearings and circlips.

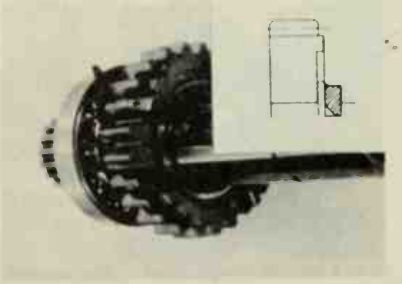
Inspection

See "Inspection" under "Transmission (750)," above.



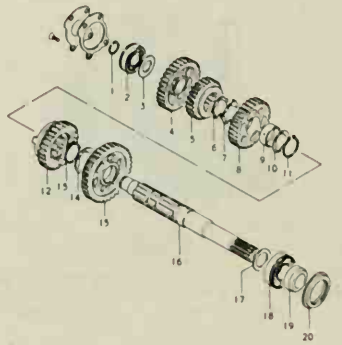
Assembly

1. Always use circlips where applicable.



2. Note direction of mounting of gears.

3. Clean all metal components in solvent before mounting. Lubricate inner surfaces of gears before installing them on their shafts.



4. Refer to the exploded illustration of the transmission shafts. Note also the following points.

Always align oil holes in shafts, bushings, and gears

Be sure that the circlip is properly installed

5. On the countershaft, align the hole in the shaft with the hole in the spacer when it is fitted.

6. Be sure that the locating washer is fitted to the spacer dogs. Install the circlip to the side where the thrust is as shown in the illustration.

7. Be sure that the oil hole in the 3rd gear shift fork groove aligns with the oil hole in the countershaft. The same holds true of the 5th gear spacer. Also be sure that the spacer faces the proper direction.

8. Use moly paste on both sides of the washer fitted after the 2d gear and to the area of the outer countershaft bore 20–30 mm (0.8–1.2 in.) from each end of the shaft. Oil bearing surfaces.

9. Install the inner shaft into the outer. Mount the output cam dog on the outer shaft. Align the cutout on the cam dog with the oil hole in the countershaft.

10. Apply moly paste to the splines of the input cam dog and mount it on the inner countershaft.

11. Mount the spring, guide, and sliding stopper. Compress the spring and fit the stoppers.

12. For the mainshaft, the same precautions hold true. Be sure that the components are installed in the proper order facing the right direction.

13. After installing the 4th driven gear, install the circlip, then the washer. Temporarily position the circlip beyond the groove. Align the hole in the spacer with that in the shaft. Fit the 3rd gear.

14. Install the lockwasher, then the washer and turn the washer to align the lockwasher tongue with the washer cutout.

15. Fit the circlip installed earlier into its groove. Install it as shown in the illustration.

16. Align the oil hole in the 5th gear shift fork groove with the hole in the mainshaft.

LUBRICATION SYSTEM

CHECKING OIL PRESSURE

1. Be sure that the engine has the proper quantity of oil (between the "F" and "L" marks on the inspection window).
2. Start the engine and run it until oil temperature reaches about 60° C (140° F).
3. Remove the oil gallery plug at the right side of the engine just below the cylinders and install the special oil pressure gauge.
4. Start the engine and run it at about 3000 rpm while checking the gauge reading. Oil pressure should be about 1.42 psi or more (0.1 kg/cm²).
5. If the oil pressure is below this limit, remove and inspect the oil pump internals.
6. When fitting the oil gallery plug, be sure to secure it with a non-permanent thread-locking compound. Tighten the plug securely.

OIL PUMP

Removal

1. The oil pump is located just behind the clutch. "Engine and Transmission," for clutch removal procedures.
2. Remove the three securing screws and take off the oil pump.

Disassembly

1. Remove the circlip and pull off the pump gear.
2. Remove the securing screw.
3. Drive out the pins towards the transmission side of the pump.
4. Separate the pump case halves and take out the internals.

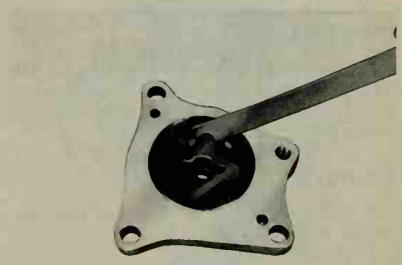
Inspection

1. Clean all parts thoroughly in a solvent.
2. Check the clearance between the inner rotor tip and the outer rotor. It must be 0.2 mm (0.008 in.) or less.
3. Check the clearance between the outer rotor and the pump body. It must be 0.25 mm (0.0098 in.) or less.
4. Place a straight edge across the pump body and check the side clearance between the straight edge and the sides of the rotors. Side clearance must be 0.15 mm (0.0059 in.) or less.
5. If any of the above clearances are not within the given specifications, the oil pump must be replaced.

Assembly

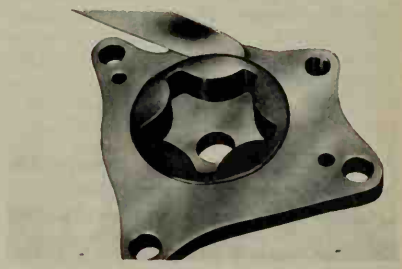
Assembly is the reverse of disassembly. Lubricate all internal components with clean engine oil before assembly. Apply a non-permanent thread-locking compound to the securing screw.

Installation



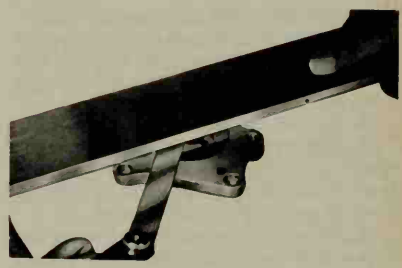
1. Be sure that the two o-rings are in place behind the oil pump. The use of new o-rings is recommended.
2. Secure the three oil pump mounting screws with a non-permanent thread-locking compound.

OIL FILTER SCREEN



The oil filter screen should be cleaned every 6,000 miles, or about once a year.

The filter screen is easily reached after removing the exhaust pipes and the oil pan.



Use a new oil pan gasket on assembly. Be sure to tighten the pan bolts evenly to avoid distortion. Tighten the pan bolts to 7.2 ft lbs.

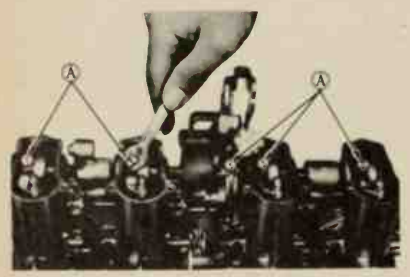
FUEL SYSTEM

VM26SS CARBURETOR OVERHAUL

The following procedures apply to the VM26SS standard throttle slide carburetors found on all models except the GS 850/GLT which use CV units.

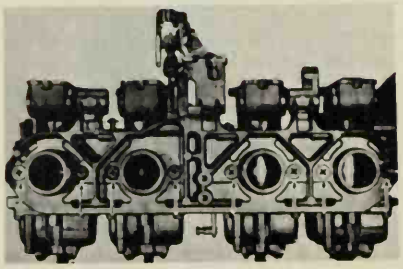
Removal

The carburetors must be removed from the engine as an assembly.



1. Remove the gas tank.
2. Remove the air cleaner and the air cleaner box.
3. Disconnect the overflow lines from the from the linkage. Disconnect the choke cable, if fitted.
4. Loosen the securing clamps and pull the carburetors off the manifolds.
5. Drain the carburetor float bowls.

Installation



1. Installation is the reverse of removal.
2. Adjust the throttle cable free-play after connecting the cables. Be sure that all lines are tightly secured. Check for fuel leaks before starting the engine.

Disassembly

1. It is not necessary to separate the carburetors from their mounting plate to service the float bowl components and jets. This step is only necessary if the throttle slide is to be removed.
2. Remove the four carburetor caps.
3. Remove the five bolts which secure the throttle shaft. Four of the bolts are found beneath the carburetor caps, and the fifth secures the pulley to the throttle shaft.
4. Remove the screw which secures the stopper plate just to the right of the leftmost carburetor, and remove the stopper plate.
5. Pull out the throttle shaft.
6. Remove the four choke shaft screws. Remove the spring-loaded screw in the choke actuating lever slot. Pull out the choke shaft.
7. Remove the screws (2 ea) which secure the carburetor bodies to the mounting plate. Separate the carburetors.
8. Lift out the throttle arm complete with the throttle slide assembly. If replacement or repositioning of the needle is desired, remove the two screws which secure the throttle slide bracket to the slide.
9. Unscrew and remove the pilot air screw, its o-ring and spring.
10. Unscrew and remove the starter plunger assembly.

11. Turn the carburetor upside down and remove the four float bowl retaining screws. Take the float bowl off carefully to avoid damage to the floats. Remove the float bowl gasket.
12. Unscrew and remove the main jet. Unscrew and remove the main jet holder/emulsion nozzle.
13. Unscrew and remove the pilot jet.
14. Push out the float pin and remove the float bulbs. Take out the float needle. Unscrew and remove the float needle seat.
15. Press out the needle jet from the carburetor bore side.

Cleaning

The carburetors have non-removeable plastic parts. Clean the body only in a solvent or carburetor cleaner which is safe for plastic. Blow all air and fuel passages clear with compressed air.

Clean the fuel jets in a solvent and blow them clear. Never insert anything into the jet bores to clear them if they are clogged as this risks ruining their calibration.

Inspection

1. Check the throttle slide surfaces for scoring or signs of wear. The slide should be smooth. The movement of the slide in the carburetor body should be very easy.
2. Examine the jet needle for wear along

the tapered portion as indicated by bright spots or unevenness of the taper. Also check the needle for nicks, and replace it if any damage is noted. Be sure that the needle clip is repositioned in the original groove.

3. After many miles, the needle and needle jet should be replaced, as these parts are subject to wear. Wear of these components may show up as a rich running condition in the mid-throttle range. If the needle seems worn, it would be best to replace the needle jet as well.

4. Check the float needle for wear of the tip or foreign matter and replace if necessary. Check the needle seat for corrosion or foreign matter. Clean off the seat if only dirty. Corroded needle seats should be replaced.

5. Check the carburetor body and the float bowl for stress cracks.

6. Inspect the pilot air screws. The taper of the screws should be very even. Replace if the screw tip is blunted.

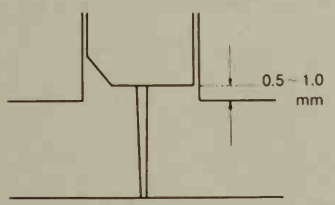
Assembly

Assembly is basically the reverse of disassembly. Note the following points:

1. Use new gaskets and o-rings.

2. Do not overtighten the jets when fitting them to the carburetor body.

3. Check the float height.



4. On 1977 models only, screw the pilot screws in until they are lightly seated, then back them off 1¼ turns. Other models have preset pilot screws.

5. Check that the needle clip is positioned in the proper groove.

6. The screws which mount the carb bodies to the mounting plate should be secured with a non-permanent thread-locking compound.

7. Grease the throttle shaft and the lips of the throttle shaft seals before installing the shaft. Tighten the throttle shaft bolts to 2.5 ft lbs.

8. After the carburetors have been mounted on their plate, adjust the full-throttle stopper as follows: back off the idle adjuster screw until there is some clearance between the end of the screw and the pulley. Loosen the throttle slide adjusting screw locknuts and back off the adjusting screws so that the throttle slides are completely closed. This adjustment should be made carefully so that all four carburetors are as close as possible. Open the throttles as far as possible. Adjust the full-throttle stopper so that when this is done, the bottom edge of the slides will be 0.5–1.0 mm (0.02–0.04 in.) above the top of the carburetor bore, as illustrated. After installation has been completed, synchronize the throttle slides as outlined in the "Tune-Up" chapter.

Adjust the full-throttle stopper so that the slides can be lifted 0.5–1.0 mm above the edge of the carburetor bore

Full-throttle stopper (B)

VM32SS CARBURETOR OVERHAUL

The VM32SS constant-velocity (CV) carburetor is used on the GS 850GT/GLT motorcycle. Unlike the standard carburetors in which the throttle slides are controlled directly by cable and linkage, the CV carburetor features a throttle plate controlled by the cable and twist-grip. This plate varies engine vacuum which itself determines the movement of the throttle slide.

Removal

1. Remove the gas tank.

2. Remove the air cleaner and the air cleaner box.

3. Disconnect the overflow lines from the carburetors. Disconnect the throttle and choke cables.

4. Loosen the securing clamps and pull the carburetors off the manifolds.

5. Drain the float bowls.

Installation

1. Installation is the reverse of removal.

2. Be sure that all fuel lines are tightly secured and fitted with their safety clips. Check that cable and line routing is correct.

3. Be sure that the carburetors are pushed onto the manifolds as far as possible before the clamps are tightened.

4. Adjust the control cables and check the system for fuel leaks before starting the engine.

Disassembly

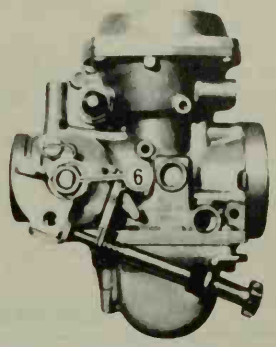
Separation of the carburetors is only necessary if a complete overhaul is necessary. Most of the main metering components are accessible after removing the float bowl or carburetor cap. If routing cleaning is being carried out, this is all that is usually necessary. For complete disassembly, proceed as follows.

1. Remove the screws which secure the throttle cable and choke lever brackets.

2. Loosen the four choke shaft screws, remove the shaft, levers and choke bracket and lever.

3. Remove the upper carburetor mounting bracket screws.

4. Remove the lower carburetor mounting bracket screws. Separate the carburetors.



5. Remove the idle adjusting screw lever nut and the lever. Remove the idle adjusting screw assembly.

6. Remove the float bowl screws and carefully take off the float bowl. If it is stuck, tap it lightly with a screwdriver handle or the like while holding it in place.

7. Push out the float pivot pin and remove the float assembly.

8. Remove the float needle. Unscrew and remove the float needle seat.

9. Unscrew and remove the main jet. Note the washer beneath it.

Idle adjusting screw lever nut (6)

10. Remove the plug. Unscrew and remove the pilot jet.

11. Unscrew and remove the carburetor cap screws. Remove the cap, spring, and throttle slide assembly.

12. Push out the needle jet.

Cleaning

Clean the carburetor body in clean solvent designed for this job and which is safe for plastic parts.

Blow all air and fuel passages clear with compressed air.

Do not allow carburetor cleaner or any other solvent to contact the throttle slide diaphragm.

Clean the fuel jets in a solvent and blow them clear. Never insert anything into the jet bores to clear them if they are clogged as this risks ruining their sensitive calibration.

Inspection

1. Check the throttle slide diaphragm for punctures or tears. The slide must be replaced if damage is evident.

2. Check the throttle slide surfaces for scoring or signs of wear. The slide should be smooth. The movement of the slide in the carburetor body must be very easy and without binding.

3. Examine the jet needle for wear along the tapered portion as indicated by bright spots or unevenness of the taper. Also check the needle for handling damage such as nicks and replace it if any damage is noted.

4. After many miles, the needle and needle jet should be replaced, as these parts are subject to wear. Wear of these components may show up as a rich running condition in the mid-throttle range. If the needle seems worn, it would be best to replace the needle jet as well.

5. Check the float needle for wear of the tip or foreign matter and replace if necessary. Check the needle seat for corrosion or foreign matter. Clean off the seat if only dirty. Corroded needle seats should be replaced.

6. Check the carburetor body and the float bowl for stress cracks.

7. Clean the mesh filter on the end of the needle seat.

Assembly

Reverse the disassembly procedure and note the following points:

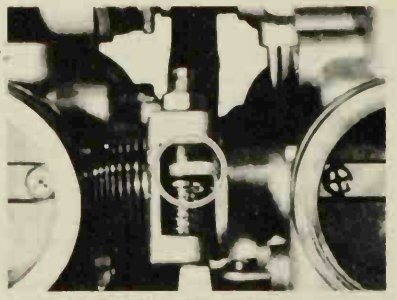
1. Always use new gaskets and o-rings.

2. Be sure that the throttle slide diaphragm is properly seated in the groove provided and that the locating tab of the diaphragm is fitted into the cutout.

3. Do not overtighten the jets when screwing them into the carb.

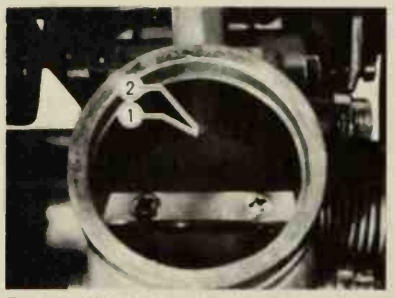
4. Check float height (see "Tune-Up").

5. Use a non-permanent thread locking compound on the idle adjusting bracket screws of the No. 3 carb.



6. Use a non-permanent thread locking compound on the upper and lower carburetor mounting bracket screws.

7. Be sure that the throttle shaft lever is installed as illustrated.



8. Non-permanent thread locking compound should be used on the choke shaft screws. These screws also fit tapered ends into countersinks in the shaft. Be sure they are correctly aligned.

9. After assembly is completed, and before the units are installed, perform a rough synchronization of the throttle valves by aligning the edge of each valve with the first bypass hole in the carb throats.

10. After installatcon, check float level and synchronize units. Adjust idle. Refer to "Tune-Up."

ELECTRICAL SYSTEM

CHARGING SYSTEM

Alternator Output Test

The following test should be carried out if the battery fails to charge or overcharges. Before attempting the test, note the following:

a. Check the condition of the battery with a hydrometer. Test results will not be valid if the battery is defective. The battery must be *fully* charged. Charge the battery before beginning the test if it is not.

b. Check that all electrical connections are clean and tight. Check that the rectifier and regulator are properly mounted.

1. Remove the headlight switch knob and shut off the headlight or remove the 10A light fuses.

2. Raise the seat to gain access to the wiring connections. Disconnect the yellow wire from the regulator.

3. Disconnect the white/green alternator lead and the white/red rectifier lead and connect the two together.

4. Connect a DC voltmeter across the battery.

5. Making sure that all lights are off, start the engine and run it at a steady 5000 rpm while making note of the voltmeter reading. The voltmeter must read at least 17 volts. If it does, it shows that the alternator and rectifier are in serviceable condition. If the voltage reading is less than 17 volts, either the alternator or the rectifier or both are faulty. Procede to the components tests following.

If the voltage reading is satisfactory, the problem is probably the regulator. Test it as described below.

Regulator/Rectifier

While early models have separate regulator and rectifier units (see illustration), all others have both functions combined in a single sealed unit.

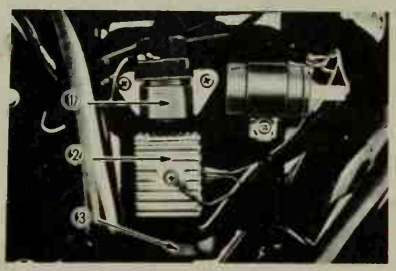
The regulator/rectifier can be tested with a simple continuity tester.

1. Disconnect all of the rectifier/regulator leads.

2. Put the positive probe of the tester on the red lead, and the negative probe on the yellow, white/blue, white/red, and black/white leads in turn.

There must be continuity in each case. Now reverse the probes. There must be no continuity.

3. Put the negative probe of the tester on the black/white lead, and the positive probe on the yellow, white/blue, and white/red leads in turn.



There must be continuity in each case. Now reverse the probes. There must be no continuity.

4. Connect the positive probe to the black/white lead and the negative probe to the yellow lead. The tester should show continuity.

5. Now connect the positive probe to the yellow, white/blue, white/red, and black/white leads in turn while the negative probe is connected to the red lead. There should be no continuity.

6. Connect the positive probe to the black/white lead and the negative probe to the white/blue and white/red leads in turn. There must be no continuity.

If the regulator/rectifier fails to pass any of the continuity tests in Steps 2–6, it must be replaced.

Starter solenoid (1), rectifier (2), regulator (3)

Regulator Test

1. For the test to be valid, the battery must be in good condition and fully charged as for the alternator test just described. Be sure all electrical connections are clean and tight.

2. If the alternator output test outlined above has been carried out, reconnect all wiring to its original condition.

3. Connect a DC voltmeter across the battery terminals.

4. With all lights shut off, start and run the engine at 5000 rpm while noting the voltmeter reading.

5. The voltmeter must read at least 14.0–15.5 volts (or more). If it does not, and the alternator/rectifier test above indicates that those two components are satisfactory, it indicates that the regulator is at fault and must be replaced. No repairs are possible.

NOTE: *Electrical components are supplied by two manufacturers (Denso or Kokusan). When replacing parts, be sure that all are of the same make.*

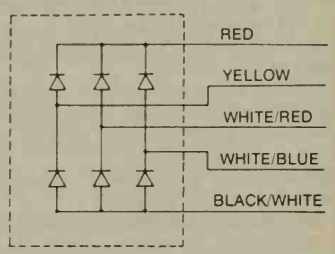
Alternator Test

The alternator stator can be checked with a continuity tester or an ohmmeter.

1. Disconnect the three alternator leads (white/green, white/blue, yellow).

2. Check for continuity between each lead and the others. There must be continuity in each case. No continuity indicates a broken wire and necessitates replacement of the stator.

If an ohmmeter is being used, there should be about 0.65 ohms resistance between the leads. Too great or too low a resistance reading is indicative of stator damage and requires replacement of the unit.



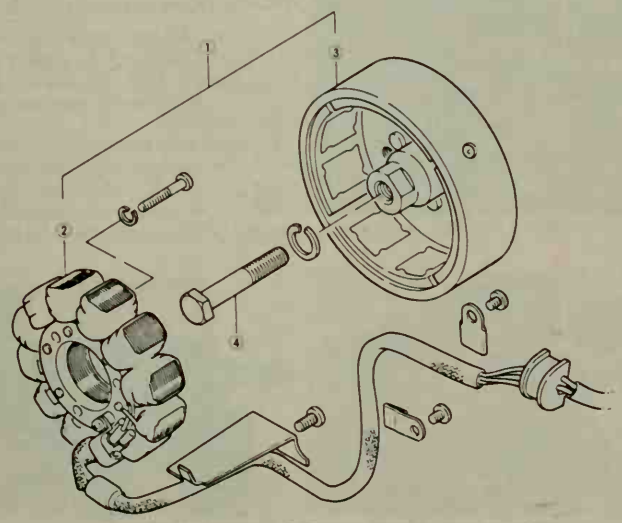
3. Check for continuity between each of the alternator leads and the stator body. There must be *no* continuity here. If there is, it indicates an internal short which will necessitate replacement of the stator.

3. Check for frayed or stripped wires and repair them if found.

NOTE: *If replacement of the stator is necessary, make sure that it is of the same manufacture (Denso or Kokusan) as the rotor.*

Rectifier Test

The rectifier consists of six diodes arranged to produce full-wave rectification of the alternator's output into direct current.



Rectifier wiring

All six diodes must be tested and all six must function properly or the unit will require replacement.

The rectifier can be checked with either a continuity tester or an ohmmeter.

CAUTION: *Do not use a megger.*

1. Disconnect all of the rectifier leads. They are: yellow, white/red and white/blue from the alternator; red from the battery; and black white from ground.

Alternator assembly (1), stator (2), rotor (3), rotor bolt (4)

CAUTION: *Be sure that all of the leads are disconnected, especially the red output wire or the rectifier may be damaged during the test.*

2. Place one lead of the continuity tester or ohmmeter on the red lead's terminal and the other to the yellow, white/red, and white/blue leads in turn. Note whether or not there is continuity or not.

Now reverse the tester leads and make the check with the same wires. Note whether there is continuity or not.

There must be continuity in one direction only. If there is continuity in neither direction, or in both directions for any of the diodes, the rectifier must be replaced.

3. Carry out the same tests between the yellow, white/red, and white/blue leads and the black/white (ground) terminal.

Once again, there must be continuity and in only one direction for each lead tested or the rectifier must be replaced.

BREAKER POINT IGNITION SYSTEM

The ignition system consists of the battery, breaker points, coils, condensers, spark plug caps, and spark plugs.

There are two sets of breaker points and two ignition coils. Each coil fires two cylinders. They are paired No. 1 and 4, and No. 2 and 3.

1. In the event of failure of the ignition system, first check the fuses, if all are in working order, check that the snap connectors for the coils and breaker points are all clean and tight.

2. At this point refer to inspection procedures for the breaker points, plugs, and battery. If these items are all in working order, the problem may be isolated to the coils, condensers, or plug caps.

3. If only one cylinder fails to fire, and the problem is not a loose connection or defective spark plug, suspect the plug cap. The caps are fitted with a resistor to prevent radio interference while in operation, and heat and vibration may cause the value of this resistor to increase considerably, even to becoming an open circuit.

The easiest way to see if a misfire is due to a defective cap is to switch the plug lead of the non-firing cylinder with its corresponding cylinder (1–4, 2–3). If the dead cylinder begins to fire and the other cylinder ceases, the problem is the plug cap. The caps should be replaced as a set.

Functional caps will have a resistance of 5,000–7,500 ohms. Usually, when resistance reaches about 9,000 ohms, the plug for that cap will no longer fire.

Caps are easily removable by unscrewing them from their cables.

4. Defective condensers are seldom a problem, since these are now usually replaced along with the breaker points. Defective condensers will cause considerable arcing or sparking between the breaker point contacts while the machine is running, and this should be cause for replacement before they fail completely. Badly burned or pitted point contact surfaces can also be caused by defective condensers, as well as by improper adjustment. If the points are in bad condition, replace them and the condensers as well.

5. Condenser capacity can be checked with electrical test equipment (if available) provided the condenser is first disconnected from the breaker plate.

Capacitance should be 0.25 MFD for Kokusan condensers and 0.18 MFD for Denso condensers.

6. If the condensers are not suspect, check the ignition coils. Coils can be checked for continuity of the windings. Check for continuity between the two low-tension wires. Resistance should be about 4 ohms. If there is no continuity, the primary winding is broken and the coil must be replaced.

Check for continuity on the high-tension side of each coil. Resistance is c. 15K ohms. Disconnect the two spark plug leads of one of the coils and check the continuity between them. If none exists, replace the coil. Repeat the test with the other coil. Remember you will be checking continuity between plug leads 1 and 4 and leads 2 and 3.

TRANSISTORIZED IGNITION SYSTEM

1. Disconnect the signal generator wires at the plastic coupler. Check resistance between the blue and green leads on the signal generator side. Standard resistance is 250–360 ohms.

2. If the signal generator resistance is satisfactory, remove the Nos. 1 and 2 spark plugs, connect them to their caps, and ground them against the cylinder head.

3. Remove the left side frame cover. Disconnect the signal generator leads at the coupler.

4. Turn the ignition switch "on." Connect the positive probe of an ohmmeter (set to the ohms x 1 range) to the blue lead of the *ignitor* side of the circuit, and the negative probe to the green lead, also on the ignitor side. The moment the probes are connected, the No. 1 plug should fire. The moment the probes are disconnected, the No. 2 plug should fire. If this happens, the ignitor is in workable condition.

5. Other parts of the system, such as plugs, plug caps, and ignition coils, are the same as described for the "Breaker Point Ignition System," above. Refer to that section if the electronic components check out and the problem persists.

STARTING SYSTEM

The starting system consists of the starter motor and clutch, the solenoid, and the handlebar-mounted starter switch. When the button is pressed, the electrical circuit to the solenoid is closed and the solenoid is activated, sending the battery current directly to the starter motor. The starting system is quite reliable and it is unlikely that any major problems will arise.

Testing

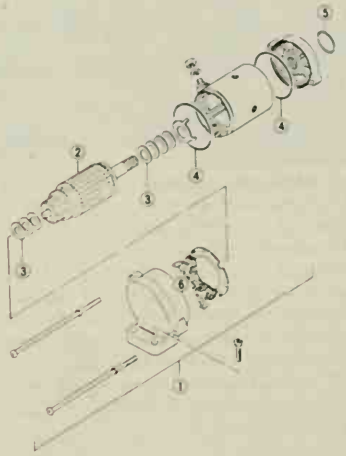
1. If, when pressing the starter button, the starter motor spins but the engine does not, the problem is probably the starter clutch. Refer to the "Engine and Transmission" chapter for removal procedures.

2. If the engine turns over very slowly, possible causes include cold weather and/or oil of too high viscosity, a low battery, or a defective starter motor.

3. If the engine fails to turn over and the warning lights dim when the starter button is pushed, causes may be a low battery or a defective starter motor.

4. If nothing at all happens when operating the starter button, check the button's electrical connections. If these are serviceable, suspect the starter solenoid.

5. A clattering sound when the starter button is operated may be caused by a defective solenoid or starter motor.



Starter Motor

REMOVAL AND INSTALLATION

1. Disconnect the cable from the battery positive terminal.

2. Disconnect the starter motor cable from the starter motor.

3. Remove the starter motor cover. Remove the alternator cover.

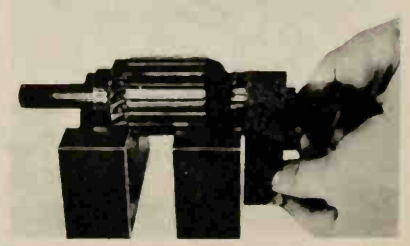
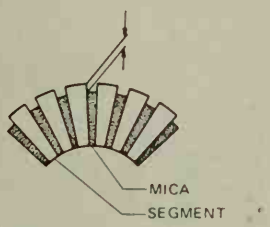
3. Shims
4. Oil seal
5. O-ring
6. Brushes

Starter assembly



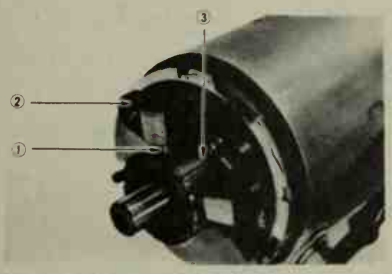
4. Remove the starter motor gear. Remove the mounting screws and take out the starter motor.

INSPECTION



Two makes of starter motor are used, Denso and Mitsuba. Although the starters are similar in appearance, some specifications differ.

1. Take out the two screws and remove the starter side cover.



2. Check electrical continuity between the commutator and armature core using a multitester or test light and battery. If continuity exists, the armature coil is grounded and the complete starter motor unit must be replaced.

Brush (1), brush spring (2) and commutator (3)

Mica undercut

Polishing the commutator surface

3. Check for continuity between all of the commutator segments. Continuity must exist in each case.

4. Check continuity between the brush that is wired to the stator coil and the starter motor cable. Lack of continuity indicates an open circuit in the stator coil, and the starter motor unit should be replaced.

5. Examine the carbon brushes for damage to the contact surfaces and measure their length. Brushes must be at least 6 mm (0.24 in.) for Mitsuba starters and 9 mm (0.35 in.) for Denso starters. Standard brush length is 12–13 mm (0.47–0.51 in.) and 14 mm (0.55 in.) respectively.

6. The mica undercut of the commutator should be at least 0.2 mm (0.008 in.). The standard specification is 06 mm (0.02 in.). Any carbon deposits should be cleaned out of the commutator grooves, and a piece of hacksaw blade or the like used to increase the undercut depth if necessary. Refer to the illustration.

7. Polish the commutator with fine emery cloth and clean it thoroughly before installation.

STARTER SOLENOID

1. If the battery is in reasonably good condition, and nothing at all happens when the starter button is pushed, check the solenoid.

2. Disconnect the starter cable at the starter motor. When the button is pushed, there should be an audible "click" which indicates that the solenoid is opening.

3. If further testing is necessary, remove the solenoid from the machine.

CAUTION: *Be sure to disconnect the cables at the battery before disconnecting the solenoid terminals.*

4. Connect a fully charged 12-volt battery to the solenoid low-tension terminal and the solenoid mounting bracket. Check for continuity across the high-tension leads with an ohmmeter or self-powered test light. If there is no continuity, replace the solenoid.

5. If an ohmmeter is available, check the resistance of the solenoid's primary winding by placing on meter probe on the low-tension terminal and the other on the mounting bracket. Primary winding resistance should be in the neighborhood of 3.5 ohms. If it is not, replace the solenoid.

ELECTRICAL COMPONENTS

Switch and component tests can be carried in most instances with an ohmmeter or test light with a self-contained power source.

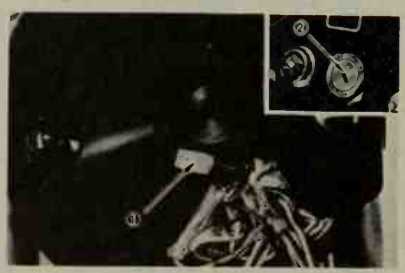
NOTE: *After disconnecting the switch, be sure you are testing the switch side of the circuit.*

Ignition Switch

The four-pronged ignition switch plastic connector is inside the headlight shell. After removing the headlight and disconnecting the connector, check for continuity between each of the leads while moving the switch to each position in turn.

When the switch is "off," there should not be continuity between any of the leads.

When the switch is "on," there should be continuity between the red and orange leads and between the gray and brown leads.

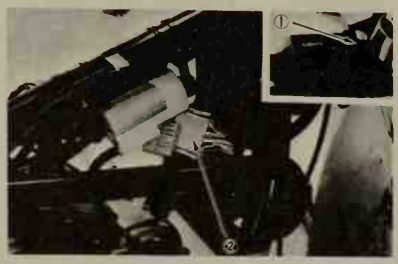


When the switch is in the "P" position, there should be continuity between the red and the brown leads.

If the switch does not pass all of the above tests, replace it.

Headlight Switch

The headlight switch coupler is accessible after removing the gas tank.



When the switch is in the "on" position, there should be continuity between the orange and the green wires and between the white/green and the white/red wires.

Ignition switch coupler

Checking resistance of the primary circuit

Lighting switch coupler

Dimmer Switch

The dimmer switch wiring is incorporated with the headlight switch coupler.

In the "L" position, there should be continuity between the white and the green leads.

In the "H" position, there should be continuity between the yellow and the green leads.

Front Brake Light Switch

Disconnect the white and orange switch leads inside the headlight shell. These leads should show continuity when the brake hand lever is operated.

Rear Brake Light Switch

Disconnect the white and orange leads from the switch and check for continuity across the switch terminals when the brake pedal is depressed. If there is none, try moving the switch on its bracket as far as possible. If there is still no reaction, replace the switch.

Horn and Horn Switch

If the horn fails to sound, the easiest way to check it is to disconnect the two wires at the horn itself and connect a 12-volt battery across the terminals. If the horn sounds, the switch is probably defective, barring loose connections in the circuit.

To check the horn switch, uncouple the large plastic connector beneath the gas tank and check for continuity between the green and black/white wires when the horn button is operated. There should be continuity. If there is not, there is undoubtedly a loose wire in the circuit.

Turn Signal Switch

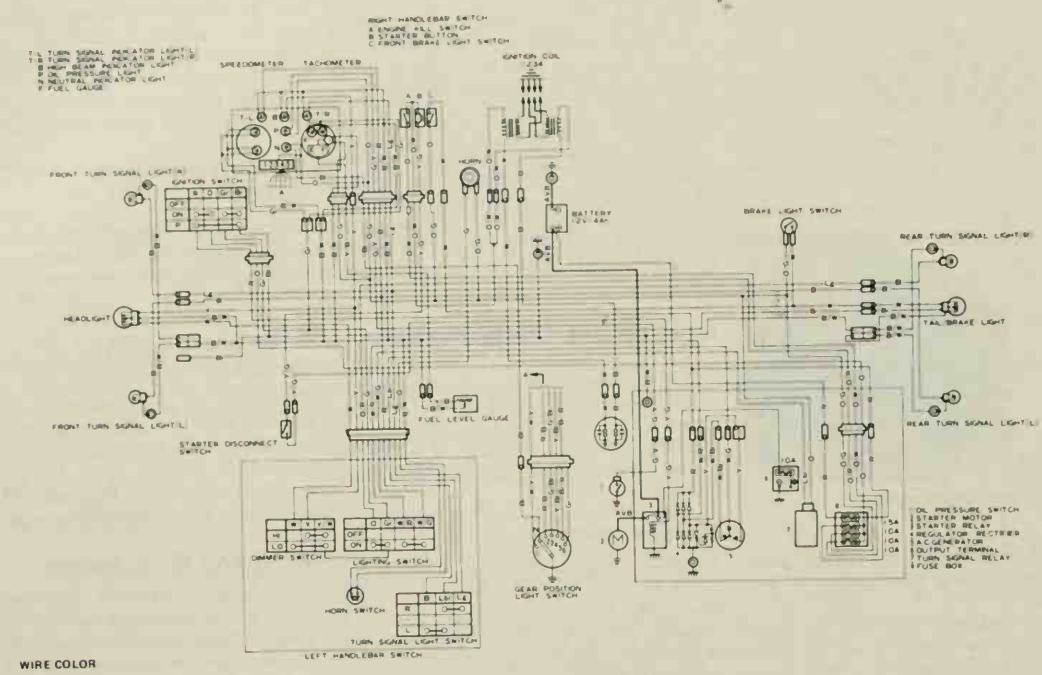
Disconnect the leads from the switch and check for continuity between them with the switch in both positions in turn.

For the right turn signal, there should be continuity between the light green and light blue leads.

For the left turn signal there should be continuity between the black and the light blue leads.

Kill Button/Starter Button

The kill button and starter button are combined into one three-pronged coupler inside the headlight shell.



When the kill button is in the "Run" position, there should be continuity between the orange and the orange/white wires.

When the starter switch is pushed, there should be continuity between the yellow/green and the orange/white wires.

Front Wheel Assembly

REMOVAL AND INSTALLATION (EXCEPT GS 750L)

1. Support the front wheel off the ground by placing a support beneath the engine.
2. Disconnect the speedometer cable from its drive box at the front wheel.

Axle nut (large arrow) and axle cap nuts

3. Remove the axle nut cotter pin. Loosen the axle nut. Unscrew and remove the axle cap nuts and take off the wheel.

CAUTION: *Do not operate the front brake lever with the wheel removed or the piston will be forced out of the caliper, necessitating brake work.*

4. Installation is the reverse of removal. Note that the axle caps are not meant to mate with the fork sliders. Instead, there must be a

small gap between them. Tighten the axle cap nuts so that this gap is equal at both the front and rear of the slider.

Tighten the axle cap nuts to 11–18 ft lbs.

Tighten the axle nut to 26–38 ft lbs.

Check front brake operation before riding the motorcycle.

REMOVAL AND INSTALLATION (GS 750L)

This model uses a front fork with an offset axle mount.

1. Support the front wheel off the ground.
2. Remove one of the two brake calipers by removing the caliper mounting bolts from the fork slider.
3. Remove the axle nut cotter pin, remove the axle nut, loosen the axle pinch bolt, and pull out the axle.

CAUTION: *Do not operate the front brake lever with the wheel removed or the pistons will be forced out of the calipers.*

4. Installation is the reverse of removal. Tighten the axle pinch bolt to 11–18 ft lbs. and the axle nut to 26–38 ft lbs.

Check brake operation before riding the motorcycle.

NOTE: *Be sure that the speedometer drive box is positioned so that the cable is not kinked or excessively bent before tightening the axle nut.*

WHEEL BEARINGS

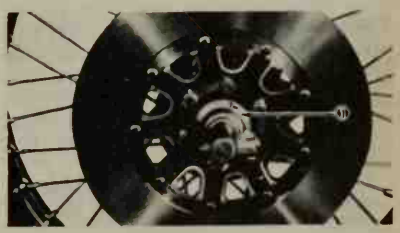
Removal

1. After removing the front wheel, unscrew and remove the axle nut and withdraw the axle. Remove the speedometer drive box, spacers, and covers from either side of the wheel.
2. Reach through the hub with a long drift and drive out one of the bearings. Remove the bearing spacer, and drive out the remaining bearing.

Inspection

1. Wash the wheel bearings thoroughly in a solvent to remove all of the old grease.
2. Inspect the general condition of the bearings. There should be no rust, pitting, or obvious signs of wear or damage on either balls or races.
3. Slowly rotate the bearing. Rotation should be smooth, noiseless, and free of binding or unevenness. If any of the above conditions exist, both bearings should be replaced.
4. Place each bearing on a flat surface and hold the inner race firmly in place. Attempt to move the outer race up and down. If any play is evident, the bearings should be replaced.
5. If equipment is available, a dial gauge can be used to check bearing run-out. Pass the axle through each bearing in turn and check the axial and diametrical run-out with the gauge. If axial run-out exceeds 0.1 mm (0.004 in.) or if diametrical run-out is greater than 0.05 mm (0.002 in.), the bearings should be replaced.

To check diameterical run-out, the dial indicator is placed directly on top of the outer race and the race moved up and down.



To check axial run-out, the gauge is positioned to bear against the side of the outer race and the race moved back and forth while holding the inner race in place.

Installation

Installation is the reverse of removal. Note the following points:

a. Pack the bearings with a good grade of bearing grease. Place a small amount in the hub as well.

b. Drive one bearing straight in until it is

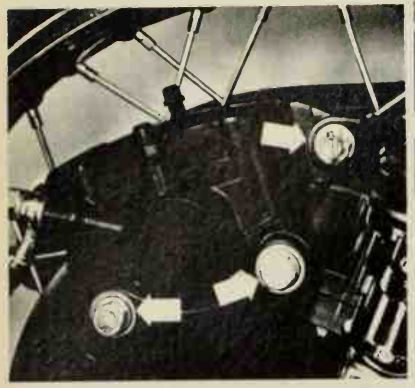
seated. Install the spacer, then the remaining bearing. Bearings are installed with their sealed side facing out.



c. Grease the speedometer drive box before installation. Install it so that the drive tabs engage the slots in the hub. Position the drive box so that the stamped "Up" arrow is pointing in the correct direction.

Rear Wheel Assembly

REMOVAL AND INSTALLATION (GS 750)

1. Remove the chain guard (2 bolts).
2. Remove the rear axle nut cotter pin. Loosen the axle nut.
3. Remove the two chain adjuster support bolts.
4. Remove the caliper anchor bolt. Remove the two caliper mounting bolts. Lift the caliper from its bracket and hang it out of the way. Be careful that the brake line is not twisted or otherwise subjected to stress.
5. Loosen the chain adjuster bolts and turn both adjusters down and out of the way so that the wheel can be taken off. Remove the chain adjuster supports.
6. Push the wheel forward as far as possible and disengage the chain from the rear sprocket.
7. Pull the wheel back and turn it to the side to remove it from the machine.
8. Installation is the reverse of removal. Note the following points:
   a. Install the wheel and the brake caliper. Tighten the chain adjuster support bolts to the proper torque (11–15 ft lbs), and the other nuts and bolts so that they are just hand-tight or a little more. Adjust the chain tension.
   b. Tighten the axle nut to 62–83 ft lbs.
   c. Spin the wheel while altering caliper position slightly so that there is no or little drag from the brake pads. With the caliper in this position, tighten the mounting bolts to 15–22 ft lbs.
   d. Tighten the caliper anchor nut to 15–22 ft lbs.

REMOVAL AND INSTALLATION (GS 850)

1. Park the bike on the centerstand on a firm, level surface.
2. Insert a phillips screwdriver into the right side of the centerstand.
3. Remove the upper shock absorber nuts and pull the shocks off the mounting lugs.
4. Use a 14 mm wrench or socket and ratchet on the rearmost caliper bolt to raise the swing arm slightly. As this is done, insert a bar through the right muffler support and swing arm hole.
5. Remove both shocks.
6. Disconnect the brake anchor from the caliper.
7. Remove the axle nut cotter pin and the axle nut. Pull out the axle while holding the caliper. Hang the caliper from the upper shock absorber mount.
8. Detach the wheel from the differential and remove it from the machine.
9. To remove the wheel from the fender well, it may be necessary to compress the front forks. Bleed pressure from the forks slowly. Turn the forks to the right and use the fork compressing tool.
10. Installation is the reverse of removal. Be sure that all components are properly torqued:

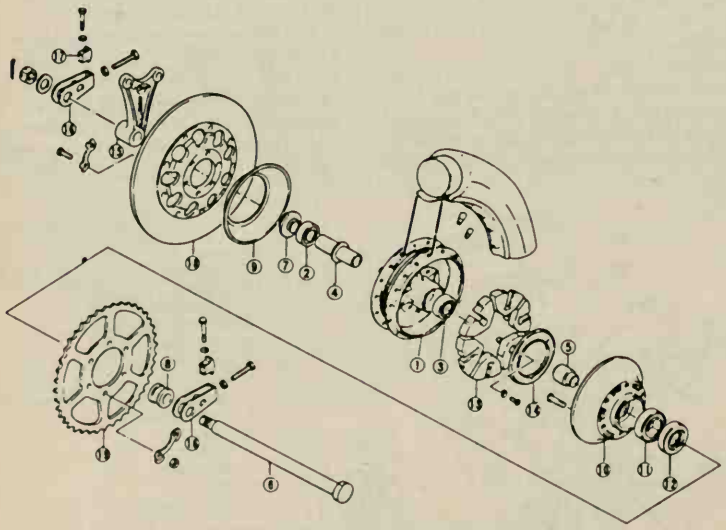
Axle nut: 62–83 ft lbs. (G/GL/GN)
36–58 ft lbs. (GT/GLT)
Brake anchor bolt: 15–22 ft lbs.
Shock nuts: 15–22 ft lbs.

WHEEL BEARINGS

Removal

1. Remove the axle nut and pull out the axle making careful note of the relative locations of the components such as chain adjuster plates, caliper bracket, and spacers which will come off.
2. Separate the sprocket hub from the wheel.
3. Reach through the hub with a long drift and drive out one of the bearings. Remove the spacer and drift out the remaining bearing.

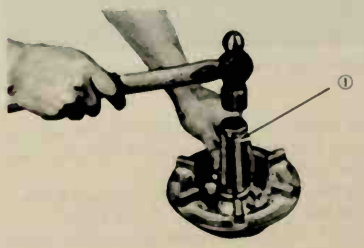
Inspection



Check bearing condition as outlined for the front wheel bearings, above.

Installation

Installation is the reverse of the removal procedure. Note the following points:
   a. Thoroughly pack each bearing with a good quality bearing grease. Put a small amount of grease in the hub as well.
   b. Drive the bearings straight in until they are seated. Install the bearings so that the sealed sides face outwards.



Sprocket Hub

1. The sprocket hub contains a bearing and an oil seal. The bearing can be removed by prying out the oil seal and driving the bearing out towards the sprocket side of the hub. Inspection is the same as for wheel bearings described above.
2. Installation is accomplished by driving the bearing straight into the hub (from the sprocket side) until it is seated. The bearing should be lubricated with bearing grease.

Rear wheel assembly

Removing the sprocket hub bearing

3. A new grease seal must always be used. Press it straight into the hub from the sprocket side. Grease the lips of the seal before installing the axle.

4. Check the shock absorber rubbers in the hub for damage and replace them if necessary.

Sprocket

1. Check the sprocket teeth for a hooked condition or other obvious signs of wear or damage. A worn sprocket should be replaced along with the chain and engine sprocket.

2. To remove the sprocket, bend down the securing nut lock tabs and remove the nuts. Installation is the reverse of removal.

FRONT BRAKE SERVICE (EXCEPT GS850GT/GLT)

Pad Replacement

1. Support the front wheel off the ground by placing a support beneath the engine. Remove the wheel.

2. Remove the screw which secures the fixed (inner) pad to the caliper and remove the pad.

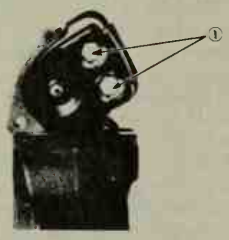
3. Move the caliper over as far as possible and take out the remaining pad.

4. Pads which are worn to the red limit line must be replaced.

5. Installation is the reverse of removal. The screw which secures the fixed pad should be secured with a non-permanent thread-locking compound.

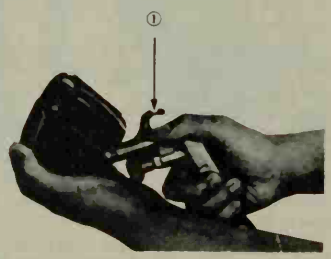
6. Before installing the moving (outer) pad, lightly smear its back and sides with the special silicone pad grease. The grease helps to keep pad operation smooth by repelling dirt and water as well as providing lubrication. Do not get any of the grease on the disc side of the pad.

7. Avoid heavy braking for at least fifty miles to allow the pads to seat properly.



Caliper

Leakage of brake fluid from around the caliper piston indicates a bad piston seal or damage to the piston or caliper bore. The cause should be investigated and remedied immediately. To remove, inspect, and rebuild the caliper assembly:



1. Remove the front wheel. Slightly loosen the two caliper shaft bolts.

Caliper mounting bolts

Caliper shaft bolts

Removing the piston with compressed air

2. Disconnect the brake line fitting at the caliper and catch the brake fluid which will drain off in a suitable container. Discard this brake fluid. Used brake fluid should never be reused. Pump the brake lever to flush out all the fluid.

3. Remove the fixed pad securing screw. Remove the fixed pad, then the moving pad.

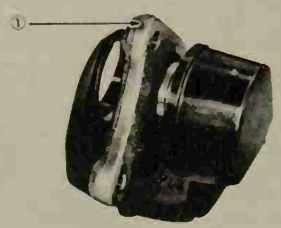
4. Remove the two caliper mounting bolts and separate the caliper from the fork slider.

5. Unscrew and remove the two caliper shaft bolts. Remove the caliper holder.

6. Remove the piston boot. Apply compressed air to the brake line drilling on the caliper and force out the piston.

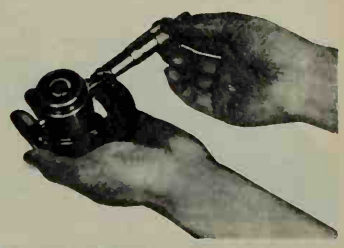
7. Remove the dust seal and piston seal.

8. Check the pads for wear. Replace the pads as a set if either is worn to the red limit line.



9. Measure the piston diameter and the inside diameter of the piston bore. Standard piston diameter is 42.82 mm (1.686 in.). The piston must be replaced if the measured diameter is less than 42.77 mm (1.684 in.). The standard bore diameter is 42.85 mm (1.687 in.). The caliper must be replaced if the bore measures more than 42.89 mm (1.689 in.).

10. Clean the piston and the seals and o-rings by washing them in clean brake fluid.



CAUTION: *Do not use any fluid other than clean, new brake fluid on the brake parts.*

11. The use of all new rubber parts is recommended.

12. Coat the piston seal with fresh brake fluid and install it in the caliper, being sure that it is properly seated.

Caliper holder (1)

Measuring piston diameter

Piston seal in place (1)

13. Put the caliper holder in place. Lightly coat the piston with fresh brake fluid and install it in the caliper.

14. Install the pads, smearing the back and sides of the piston pad with the special silicone pad grease.

15. Smear the caliper shaft bolts with the special shaft grease. Install the shaft bolts and tighten them gradually and evenly until the proper torque (18–25 ft lbs.) is reached.

16. When fitting the caliper to the fork slider, tighten the caliper mounting bolts to 18–29 ft lbs. Tighten the brake line bolt to 11–18 ft lbs.

17. Refill the master cylinder with new brake fluid and bleed the lines as outlined below.

Master Cylinder

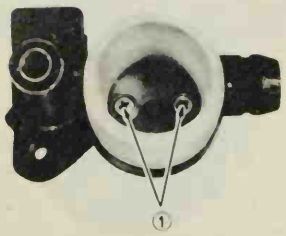
Brake fluid leakage around the brake lever and excessive lever travel (after bleeding the lines to make sure that there is no air trapped in the hydraulic system) are indications of master cylinder malfunction. The rebuilding procedure is as follows:

CAUTION: *Be very careful, when removing and replacing the master cylinder, in filling the reservoir. Brake fluid can damage paint and plastic, and extreme care should be exercised in its handling. Wipe up any spills immediately.*

1. Place a cloth underneath the connection to absorb any spilled fluid and disconnect the brake hose from the master cylinder.

2. Unscrew the clamp bolts and remove the master cylinder from the handlebar. Unscrew the reservoir cap, remove the diaphragm plate and diaphragm, and discard the brake fluid.

3. Remove the cotter pin and nut and take off the hand lever.



4. Remove the rubber boot. Using the special tool, remove the circlip from the master cylinder bore.

5. Using a soft wood drift or the like, push the piston assembly out of the bore from the line side. Be sure that this is done carefully to avoid scratching the bore.

6. Remove the two screws which hold the

Removing the master cylinder assembly circlip

Reservoir securing screws

Measuring the piston diameter

master cylinder reservoir and remove it and its o-ring.

7. Measure the diameter of the master cylinder piston and the piston bore. Specifications differ depending on whether the single or double-disc set-up is fitted.

For single-disc models, the standard piston diameter is 13.96 mm (0.550 in.), and the piston should be replaced if the diameter is less than 13.94 mm (0.549 in.). The standard bore diameter is 14.00 mm (0.551 in.), and the master cylinder should be replaced if the measured bore diameter is more than 14.05 mm (0.553 in.).

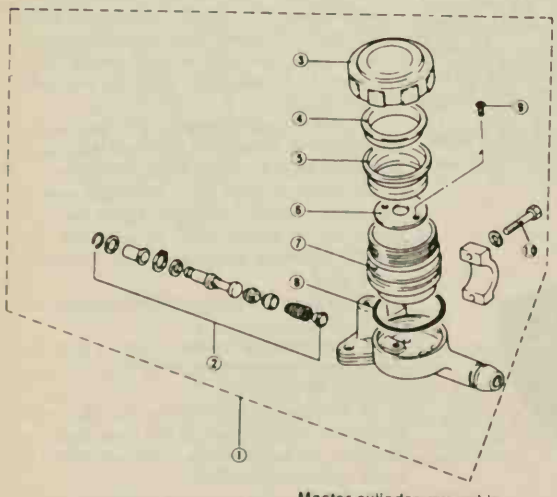
For double-disc models, the piston diameter is 15.80 mm (0.622 in.) and the bore diameter is 15.87 mm (0.625 in.).

8. If fluid leakage was noted around the bottom of the master cylinder reservoir, the fault probably lies with the reservoir o-ring which should be replaced.

9. Clean the piston assembly in new brake fluid only. The use of new rubber parts (boot, primary and secondary cups) is recommended.

10. Assembly is basically the reverse of disassembly. Lightly lubricate the master cylinder bore and the piston assembly with clean new brake fluid before inserting the piston assembly in the bore. The piston assembly should be inserted as a unit, not one piece at a time. Be sure that the check valve does not become cocked or unseats the spring as it is inserted.

11. The use of a new circlip is recommended. Be sure that the circlip is properly seated in its groove, with the sharp edge away from the spring.



12. When mounting the master cylinder on the handlebar, allow a clearance of about 2 mm (0.08 in.) between the master cylinder clamp and the twist grip.

13. When tightening the brake line bolt, arrange the line so that it is about 15° from vertical. Tighten the bolt to 11–18 ft lbs.

14. Refill the system with fresh brake fluid and bleed the line as outlined below.

Measuring brake disc thickness

Checking brake disc run-out

Disc Service

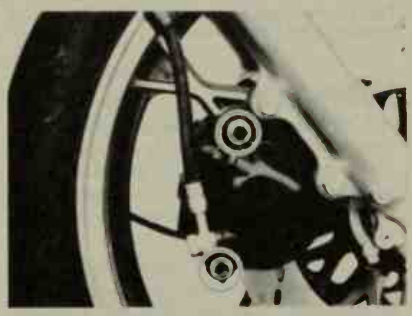
The brake disc normally requires no service of any kind. However, if the disc becomes scored for any reason, it should be replaced and a new set of pads should be installed. A badly scored disc will reduce the effectiveness of the brake and shorten pad life considerably. If the front brake lever oscillates or fluctuates

when the brake is applied at speed, the indication is that the brake disc is warped or bent. Check the run-out of the disc with a dial indicator and replace it if run-out exceeds 0.3 disc. Standard thickness is 6.7 mm (0.264 in.) for single front discs and 6.0 mm (0.236 in.) for double front disc, while the serviceable limits are 6.00 mm (0.236 in.) and 5.50 mm (0.220 in.) respectively. To replace the disc:

1. Remove the wheel.
2. Bend back the locktabs (if fitted), unscrew the bolts, and remove the disc from the hub.
3. Mount the new disc on the hub and tighten the bolts evenly to 11–18 ft lbs. using new loktabs (if fitted) or thread-locking compound to secure the bolts.
4. Examine the brake pads and replace them if they are close to the limit of wear or have worn in an unusual pattern.

Bleeding

The brake hydraulic system must be bled whenever any part of the system has been disconnected or removed for service. When refilling the master cylinder reservoir, use only brake fluid conforming to DOT 3 specifications. Any brand meeting this requirement is acceptable. The brake fluid container of all reputable brands will be plainly marked with the standards the fluid meets or exceeds.



NOTE: *If you have a double disc setup, bleed the side furthest from the master cylinder first, then bleed the other side. Pulling and tapping on the lines will help expel any air bubbles trapped in the system. If you find that you can't get the system bled properly and the master cylinder has been dry for awhile, the seals inside the cylinder may have become dried and cracked. In this case rebuild the master cylinder.*

1. Top up the reservoir with brake fluid and replace the cap to keep dirt and moisture out and the fluid in. Cover the gas tank with a thick cloth to avoid damage due to spilled brake fluid.
2. Attach one end of a small diameter rubber hose to the bleed valve on the caliper, and place the other end in a jar which contains several inches of clean, new brake fluid. Be sure that the end of the hose is submerged in this fluid. Arrange the hose so that it loops upward after leaving the bleed valve, and see that it has no kinks or sharp bends.
3. Pump the brake lever rapidly several times until some resistance is felt and, holding the lever against the resistance, open the bleed valve about one-half turn. When the lever bottoms, close the valve (do not overtighten) and then release the lever.
4. Repeat this operation until no more air is released out of the hose and the brake lever is firm in operation. Check the fluid level in the reservoir often to make sure that it doesn't go dry and draw more air into the system. Do not reuse fluid that has been pumped out of the system. Do not use fluid that has been stored for more than a few weeks after the seal on its container has been opened, as brake fluid will absorb moisture from the air and may corrode the master cylinder and caliper.
5. Refill the reservoir to the level mark when through (but do not overfill). Avoid overtightening the cap or fluid will weep around the cap edge.

FRONT BRAKE SERVICE (GS 850GT/GLT)

Pad Replacement

1. Remove the two caliper-to-axle bolts and take the caliper from the holder.
2. Remove the pads and shim.

Caliper axle bolts

3. Install the new pads. They must always be replaced as a set. Do not use pad grease on this brake system.
4. When refitting the caliper, push the piston in all the way to facilitate assembly.
5. Tighten the caliper axle bolts to 11–15 ft lbs.
6. Avoid heavy braking for about fifty miles after installing new pads to allow them to seat properly.

CAUTION: *Do not operate the brake lever while the caliper is removed or the piston will be ejected.*

Caliper

Leakage of brake fluid from around the caliper piston indicates a bad piston seal or damage to the piston or caliper bore. The cause should be investigated and remedied immediately. To remove, inspect, and rebuild the caliper:

1. Disconnect the brake line at the caliper and squeeze the lever repeatedly until all of the fluid is pumped out of the system. Discard this fluid.
2. Remove the two axle bolts which secure the caliper to the holder.
3. Remove the two bolts which secure the caliper holder to the fork slider.
4. Stuff a clean rag into the caliper and apply *low pressure* air to the brake line banjo hole to push out the piston.

CAUTION: *Do not use high pressure compressed air. Keep fingers out of the caliper.*

5. Remove the boot and piston seal from the caliper and discard them. New seals must be used.
6. Check the brake pads for wear. Replace them as a set if either is worn to the red limit line.
7. Check the surfaces of the caliper piston and the inner surfaces of the caliper bore for scoring, pitting, or rust. The components should be replaced unless these surfaces are in perfect condition.
8. Measure the diameter of the piston. It should be 38.098–38.148 mm (1.4999–1.5019 in.).
9. Measure the inside diameter of the caliper bore. Standard bore diameter is 38.180–38.256 mm (1.5031–1.5061 in.).
10. Clean the piston, interior bore, and caliper passages in clean brake fluid.

CAUTION: *Do not use any fluid other than clean, new brake fluid on the brake parts.*

11. The use of all new rubber parts is recommended.
12. Coat the piston seal with fresh brake fluid and install it in the caliper, being sure that it is properly seated.
13. Coat the inside of the caliper bore and the sides of the piston with brake fluid before installation.

The remainder of the procedure is the reverse of disassembly. Note the following points.

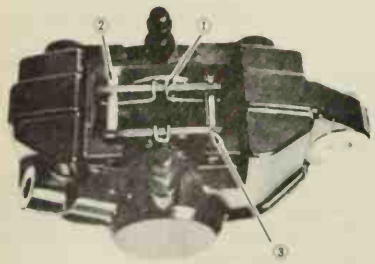
Grease the caliper axles and tighten axle bolts to 11–15 ft lbs.

Tighten the caliper bolts to 18–29 ft lbs.

Master Cylinder

Brake fluid leakage around the brake lever and excessive lever travel (after bleeding the lines to make sure that there is no air trapped in the system) are indications of master cylinder malfunction. The rebuilding procedure is as follows:

CAUTION: *Be very careful, when removing and replacing the master cylinder. Brake fluid can damage paint and plastic, and extreme care should be exercised in its handling. Wipe up any spills immediately.*



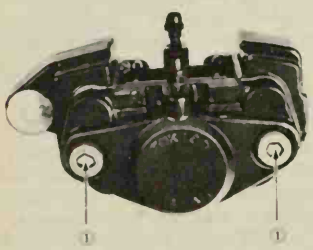
1. Place a cloth underneath the connection to absorb any spilled fluid and disconnect the hose from the master cylinder.
2. Remove the front brake light switch.
3. Remove the brake lever.
4. Unbolt the master cylinder clamp and remove the master cylinder from the handlebar.
5. Remove the reservoir cap and drain off the fluid.
6. Remove the reservoir and o-ring.
7. Pry out the piston dust seal boot.
8. Use a pair of snap-ring pliers, remove the circlip. Take out the piston assembly.
9. Master cylinder bore diameter is 15.870–15.913 mm (0.6248–0.6265 in.). Piston diameter is 15.827–15.854 mm (0.6231–0.6242 in.).
10. Assembly is the reverse of disassembly. Clean all metal parts in clean brake fluid. All rubber parts should be replaced. Lubricate the bore and piston assembly with brake fluid before assembly.

When installing the reservoir assembly on the handlebar, tighten the uppermost mounting bolt first. Adjust the brake light switch.

REAR BRAKE SERVICE

Pad Replacement

1. Remove the pad inspection cap.
2. Remove the stopper pin from the end of each pad pin.
3. Remove the two pad pins and take out the pads.
4. If the same pads are to be reused, mark their relative locations (inner or outer) so that they can be reinstalled in their original locations.
5. Pads must be replaced when they are worn to the red limit line.
6. When fitting the pads, install the outside pad first. Be sure that the springs are not left out. Install the pad pins and the stopper pins.

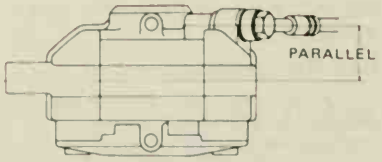


Rear disc brake pad springs (1), pins (2) and pads (3)

NOTE: *Although it is possible to install new pads with the caliper installed, Suzuki warns that the piston boots may be displaced when this is done. If this happens, it will be necessary to remove the caliper and then install the pads.*

Caliper

1. Disconnect the brake line at the caliper.
2. Unbolt the caliper anchor.
3. Remove the two caliper mounting bolts and take off the caliper.
4. Remove the pad inspection cap. Remove the stopper pins, the pad pins, springs, and pads.
5. Unscrew and remove the two caliper allen bolts, and separate the caliper halves.
6. Remove the piston boots. Apply compressed air to the fluid passage of each caliper half to force the pistons out of their bores.



Caliper allen bolts (1)

7. Measure the diameter of each piston and each piston bore and compare the measurements.

Standard piston diameter is 38.15 mm (1.502 in.) and the pistons should be replaced if the diameter is less than 38.18 mm (1.501 in.).

Standard bore diameter is 38.18 mm (1.503 in.) and the caliper should be replaced if either bore measures more than 38.19 mm (1.504 in.).

8. Clean all parts in clean, fresh brake fluid. It is recommended that the piston boots, piston seals, and fluid passage seal be replaced with new parts.
9. When assembling the caliper, be sure that the fluid passage seal is in place. Tighten the allen bolts to 18–25 ft lbs.
10. Tighten the caliper mounting bolts to 18–30 ft lbs., and the brake anchor nut to 15–22 ft lbs.
11. When fitting the fluid line, arrange it so that the line runs parallel to the centerline of the caliper. Tighten the fitting bolt to 11–18 ft lbs.

Tighten the banjo bolt so that the brake line is parallel to the caliper body

Master Cylinder

NOTE: *Late models have a modified rear master cylinder in which the reservoir itself is separated from the piston/cylinder housing and is connected by a hose. Other than this, procedures and specifications are the same.*

1. Remove the right-side rider's footpeg.
2. Remove the brake pedal and remove the cotter pin from the brake rod. Push out the clevis pin.
3. Disconnect the brake line at the master cylinder.
4. Remove the two master cylinder mounting bolts and take off the master cylinder.
5. Remove the master cylinder cap, diaphragm plate and diaphragm and pour out the brake fluid.
6. Remove the pushrod boot. Remove the pushrod circlip using the special tool or a suitable substitute. Push the piston assembly out from the opposite side.
7. Remove the two screws securing the master cylinder reservoir and remove it and the o-ring.
8. Measure the diameter of the piston and that of the cylinder bore.

Standard piston diameter is 13.96 mm (0.550 in.), and the piston should be replaced if the measured diameter is less than 13.94 mm (0.549 in.).

Standard bore diameter is 14.00 mm (0.551 in.), and the master cylinder should be replaced if the measured diameter exceeds 14.05 mm (0.553 in.).

9. Clean all parts in clean, fresh brake fluid. The use of new cups and o-ring is recommended.
10. Assembly is the reverse of disassembly. Lightly lubricate the piston assembly with clean, fresh brake fluid. Insert the assembly into the master cylinder as a unit. Be sure that the check valve and spring are properly seated and that the primary cup does not become cocked inside the bore.
11. When fitting the circlip, be sure that it is properly seated.
12. After mounting the master cylinder to the frame (bolt torque: 11–15 ft lbs.) and connecting the fluid line (bolt torque: 11–18 ft lbs.), refill the master cylinder with clean, fresh brake fluid and bleed the system.

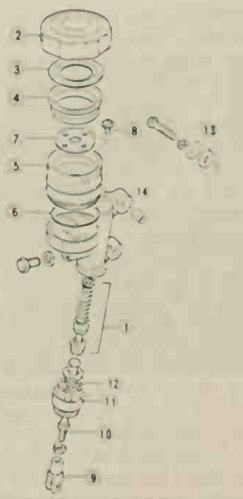
Bleeding

Bleeding the rear brake system is carried out in the same manner as for the front brake outlined above. The rear caliper has two bleed nipples, unlike the front which has only one. Bleed the wheel side nipple first, then the outer nipple.

FRONT FORKS (GS 750)

Removal



1. Support the front wheel off the ground. Remove the front wheel and fender.
2. Remove the caliper(s) from the fork slider.

CAUTION: *Do not allow the caliper(s) to hang by the brake hose. Tie them out of the way with string or wire.*

3. Remove the fork filler cap at the top of each fork leg. Loosen the upper triple clamp pinch bolts to facilitate filler cap removal.

NOTE: *It may be necessary to remove the handlebars to do so, but the controls may be left connected, and the bars gently laid to one side when the mounting bolts are removed.*

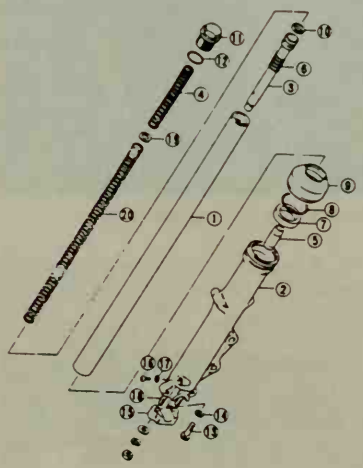
5. Grasp each fork leg, in turn, and remove it from the triple clamps by pulling downward. If this is difficult, install the filler cap(s), threading them in several turns, then strike them sharply with a plastic mallet or the like to drive the fork leg down and out of the triple clamps.

Removing a fork leg

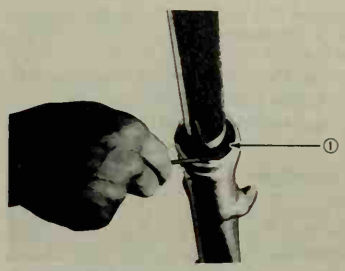
Disassembly



1. Having removed the fork filler caps, turn the forks upside down and drain off the oil. Remove the fork springs.
2. Pry the dust seal up off the slider. Pry out the oil seal circlip.
3. Remove the bolt at the bottom of the fork slider and separate the fork components.

Inspection

1. Inspect the fork tubes for bends such as might have been incurred in an accident. Replacement is recommended rather than attempting to straighten bent fork tubes.
2. Check that the surface of the tube on which the slider components move is smooth and free of rust or scoring. Minor rusting should be removed with fine emery cloth.



On fork tubes, the chrome plating must be in perfect condition. If it is peeled or damaged, the fork tube must be replaced if oil leaks occur.

3. Check the spring condition. Make sure the spring heights are equal.
4. Check that all damper components are clean.
5. Replace the fork filler cap o-rings if they are not in good condition.
6. Clean all metal parts thoroughly in a solvent and lubricate them lightly with fork oil before assembly.
7. New fork slider oil seals should always be used once the forks have been disassembled. Pry out the old seals with a small screwdriver or the like, taking care to protect the top edge of the slider which you are using as a fulcrum. Drive the new seal straight in, being sure it is not cocked or otherwise damaged as it is driven in. The old seal can be used to drive in new seals. Drive the new seal in just far enough to allow the circlip to be installed. Oil the lips of the seal thoroughly before assembly.

Installation

1. Install the fork leg in the triple clamps until the top edge of the fork leg is just flush with the top surface of the upper triple clamp.
2. Tighten the upper triple clamp pinch bolts to 15–22 ft lbs., and the lower ones to 11–18 ft lbs. Tighten the fork filler caps securely.
3. The remainder of the installation procedure is the reverse of removal.

FRONT FORKS (GS 850)

Removal

1. Remove the brake caliper(s) from the forks.

CAUTION: *Do not allow the caliper(s) to hang by the brake hose. Tie them out of the way with string or wire.*

2. Support the front wheel well off the ground by placing a jack or the like beneath the engine. Remove the front wheel and front fender.
3. After removing the valve cap at the top of each fork, slowly bleed the forks of air.
4. Loosen the upper triple clamp pinch bolt. Loosen the fork cap bolt. Loosen the lower triple clamp pinch bolts. Grasp each fork leg, in turn, and remove it from the triple clamps by pulling downwards.

Disassembly

1. Remove the fork cap and pull out the spring.
2. Drain off the fork oil, pumping the slider to remove it all.
3. Remove the dust seal.
4. Remove the allen bolt at the bottom of the fork slider. If the damper assembly inside turns with the allen bolt, it may be possible to break it loose by temporarily installing the

spring and fork cap and attempting to loosen the bolt. Otherwise, the special tool will have to be used.

5. Remove the fork slider from the fork tube. Remove the damper assembly.

6. Remove the fork slider oil seal snap-ring, washer, and oil seal.

Inspection

1. Inspect the fork tubes for bends such as might have been incurred in an accident. Replacement is recommended rather than attempting to straighten bent fork tubes.

2. Check that the surface of the tube on which the slider components move is smooth and free of rust or scoring. Minor rusting should be removed with fine emery cloth.

On fork tubes, the chrome plating must be in perfect condition. If it is peeled or damaged, the fork tube must be replaced if leaks occur.

3. Check the spring condition. Make sure that the spring heights are equal.

Springs should be replaced if either is under 416 mm (16.4 in.).

4. Check that all damper components are clean.

5. Replace the fork cap o-rings if they are not in good condition.

6. Clean all metal parts thoroughly in a solvent and lubricate them lightly with fork oil before assembly.

7. New fork slider oil seals should always be used once the forks have been disassembled. Pry out the old seals with a small screwdriver or the like, taking care to protect the top edge of the slider which you are using as a fulcrum. New seals should be installed after the fork tube has been installed in the slider to avoid having it cocked to one side.

Assembly

1. Assembly is the reverse of disassembly. Tighten the slider allen bolt to 15–19 ft lbs.

2. When installing the fork springs, note that they are inserted so that the close spring coils are located at the upper end of the fork tube.

3. Add 251 cc (8.5 oz) of SAE 10W/20 oil to each fork leg.

4. Install the fork legs as outlined below.

Installation

1. Install each fork leg so that the top lip of the tube is flush with the upper surface of the triple clamp.

2. Tighten the upper triple clamp pinch bolt to 15–22 ft lbs.

3. Tighten the lower triple clamp pinch bolts to 11–18 ft lbs.

4. Air pressure of the front forks must be matched with rear suspension settings. See "Suspension Adjustments," below.

STEERING STEM ASSEMBLY (GS 750)

Bearing Adjustment

1. The steering stem bearings are uncaged balls. They are adjusted by means of a ring nut beneath the upper triple clamp.

2. To check bearing adjustment, support the front wheel off the ground. Grasp the tip of the front fender and place your other hand beneath the lower triple clamp at the frame lug.

3. Attempt to move the fork by pulling up on the tip of the fender. If play or movement can be felt at the lower triple clamp, the bearings are adjusted too loosely or are worn. An alternate method is to grasp the fork sliders and attempt to move them back and forth in line with the motorcycle. No play should be noted.

4. Turn the forks slowly from lock-to-lock. Movemement should be smooth, silent, and effortless. If any binding or uneven movement is felt, the balls and races are either too tightly adjusted or they are worn. If the steering feels uniformly stiff, the bearings are too tightly adjusted. If any noise is noted, the bearings are damaged or some are missing.

5. With the front wheel off the ground, release the front forks from a few degrees off the centered position. The fork should fall freely to either side of their own weight. If they will not, the bearings are too tightly adjusted, the steering stem is bent, the races are extremely worn, or some of the bearings are missing.

6. To adjust the bearings, remove the upper triple clamp. The bearings are adjusted by means of the adjuster nut under the upper triple clamp.

7. Tighten or loosen the adjuster nut a little at a time until the steering stem adjustment conforms to that outlined above.

Steering head bearing adjuster nut

8. If proper adjustment is not possible, the bearings and races will probably need to be replaced.

Disassembly

1. Support the front wheel off the ground. Disconnect the clutch cable at the hand lever. Disconnect the tach and speedometer cables at the instruments.

2. Remove the headlight. Disconnect the wiring inside the headlight shell and remove the shell.

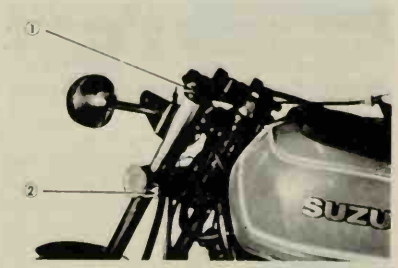
3. Remove the master cylinder from the handlebar. Remove the brake line guide which is secured to the upper triple clamp.

4. Remove the bolts securing the brake line joint to the lower triple clamp. Unbolt the caliper(s) from the fork slider(s) and remove the entire brake system.

5. Disconnect the instrument wiring, remove the two mounting bolts and remove the instruments.

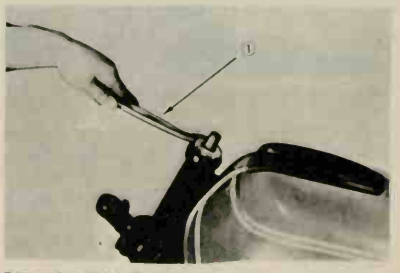
6. Remove the handlebar bolts and take off the handlebars.

7. Remove the front wheel.



8. Loosen the upper and lower triple clamp pinch bolts and remove the fork assembly.

9. Loosen the rear pinch bolt on the upper triple clamp. Remove the steering stem bolt. Remove the upper triple clamp.



10. Loosen the steering stem adjuster nut with a pin wrench, then hold the steering stem up while unscrewing the adjuster nut the rest of the way off. Remove the steering stem top cone race.

Brake line joint

Upper and lower triple clamp pinch bolts (1 & 2)

Removing the adjusting nut

11. Carefully lower the steering stem out from the bottom. Some of the ball bearings from the lower race will probably fall out at this time so be prepared for this.

12. Remove the bottom cone race from the steering stem if it is to be replaced. This will have to be pried off with a chisel, therefore only remove it if necessary.

13. The bearing races in the frame lug are a press-fit and should not be removed unless re-

placement is necessary. If replacement is necessary, the old races can be removed by reaching through the frame lug with a suitable

Driving out a steering stem bearing

punch and tapping the race evenly around its circumference to remove it from the inside of the frame lug. Be sure that the race does not become cocked in its seat upon removal.

New races are installed with a suitably sized bearing driver, i.e., one which will drive the race squarely into its seat. Be certain that the race goes straight in.

These races can also be installed using a block of hard wood of sufficient size to cover the race in place of a bearing driver.

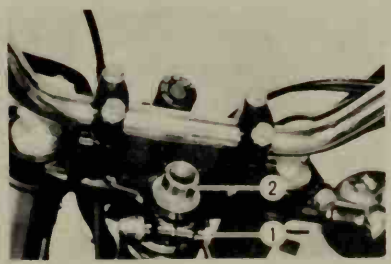
Inspection

1. Wash the ball bearings in a suitable solvent.
2. Clean all of the old grease from the bearing race surfaces, steering stem, and frame lug.
3. Inspect the bearing race surfaces. They must be clean and smooth and free of any cracks, scoring, rust, or indentations. Run your finger around each of the bearing races. Note any roughness or ripples on the race surface. If any imperfections are noted, both sets of races and all of the balls must be replaced.
4. Check the balls themselves for rust, pitting, scoring, or flat spots. If the balls are found to be defective in any way, the balls and both sets of races must be replaced.

NOTE: *Balls and races must always be replaced in a set because worn races will destroy new balls and worn balls will destroy new races.*

5. Check the steering stem for cracks or a bent condition; this is especially important if the bike has been involved in a spill.

Installation



1. Install the lower cone race on the steering stem. Use a good grade of bearing grease to coat the bottom cone race and the upper race in the frame lug.
2. Embed 18 balls into the grease of the top frame lug and 18 balls into the grease of the lower cone race.
3. When the balls are in place, slip the steering stem through the frame lug and hold it in place while refitting the top cone race and threading on the adjuster nut.
4. Tighten the adjuster nut all the way by hand, rotating the steering stem to work the grease into the balls.
5. Tighten the adjuster nut until the steering stem turns freely, but has no play.
6. Install the fork tubes, headlight assembly, and upper triple clamp, and steering stem bolt. Check that the stem moves freely to the steering lock of its own weight when released from 5°–10° off center; if not check for:
   a. Steering bearings too tight;
   b. Bent steering stem;
   c. Worn races or balls.
7. Install the front fender, front wheel, and handlebars.
8. When installing the handlebars, adjust them so that the punch mark aligns with the mating face of the handlebar holder. Install the handlebar clamps, and tighten the front bolt first. Tighten the bolts to 9–15 ft lbs.
9. When connecting the headlight's wiring, note that the turn signal lead wires are both black and the wiring harness leads are black for the left-side turn signal and light green for the right-side signal.

STEERING STEM ASSEMBLY (GS 850)

The GS 850 has tapered roller steering stem bearings in place of the uncaged balls used on the 750. The behavior of the front fork/stem assembly relative to bearing adjustment is as outlined under "Bearing Adjustment" for the GS 750, above- Steps 2–5, although the causes for bearing trouble given there are not necessarily applicable. Bearing adjustment is somewhat more complicated, and is given as part of the "Assembly" procedure, below.

Disassembly

1. Remove the gas tank.
2. Remove the headlight bulb and reflector assembly, disconnect the wiring inside, and remove the headlight shell.
3. Disconnect the tach and speedo cables from the instruments.
4. Remove the handlebar cover. Remove the meter assembly.
5. Remove the connection coupler at the end of the lead wire.
6. Loosen the rear pinch bolt of the upper triple clamp and loosen the steering stem lock nut.
7. Remove the front forks. Refer to the section above.
8. Remove the headlight shell brackets. Unbolt the brake line junction beneath the lower triple clamp. Unbolt the master cylinder. Unbolt the handlebars from the upper triple clamp.

Upper triple clamp pinch bolt (1) and locknut (2)

9. Remove the upper triple clamp steering stem lock nut. Remove the upper triple clamp.
10. Loosen the bearing adjusting nut holding the steering stem assembly from below while the nut is taken off. Lower the assembly out of the frame lug.

Inspection

Wipe off any old grease and check the bearings and races for the usual signs of damage.

The lower bearing must be removed from the steering stem with a puller.

The races in the frame lug are to be driven out in the usual manner, and installed by pressing into place.

Assembly

1. Thoroughly grease the bearings and races with a good brand of bearing grease.
2. Insert the steering stem into the frame lug, hold it in place, and install the upper bearing and dust seal.
3. Screw on the adjusting nut. Now adjust the bearings to the proper play in the following manner.
4. Tighten the adjusting nut just enough so that there is no excessive play in the steering stem assembly, but it still turns freely.
5. Tighten the steering stem adjusting nut to 29–36 ft lbs.

Turn the steering stem back and forth several times to seat the bearings.

6. Loosen the adjusting nut, then tighten it just enough so that there is no play in the assembly.
7. Install the upper triple clamp. Tighten the steering stem locknut to 15–22 ft lbs. Tighten the pinch bolt behind it to 11–18 ft lbs.
8. Loosen the adjusting nut slightly. Torque the steering stem nut to 26–38 ft lbs.
9. Check operation of the steering stem. It must turn freely, of course. If too tight, or too loose, first loosen the steering stem nut, then turn the adjusting nut until operation is correct.
10. The remainder of the procedure is the reverse of removal. Tighten the handlebar bolts to 9–15 ft lbs.

REAR SHOCKS

Rear shocks are sealed units which cannot be disassembled or repaired. If a shock is damaged due to accident, leaks oil, or if damping is unsatisfactory, it must be replaced.

Shock absorbers should always be replaced in sets to ensure uniform damping.

Removal and Installation

1. The shock absorbers can be removed after their upper and lower fasteners are taken off.
2. To remove the spring, first set the cam ring on the softest position. Compress the

Install the bars so that the punch mark aligns with the clamp surface

spring by hand or with the aid of levers and remove the spring retainers.

3. Check damper operation by pushing the damper rod in as far as possible and then pulling it out. It should be more difficult to pull the damper rod out if the shock damper is functioning properly. Furthermore, both shocks should behave in exactly the same manner.

4. When refitting the shock absorbers, tighten the lower bolt to 15–22 ft lbs, and the top nut to the same torque.

Spring/Damper Settings

Rear shock absorbers on the GS 850 have a four-position damper adjustment as well as the usual five-position spring adjustment.

The spring and damper adjustment must be matched according to the following chart:

Spring setting	*Damper setting*
1	1 or 2
2	2 or 3
3	3 or 4
4	3 or 4
5	4

CAUTION: *Any spring/damper combinations other than those given may cause unsafe riding conditions. Be sure that both units are set to the same adjustments. Nos. "1." refer to the softest spring and damper setting.*

Be sure to check and, if necessary, adjust the front forks as well. See below.

SUSPENSION ADJUSTMENTS

The unique nature of the GS 850 suspension system requires that rear shock spring/damper settings be matched to front fork air pressure for maximum handling.

CAUTION: *Suspension components must be matched according to the following chart or unsafe riding conditions may arise.*

Rear spring setting	*Rear damper setting*	*Front fork air pressure (psi)*
1	1	8.5–17
1	2	11–13
2	2	11–13
2	3	11–13
3	3	14–16
3	4	14–16
4	3	14–16
4	4	14–16
5	4	17

WARNING: *Only the suspension settings indicated by this chart are considered safe. Do not adjust only the front or rear suspension to the neglect of the other.*

SWING ARM (GS 750)

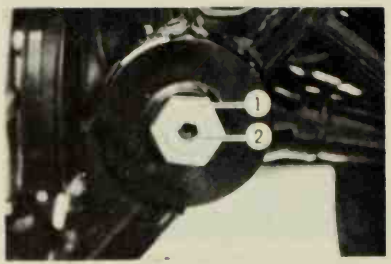
Inspection

Grasp the rear tire and attempt to move it from side to side. There should be no movement allowable. If there is, assuming that the rear wheel bearings are in good condition, it indicates bad swing arm bearings which should be replaced.

Removal and Installation

1. Remove the rear wheel as outlined above.
2. Remove the right-side rider's footpeg. Remove the rear brake lever.
3. Disconnect the brake rod at the clevis. Remove the two master cylinder mounting bolts.
4. Remove the rear shock absorbers.
5. Remove the swing arm pivot shaft nut

Removing the swing arm pivot



and take out the pivot shaft. Remove the swing arm from the frame.

6. Remove the brake anchor and the caliper and master cylinder from the swing arm.
7. Using special tool no. 00941-44510, remove the needle bearings from the swing arm. Once removed, the bearings must be replaced.
8. Assembly is the reverse of disassembly. Install the bearings with the aid of the special tool. Be sure to lubricate the bearings thoroughly before installation. Grease the spacers and dust caps as well.
9. When installing the pivot shaft, tighten its nut to 36–58 ft lbs.

SWING ARM (GS 850)

Removal

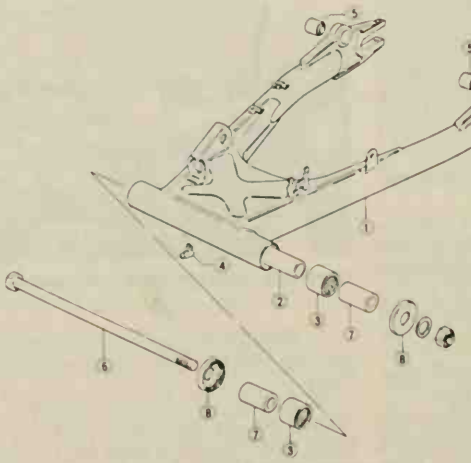
1. Remove the rear wheel.
2. Remove the brake caliper.
3. Remove the rear drive box.
4. Move the rubber boot aside. Disconnect and remove the brake light switch.
5. Remove the cotter pin from the master cylinder pushrod.

Swing arm nut (1) and pivot bolt (2)

6. Remove the swing arm nuts on each side and loosen the pivot shafts. Remove the swing arm.

Be cautious that the bearings do not fall out of either side of the pivot tube.

Inspection



Tapered roller swing arm bearings are fitted and, after washing them in a clean solvent to remove the old grease, the rollers, races, and cages should be inspected in the usual manner. Look for scored, pitted, rusted, or otherwise damaged rollers or races. Damage would be unlikely unless the bearings were not lubricated.

Installation

1. Grease the bearings with a good grade of bearing grease.
2. Tighten the pivot shafts to 2.5–3.0 ft lbs.

CAUTION: *The gaps between the frame and swing arm should be even on both sides.*

3. Tighten the locknuts to 80–94 ft lbs.

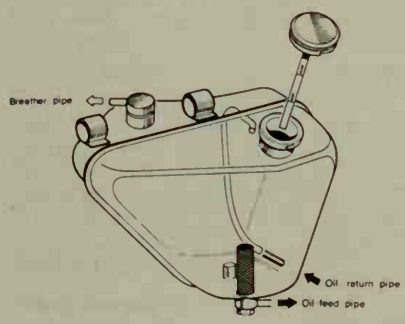
MAINTENANCE

NOTE: *Common maintenance procedures are explained in detail in "General Information."*



LUBRICATION

Engine

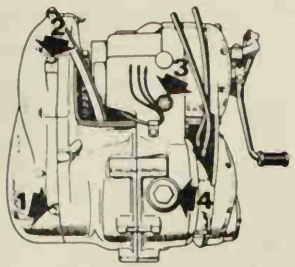
NOTE: *Always change oil when the engine is at operating temperature.*

TR25W

1. Remove the right side-panel.
2. Using a suitable container and funnel to catch the oil, remove the oil tank filter located in the lower right corner of the tank. Clean the filter in solvent.
3. Allow the tank to drain for about five minutes, then lean the machine toward the right side to make sure that all the oil has been removed.
4. Remove the four attaching nuts and the oil sump filter located at the bottom of the crankcase. Also, disconnect the supply and scavenge lines at the crankcase union nut.
5. Wash the sump filter in solvent, then allow it to air dry or blow it dry with compressed air.
6. Reinstall the sump filter and gasket, connect the supply and scavenge lines, and reinstall the oil tank filter.
7. Add the recommended oil to the tank until it reaches the correct level mark on the dipstick. Do not overfill it, as excessive venting will result.
8. Let the engine run for several minutes, then recheck the oil level and top up if necessary.

250 oil tank

500 AND 650



1. Remove the sump drain plug and filter.
2. Thoroughly clean the filter in solvent.
3. Allow the oil to drain for approximately five minutes, then reinstall the filter (with gasket) and the sump drain plug.
4. Remove the oil tank filler cap.
5. Position a container under the oil tank, then remove the tank drain plug or disconnect the oil feed line.
6. Remove the oil tank filter and clean it thoroughly in solvent.
7. If possible, clean the oil tank with

flushing oil. If it is not available, use kerosine, but make sure all traces are removed before filling the tank with oil.

8. Fill the tank with the recommended lubricant. The correct level is 1½ in. below the filler cap. Do not exceed this level, as excessive venting will result.

9. Allow the engine to run for several minutes, and recheck the oil level, topping it up if necessary.

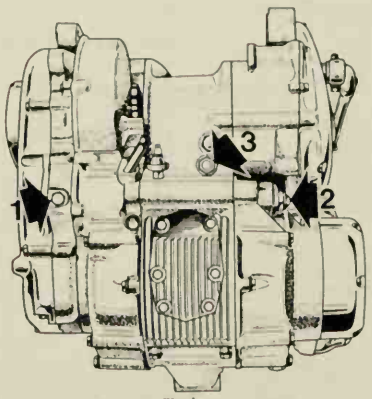
TR7V, T140V

Note that the oil for these models is carried in the frame backbone. A filter is also fitted at the bottom of the frame oil reservoir.

1. When the engine is warm, remove the hex-head sump drain plug from beneath the engine. This plug houses the sump filter as well.

2. Allow the oil to drain from the sump for at least ten minutes. Clean the sump plug filter in a suitable solvent, check the condition of the gasket, then replace the filter and the drain plug.

3. Remove the oil reservoir filler cap. Remove the drain plug from the center of the base plate at the very bottom of the frame oil reservoir. Allow to drain for at least ten minutes.



4. Remove the four nuts which secure the cover plate at the bottom of the reservoir, and remove the plate from the studs. Noting the location of the two gaskets (one above the filter base flange, and the other below), clean the filter in a suitable solvent.

5. Flushing the reservoir with kerosene is recommended.

6. The filter gaskets should be replaced. Refit the filter, cover plate, cover plate nuts, and drain plug. Fill the reservoir with the correct amount and recommended grade of oil. Check the oil level after the engine has been run for several miles.

T150, T150V

1. When the engine is warm, remove the six nuts and lockwashers which secure the crankcase sump filter plate to the bottom of the crankcase. Carefully remove the plate. Allow the oil to drain for about ten minutes.

Trident

1. Primary chaincase drain plug
2. Oil filter housing cap
3. Gearbox drain and level plug

2. Clean the sump filter in a solvent. The gaskets on either side of the filter should be replaced upon reassembly. Replace the filter, noting that the pocketed end is towards the rear of the engine. Tighten the nuts gradually and evenly.

3. Remove the oil tank filler cap, and the right side-panel. Drain the oil from the oil tank, then remove the tank oil filter, and wash it in a solvent.

4. Flushing out the oil tank with kerosine is recommended.

5. Remove the cartridge-type main feed oil filter. This is located beneath the large cap nut just below the forward end of the gearbox outer cover. Note that the filter is pulled out with a pair of needle-nosed pliers. There is a spring immediately beneath the cap nut, and an O-ring on the end of the filter. The filter should be replaced every time the oil is changed.

6. When replacing the filter, be sure that the O-ring and the fiber washer are in good condition.

CAUTION: *When the filter is refitted, be sure that the hole in the filter faces inward.*

Refill the oil tank with the correct quantity and recommended grade of oil. Check the level with the dipstick after the engine has run for several miles.

Gearbox

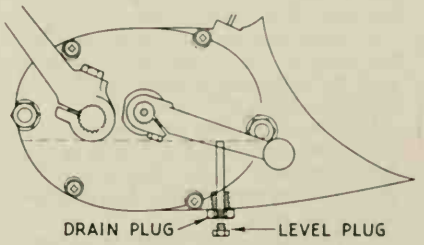
All gearbox components, including the shifter and kick-start mechanisms, are lubricated by oil splash. The oil should be changed at 500 miles in new or reconditioned engines, and at every recommended service interval thereafter.

NOTE: *Drain oil when it is warm.*

TR25W

1. Remove the nylon filler plug and the dipstick from the top of the gearbox.

2. Remove the plug on the bottom of the gearbox and drain the oil.



3. After draining, reinstall the plug, making sure that the sealing O-ring is in good condition.

4. Fill the gearbox with the recommended lubricant to the line marked on the dipstick.

OTHER MODELS

1. Remove the transmission drain plug located at the bottom of the gearbox.

2. After letting the oil drain for about ten minutes, reinstall the drain plug, but without the level plug that normally screws into it.

Gearbox drain and level plug

3. Remove the gearbox oil filler plug on the case cover and add fresh oil until it flows out the level plug hole.

4. Reinstall the level plug.

Primary Chaincase

Like the gearbox, the primary chaincase is lubricated by oil bath. On all models, the primary oil supply is contained within the case, where a collection chamber and a feed pipe provide direct lubrication to the primary chain and sprockets.

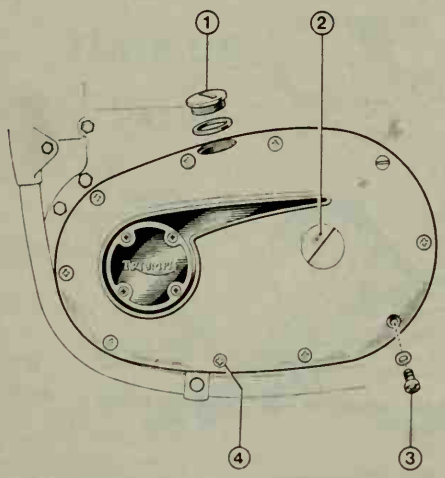
TR25W

1. On early machines, two of the chaincase securing screws serve as drain and level plugs. On later bikes, a vertical drain plug is provided at the bottom of the case and the forwardmost of the lower chaincase securing screws serves as a level plug.

2. Remove the chain inspection cap on top of the chaincase.

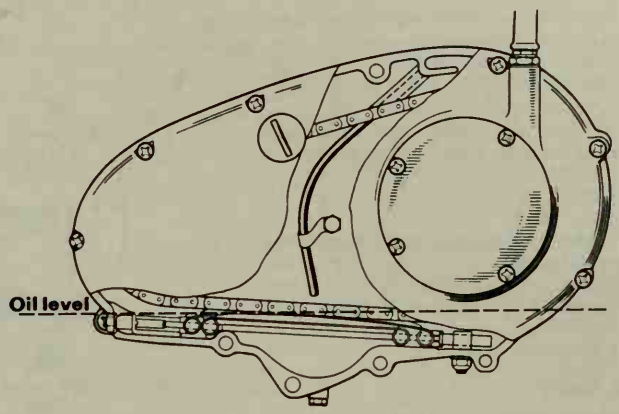
3. Remove the drain plug or screw and level screw.

4. Let the oil drain for about ten minutes, then reinstall the drain plug or screw.



5. Pour the specified amount of the recommended lubricant into the chaincase through the chain inspection cap until it flows out the level screw hole.

6. Reinstall the level screw and chain inspection cap.



NOTE: *Oil containing molybdenum disulphide or graphite, or oil additives, must not be used in the primary chaincase.*

TWINS

On models after about 1971, the primary chaincase oil is automatically supplied by oil forced through the drive side crankshaft bearing. The level is main-

Early 250 chaincase filler (1), clutch adjustment cap (2), level (3) and drain (4) screws

Chaincase oil level (Trident)

tained by drillings which allow excess oil to re-enter the crankcase.

1. Remove the primary chaincase drain plug. This is also the chain adjuster cover plug. On some 500 models it may be necessary to remove the footpeg, striking it after the bolt is loosened to remove it from its taper.

2. Allow the oil to drain for about 10 minutes. Reinstall the drain plug. On older models, remove the level plug.

3. Remove the filler plug at the top of the case. On the older models, add the correct grade oil until it begins to seep from the level plug hole. Refit the level plug and filler plug.

On the more recent machines, add only about ¼ pint of motor oil. The level will come up to the proper amount as the machine is ridden. Check with the level plug.

T150, T150V

1. The primary chaincase is lubricated by oil forced through the crankshaft bearing as outlined for late-model Twins.

2. After removing the drain plug and allowing several minutes for the oil to drain off, refit the drain plug. Add no more than ½ pint of motor oil. The level will rise as the machine is ridden, and will be maintained at the proper level by drillings in the crankcase.

Front Forks

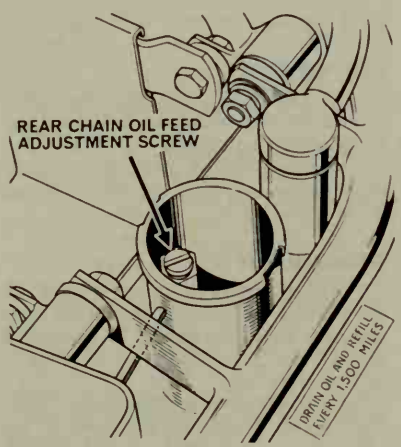
1. Drain each fork leg separately.

2. Remove the drain bolt at the bottom of the fork slider. Hold the front brake and pump the forks several times to expel all the oil.

3. Refit the drain plug. Remove the filler cap at the top of the fork leg.

NOTE: *On machines with resiliently-mounted handlebars, the handlebars may have to be removed to gain access to the filler caps.*

4. Add the correct amount and type of oil, refit the cap; repeat the procedure with the remaining fork leg.



Final Drive Chain

TR25W

Lubrication of the final drive chain is totally dependent on the oil level in the primary chaincase. As the primary chain spins, it throws off the oil fed by the primary case collection chamber. This oil is collected by a small well at the back of the primary case and is then drip-fed to the chain.

500, 650, 750-3

The drive chain on these models is lubricated by means of an overflow tube from the neck of the oil tank. The flow is adjusted by means of a screw with a tapered tip threaded into the oil junction block in the neck of the tank. The screw is accessible after removing the tank filler cap. To increase oil flow to the chain, turn the screw counterclockwise. To decrease flow, turn the screw clockwise.

Chain oiler adjustment screw location (500, 650, and Trident)

750 TWINS

The chain should be lubricated by hand at intervals, depending on conditions. No automatic oiler is fitted.

Grease Nipples

Both the front and rear drum brake cams, and the swinging arm pivot are fitted with grease nipples. The brake cams should be given only one stroke of a hand grease gun; the swinging arm pivot should be greased until the lubricant spurts out the pivot O-rings.

Brake Pedal Spindle

The brake pedal spindle is located on the left, rear, engine mounting plate. Since the operating shaft is exposed to the air, it should be coated with grease to prevent dirt penetration and corrosion.

1. Back off the rear brake rod adjustment until there is plenty of play.

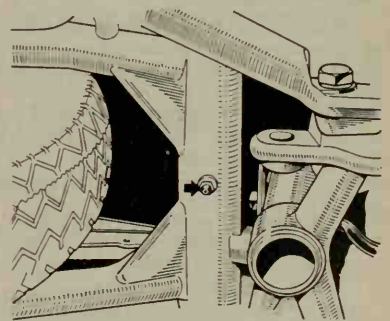
2. Remove the pedal retaining nut and pedal.

3. Clean up the operating shaft and bore of the pedal with fine emery cloth.

4. Apply the recommended grease to the shaft and reinstall the pedal. Make sure you don't forget the spring and washer that accompany the retaining nut.

Wheel and Steering Head Bearings

1. These bearings should be packed with a good grade of bearing grease every 12,000 miles.



2. Refer to "Chassis" for removal and installation procedures.

SERVICE CHECKS AND ADJUSTMENTS

Clutch

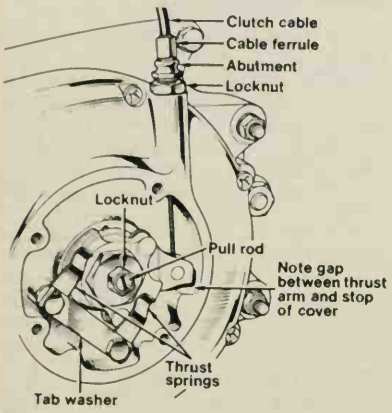
TR25W, TWINS

1. Run down the clutch cable adjuster(s) until there is plenty of freeplay in the clutch hand lever.

Swing arm grease nipple (650)

2. Remove the clutch adjustment cap on the primary chaincase.

3. Loosen the adjustment nut. Turn the adjusting screw out a few turns, then turn it in until resistance is felt.



4. At this point, back the adjusting screw off the following number of turns:
TR25W: 1
500: ½
650, 750: 1

5. Tighten the adjusting screw locknut while holding the screw in position. Use the cable adjusters to allow ¼ in. (3 mm) of freeplay between the clutch hand lever and the lever holder before the clutch begins to disengage.

T150, T150V

1. Remove the four screws which secure the clutch inspection plate to the primary chaincase.

2. Run down the clutch cable adjusters both at the handlebar and the chaincase cover so that there is plenty of slack in the clutch cable.

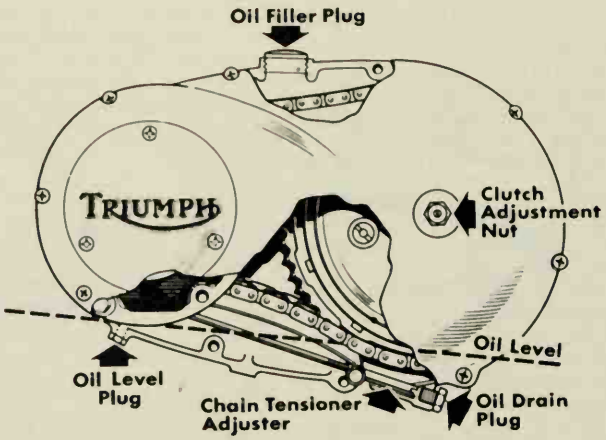
Trident clutch adjustment

3. Loosen the small locknut on the end of the clutch pull-rod. Then turn the large nut until the proper setting is obtained. This will be not less than 0.005 in. measured between the rear face of the large adjuster nut and the ball bearing in the actuating plate. Be sure that the clutch pull-rod does not turn, and retighten the small locknut. Recheck the setting.

4. Adjust the cable so that there is just a very small amount of freeplay at the handlebar lever.

Primary Chain Adjustment

ALL MODELS



An occasional adjustment is necessary to compensate for chain wear. Excess chain slack is taken up by tightening the tensioner bolt.

1. Remove the primary chaincase filler or inspection cap. Place a pan beneath the chaincase and remove the tensioner plug. On most models, the chaincase oil will drain off.

2. Chain slack should be as follows:
TR25W: ¼ in. (6 mm)
Trident: ½ in. (12 mm)
Others models: ⅜ in. (9.5 mm)

This is total up-and-down movement. If adjustment is necessary, use a screwdriver to turn the tensioner bolt until tension is correct.

3. After refitting the tensioner plug, refer to "Primary Chaincase" lubrication to fill and check oil level.

500 and 650 chaincase

Final Drive Chain

1. Chain slack should be ¾ in. (19 mm) total up-and-down movement measured in the middle of the chain run with the machine on its wheels. With the bike on the center stand, the slack should be 1¾ in. (43 mm).

Measure at the chain's tightest point.

2. If adjustment is necessary, loosen the axle nut and the brake anchor. Move the wheel by turning the adjustment bolts by equal amounts.

3. Apply the rear brake and tighten the axle nuts.

Brakes

DISC BRAKES

1. The brakes are self-adjusting. Maintain the fluid level at ¼ in. below the top of the master cylinder.

2. Brake pads should be replaced when either of them reaches a lining thickness of 1/16 in. (1.6 mm).

FRONT DRUM

1. On single-leading shoe brakes, use the adjuster at the wheel so that the hand lever can be moved about 1 in. (measured at the tip of the lever) before the shoes contact the drum.

2. On twin-leading shoe brakes, hand lever travel should be the same (1 in., measured at the tip of the lever) and is effected by using the adjuster at the hand lever.

REAR DRUM

1. If a change in pedal position is desired, do this before adjusting the brake.

2. Use the adjuster at the end of the brake rod so there is ½ in. (12 mm) of pedal movement before the shoes contact the drum. The measurement should be made with the weight of a rider on the motorcycle.

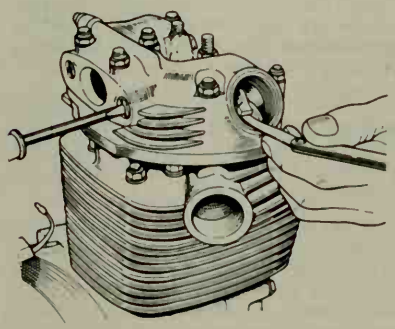
TUNE-UP

NOTE: *Common tune-up procedures are explained in detail in "General Information."*



VALVE ADJUSTMENT

NOTE: *Valves are adjusted when the engine is cold.*

TR25W

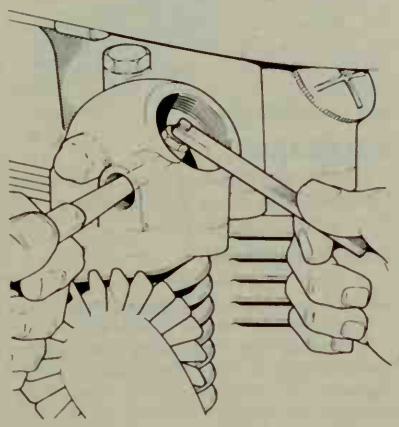
1. Remove the spark plug, rocker inspection caps, and rocker spindle plate. Also, put the transmission in gear so that the engine can be easily rotated by turning the rear wheel.

2. Rotate the engine in the normal running direction until the intake valve has just completely closed.

Valve adjustment (250)

NOTE: *This point can be accurately located by feeling the pushrod. When the valve is completely closed, the pushrod will be free to rotate.*

3. The engine is now correctly positioned for checking the exhaust valve clearance. Slide the appropriate feeler gauge between the valve stem and the tappet, and check for a snug slip-fit.



4. If an adjustment is necessary, loosen the rocker spindle locknuts opposite the spindle cover plate. Turn the slotted exhaust valve spindle in a clockwise direction until the rocker arm just touches the valve stem, then turn it back again until the correct clearance is obtained. Tighten up the locknut and recheck the adjustment.

5. Rotate the engine forward again until the exhaust valve is just about to open. This is the correct position for checking the intake valve tappet clearance.

6. Check the clearance with the proper feeler gauge and, if necessary, readjust it to meet specifications. The procedure for adjusting the intake valve clearance is the same as that outlined for the exhaust valve except that the rocker spindle should first be turned counterclockwise, rather than clockwise.

Twins

1. Remove the spark plugs and rocker box inspection caps.

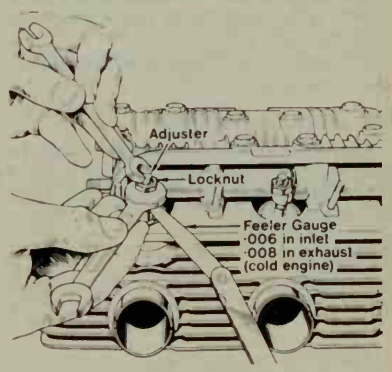
Valve adjustment (500)

2. On 500cc models, remove the large plugs on the side of each rocker box. The feeler gauge is inserted through these holes.

3. Slowly turn the engine over until the left exhaust valve is fully open. Now check the clearance of the right exhaust valve.

4. Insert the proper thickness feeler gauge between the valve stem and rocker arm. The feeler gauge should be a snug slip-fit if the clearance is correct.

5. If adjustment is necessary, loosen the adjuster locknut and turn the adjuster to effect the proper clearance. Hold the adjuster in place and tighten the nut. Recheck the clearance.



6. Turn the engine over so that the right exhaust valve is fully open, then check the adjustment of the left exhaust valve. Repeat this procedure with the intake valves.

NOTE: *If, in an emergency situation, feeler gauges of the proper thickness are not available, clearances can be set approximately by turning the adjuster in until it is finger-tight, then backing it out ¼ turn per 0.010 in. until the given clearance is obtained. Check this setting with a feeler gauge as soon as possible.*

T150, T150V

1. Remove the spark plugs and rocker box inspection caps.

2. Beginning with the intake cam, rotate the engine until two valves are opened by the same amount (approximately 1/16 in.). At this point, with one of the valves just opening and the other just closing, the third valve is correctly positioned for adjustment.

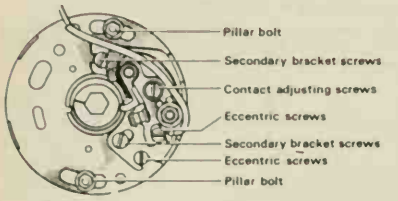
Valve adjustment (Trident)

3. Insert the appropriate feeler gauge and, if necessary, loosen the adjuster locknut and turn the adjuster until a snug slip-fit is obtained. Tighten the locknut and recheck the clearance.

4. Continue rotating the engine until the conditions outlined in step 2 are met for another intake valve. Repeat the procedure on the remaining intake and exhaust valves.

5. Install the spark plugs and rocker box inspection caps.

CONTACT BREAKER POINTS



NOTE: *When installing new points, the contact surfaces should be wiped with a solvent to remove any preservative coating.*

TR25W

The contact breaker point assembly is located behind the circular cover on the right side of the engine.

REMOVAL

1. Remove the breaker point cover.
2. Remove the securing nut, nylon

Breaker points (250)

sleeve, and contact breaker lead.

3. Remove the contact adjusting screw, then lift the unit out.

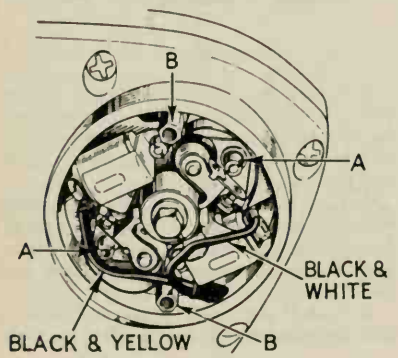
INSTALLATION

Installation is a reversal of the removal procedure. Do not forget to install the fiber washer that fits between the moving point spring and the fixed point backing plate.

GAP ADJUSTMENT

1. Put the transmission in gear and rotate the engine by turning the rear wheel until the nylon heel of the contact breaker is aligned with the scribed mark on the breaker cam.

2. Loosen the contact adjusting screw and turn the eccentric screw until a snug slip-fit is obtained with the appropriate feeler gauge.



3. Tighten the adjusting screw and recheck the gap.

500 (Before H57083)

The point assembly is located behind a circular cover plate on the right side of the engine, and is driven off the right exhaust camshaft.

REMOVAL

1. Remove the points cover and gasket.

Breaker points (500 before H57083): sleeve nuts (A) and pillar bolts (B)

2. Remove the two sleeve nuts ("A" in the illustration), withdraw the points and condenser, and carefully disconnect the primary wire.

INSTALLATION

Installation is the reverse of removal. Add a drop of motor oil to the point pivots before refitting.

GAP ADJUSTMENT

1. Remove the spark plugs.

2. Rotate the engine until the nylon heel of one set of points aligns with the mark scribed on the breaker cam.

3. Insert the appropriate feeler gauge and, if necessary, loosen sleeve nuts "A" (see illustration) and shift the breaker point plate until a snug slip-fit is achieved.

4. Repeat the above for the other set of points.

5. Check to make sure the breaker plate is correctly positioned. The set of points with the black/yellow lead should be situated toward the rear. Also make certain that the pillar bolts are in the center of their adjustment slots.

500 (H57083 and Later), 650, 750 Twin

The points are beneath a cover plate on the right, front side of the engine.

REMOVAL

1. Remove the cover plate.

2. Remove the primary wire terminal nut, and disconnect the wire, noting any insulators and their positions.

3. Remove the contact locking screw and remove the points.

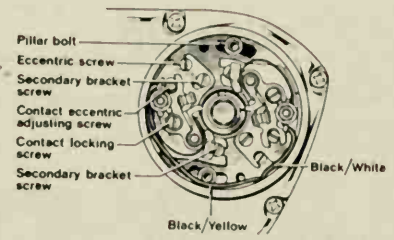
INSTALLATION

Installation is the reverse of removal. Lubricate the pivot with a drop of oil. Note wire connections.

GAP ADJUSTMENT

1. Turn the engine over until the scribed mark on the breaker cam aligns with the nylon heel of one of the points.

2. Check the gap with the proper feeler gauge. It should be a snug slip-fit if correct. If adjustment is necessary, loosen the contact locking screw, and turn the contact eccentric adjusting screw until the gap is correct. Tighten the locking screw and recheck gap.



3. Repeat the procedure with the other set of points.

T150, T150V

The procedure for removal, installation, and gapping is the same as outlined for 650 and 750 Twins, above, except that three sets of points must be gapped. Note wire color codes by referring to the accompanying illustration.

IGNITION TIMING

NOTE: *Points should be cleaned and gapped before setting ignition timing.*

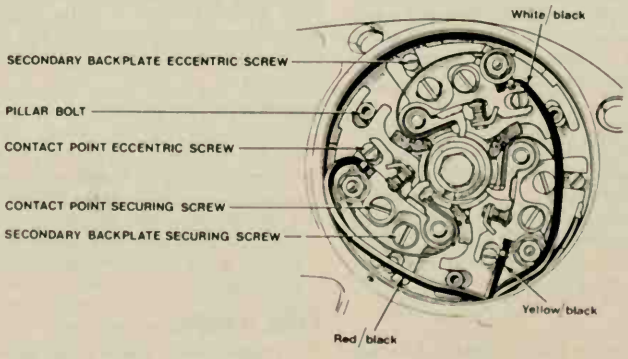
Breaker points (500 after H57082 and other twins)

TR25W

INITIAL PROCEDURE

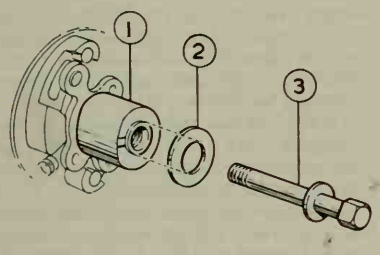
Before actually setting static timing, the piston must be located at the specified number of degrees before top dead center and the automatic spark advance mechanism must be locked in the fully advanced position.

1. Remove the small inspection cover at the front of the primary chaincase.



2. As can be seen through the aperture, a timing mark is scribed on the face of the alternator rotor and a pointer is mounted at the bottom of inspection hole.

3. Rotate the engine until it is on its compression stroke (i.e., both valves closed), then align the rotor mark and pointer. The piston is now located 37° before top dead center.



4. An alternate method of locating the piston, only possible on later machines, is by using Triumph special plunger and body (no. 61-2915 and 61-D572). Locate the piston on its compression stroke, then rotate the engine gently backward while applying slight pressure to the plunger. The plunger will drop into position, locking the piston at 37° before top dead center.

5. Now that the piston is correctly located, the automatic advance unit must be locked in the fully advanced position. This is necessary because, due to manufacturing tolerances, slight variation in spark timing will occur at one end of the advance curve or the other. In general, it is preferred that this variation does not affect high speed performance; therefore the mechanism should be set at the fully advanced position so that any fluctuations will occur only at idle speeds.

6. Carefully remove the cam central bolt and fit an extra washer on the bolt.

Breaker points (Trident)

Locking the breaker cam (1) with an oversized washer (2) and central bolt (3)

This washer should have a hole just large enough to clear the cam inner bearing (see illustration).

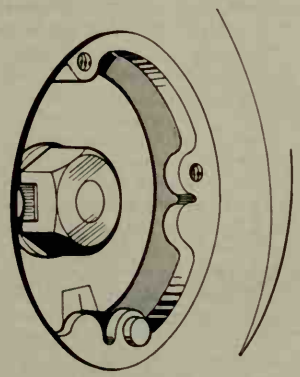
7. Reinstall the bolt, but before tightening it, rotate the cam counterclockwise until the advance weights are fully extended. Hold the weights in this position and tighten the central bolt.

8. After setting the final ignition timing, don't forget to remove the extra washer on the central bolt.

STATIC TIMING

1. With the piston correctly located and the advance mechanism locked in the full advance position, the ignition timing can now be set.

2. Hook up the test or continuity light: one lead to ground, the other to the primary wire terminal or points spring.



3. Loosen the two secondary bracket screws, and turn the eccentric screw in either direction until the points just open. Tighten the bracket screws.

4. If the points will not open using this method, set the eccentric screw in the middle of its adjustment range. Loosen the two pillar bolts which secure the large points plate, and rotate the entire plate until the points open. Make any necessary fine adjustments with the eccentric screw.

DYNAMIC TIMING

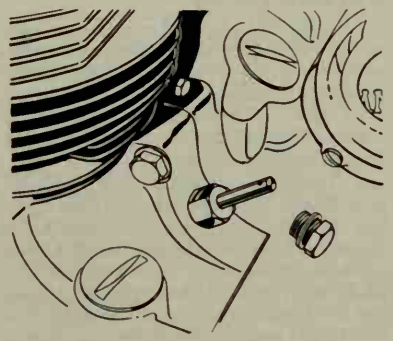
1. Remove the inspection cover at the front of the primary chaincase.

2. Hook up the strobe light. At engines speeds above 3,000 rpm, the mark on the alternator rotor should align with the fitted pointer.

Rotor and stator marks (250)

3. Make any ignition timing adjustments as described in Steps 3-4 under "Static Timing."

500 (Before H57083)



INITIAL PROCEDURE

Before setting ignition timing, the piston must first be positioned at top dead center.

1. Remove the spark plugs and rocker box inspection caps.

2. Put the transmission in gear so that the engine can be rotated by turning the rear wheel.

3. Locate the piston at top dead center, using a dial indicator, Triumph timing plunger and body no. D571/2, or, if necessary, a stick positioned in the spark plug hole. The right cylinder must be on the compression stroke.

Timing plunger is position (500)

STATIC TIMING

1. Remove the automatic advance unit and check the degree range stamped on the back. Make a note for future reference and reinstall the unit. A special extractor must be used to remove the unit.

2. Double the auto-advance range and subtract it from the fully advanced degree figure (38°). This is the correct static setting for the engine. Example:

AUTO-ADVANCE
DEGREE RANGE = 12°
FULLY ADVANCED
2 × 12° = 24°
38° − 24° = STATIC
TIMING

3. If a stick is used to locate top dead center, convert the degree figure into inches or millimeters by using the chart, then scribe a corresponding mark on the stick.

500 Twin Crankshaft Degree Conversion Chart

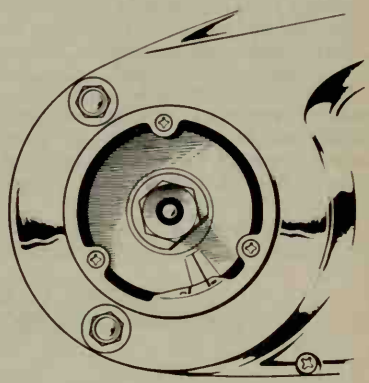
18	0.080	2.03
19	0.090	2.29
20	0.100	2.54
21	0.110	2.79

4. Fit a degree wheel to the auto advance unit and fasten a pointer to a convenient case cover screw.

5. If a dial indicator or timing plunger was used to locate top dead center, position the degree wheel and/or pointer to read TDC. Then remove the timing plunger (the dial indicator can remain) and carefully rotate the engine until it is at 38° before top dead center (right cylinder on the compression stroke), as indicated by the degree wheel and pointer.

6. Connect a timing light to the right cylinder points (black/yellow primary wire). Rotate the engine backward to a point below the static timing position. slowly approach the prescribed setting and, if necessary, adjust the breaker plate so that the points are just opening when the setting is reached.



Adjust the timing by rotating the breaker plate after loosening the pillar bolts "B."

7. Rotate the engine forward 360° and repeat the procedure on the second set of points, noting that the main breaker plate must not be disturbed.

NOTE: *To fine-tune the ignition timing, it is permissible to vary the breaker point gap slightly so that both cylinders are timed exactly the same. To advance the spark, open the points approximately 0.001 in. per crankshaft rotation degree.*

DYNAMIC TIMING

After locating top dead center and installing a timing disc as previously described, connect the strobe light on the right cylinder points. If a 6 or 12-volt external power supply is needed, *do not* use the motorcycle battery. AC current pulses in the bike's low tension wiring can trigger the strobe light and lead to incorrect readings.

Rotor and stator timing marks with Adaptor D2014 (500)

Aim the strobe light at the timing disc and rev the engine until the auto advance mechanism is actuated (2,000 rpm). The pointer and 38° BTDC on the disc should be exactly in line. If they are not, loosen the contact breaker-plate pillar bolts and make the necessary adjustment. Repeat the procedure for the other cylinder. Remember that the main breaker plate must not be disturbed after setting the right cylinder.

500 (H57083 and Later)

INITIAL PROCEDURE

These models are fitted with alternator rotor marks and timing plunger stops at TDC and 38° BTDC for each cylinder.

First make sure the auto advance unit is correctly positioned on the camshaft locating peg. Lock the auto advance in the full advance position using a suitably sized washer which will bear on the breaker cam when the bolt is tightened (see illustration). Remove the plugs and rocker box covers.

STATIC TIMING

1. Remove the plug behind and between the cylinders. Turn the engine over slowly in the normal direction of rotation until the right cylinder is on the compression stroke, and close to TDC.

2. Install timing plunger and body Nos. D653/D654 and rotate the engine slowly applying slight pressure to the plunger until it drops into the crankshaft hole. The engine should now be at TDC and the right cylinder should be on the compression stroke. Check that there is clearance at both valves. If not, turn the crankshaft 360° to locate the right cylinder on its compression stroke.

3. Lift out the plunger, and rotate the engine backwards. When the plunger drops for the second time, the piston is at the firing point of 38° BTDC.

4. If no timing plunger is available, the piston can be positioned at the firing point by removing the inspection cap from the front of the primary chaincase. After establishing the right piston at TDC on its compression stroke, turn the engine backwards until the rotor and stator marks align. This will be the full advance firing point.

NOTE: *Later machines have the stator pointer built in, but some earlier models require the use of adaptor No D2014 which has two marks, "B" and "C." Use the line marked "C."*

5. When the piston is positioned as outlined, a timing or test light should indicate that the right cylinder's points have just opened. The points for the right cylinder have the black/yellow primary wire.

6. If adjustment is necessary, loosen the two pillar bolts, and rotate the entire point plate until the points just open. Tighten the bolts.

7. Turn the engine 360°, engage the plunger or line up the rotor and stator marks to position the piston at 38° BTDC, and check that the left cylinder (black/white primary wire) just open. If they do not, loosen the two secondary bracket screws, and turn the eccentric screw until timing is corrected. Tighten the bracket screws.

NOTE: *If timing has been lost completely, as after rebuilding the engine, it is advisable to set the points plate and the eccentric screws at about the middle of their adjustment range before resetting the timing.*

DYNAMIC TIMING

1. A strobe light can be used by means of the rotor and stator timing marks beneath the plate at the forward end of the primary chaincase.

NOTE: *If the strobe light requires a battery power source, do not use the motorcycle battery.*

2. The marks should align above 2,000 rpm. Check the right cylinder (black/yellow primary wire) first, and adjust the timing, if necessary, by moving the point plate as explained in Step 6, above. Repeat the test with the left cylinder, changing the timing by moving the left cylinder points only as explained in Step 7, above.

650, 750 Twin

1. The procedures are the same as for 500 (H57803 and later) since the points are the same type. Note the following:

2. The plunger and body to be used are D2195/D572.

3. If the machine does not have a stator pointer, use D2014. If dynamic timing is being carried out with this pointer, use line "B."

T150, T150V

The Trident is equipped with one set of points for each cylinder. The firing order is one-three-two. The right (no. one) cylinder point lead is white/black; the center (no. two) red/black, and the left (no. three) yellow/black.

STATIC TIMING

NOTE: *Early model Tridents have three timing marks scribed onto the rotor, 120° apart, each one for a different cylinder. Late models have two sets of timing marks which are distinguished by "A" or "B."*

When timing late engines before Serial No. PG 01603, use the "A" timing marks. For engines after PG 01603, line up the "B" timing marks.

1. Remove the spark plugs and rocker box inspection caps. Put the transmission in gear so that the engine can be rotated by turning the rear wheel.

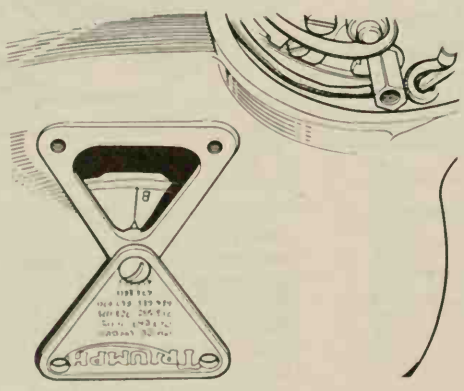
2. Locate approximate top dead center by rotating the engine until no. 1 piston is at the top of its compression stroke (i.e., both valves closed with clearance at the tappets).

3. Install Triumph timing plunger and body no. D1858, then slowly rotate the engine backward until the plunger locks the crankshaft at 38° BTDC.

4. If the automatic advance unit is not installed, assemble it loosely with an extra washer on the central bolt to lock the cam in the fully advanced position. If it is installed, remove the central bolt and add the extra washer. The washer should have a hole just a little larger than the cam bearing.

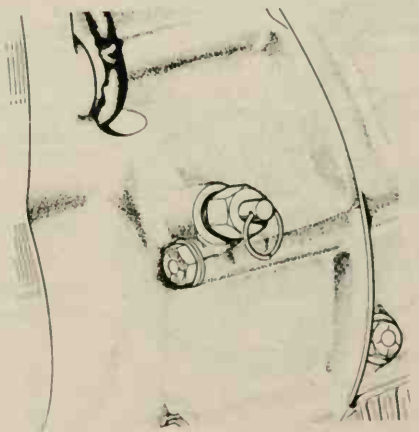
5. When the auto-advance unit is fully advanced, the no. 1 cylinder points should just be opening. If this is not the case, loosen the secondary breaker plate screws and shift the plate until the points begin to open.

6. Remove the timing plunger and locate the no. 3 cylinder at TDC on the compression stroke. Rotate the engine backwards until the plunger indicates that the piston is at 38° BTDC. Repeat the procedure outlined above on the no. 3 cylinder points, then again on no. 2 cylinder points.



7. Remove the extra washer on the central bolt.

DYNAMIC TIMING



1. Remove the two top screws of the Triumph patent plate on the primary chaincase. Just loosen the bottom screw, as it will serve as a pointer.

2. Remove the ignition inspection plate located at the front of the primary chaincase.

3. Connect the strobe light to the right cylinder as instructed by the strobe man-

Trident timing marks (from Engine No. PG01603)

Timing plunger installed (Trident)

ufacturer. If the unit requires an external power source, *do not* use the motorcycle battery. AC pulses in the machine's low tension wiring can trigger the strobe light and lead to incorrect readings.

4. At engine speeds above 2,000 rpm, one of the three marks on the alternator rotor (exposed by the Triumph patent plate) should line up directly with t bottom plate screw. If adjustment is necessary, loosen the no. 1 point set secondary bracket and shift the plate until the marks are aligned. Tighten the plate securing screws.

5. Repeat the above procedure on no. 2 cylinder (center), then no. 3 cylinder (left).

6. Reinstall the patent and inspection plates.

CARBURETOR ADJUSTMENTS

Idle Speed and Mixture

NOTE: *Make these adjustments when the engine is at operating temperature.*

SINGLE-CARBURETOR

1. Make sure there is some freeplay in the throttle cable so the slide will close fully.

2. Turn the pilot air screw in until it is lightly seated, then back it out 2½ turns. Start the engine. Adjust the idle speed (throttle stop) screw so that the engine idles at about 750 rpm.

3. Make any fine adjustments by turning the pilot air screw in either direction so that an even idle is obtained. It should not be necessary to vary this screw more than ½ turn from the standard setting. If it is, there may be something wrong with the carburetor or engine. Check for fuel blockages, air leaks, etc.

4. Use the throttle cable adjuster to take up most of the slack in the cable. The twist grip should have 10–15° or rotation before the slide begins to rise.

TWIN-CARBURETOR

1. Make sure there is some slack in the main throttle cable so that the slides will close fully.

2. Screw each pilot air screw in gently until it is seated, then back them out 2½ turns.

3. Start the engine. Disconnect one of the spark plug leads and turn the throttle stop screw for the running cylinder in until the engine runs slowly but smoothly on one cylinder.

4. With *both* plug leads connected, rev the engine a few times to clean it out. Then disconnect the *other* plug lead, and turn the throttle stop screw for the running cylinder in until the engine runs slowly but smoothly on the one cylinder.

5. Connect the spark plug lead so that both cylinders will now be running. Idle speed will be very high. Back out each throttle stop screws by equal amounts until an idle speed of 500–750 rpm is obtained.

6. To smooth out the idle, if necessary, turn each pilot air screw in or out by equal amounts. It should not be necessary to turn either of them more than ½ turn. If it is, there is probably a defect in the system: air leaks, fuel flow problem, impure gasoline, etc.

7. Synchronize the throttle slides.

8. Use the adjuster on the main throttle cable so that the slide begin to rise after about 10–15° of twist-grip rotation.

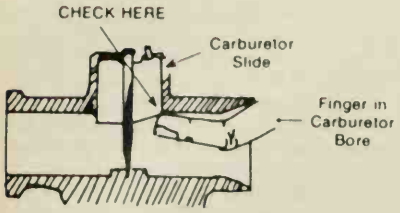
Carburetor Synchronization, Twins

On twin-carburetor models, the throttle slides must be synchronized or one cylinder will lead the other while running. This operation should be carried out after setting the idle speed and mixture.

1. Remove the air cleaner(s).

2. Position a mirror behind the carburetors or reach into the bores with the thumb and index finger of one hand.

3. Twist open the throttle slides, and feel, or watch, as the slides enter the bores. They should begin to enter their respective bores simultaneously.



4. An alternate method is to place a finger on each carburetor slide when closed, and then turn the twist-grip slightly. Both slides should begin to lift at the same time.

5. If adjustment is necessary, use the cable adjusters on the top of each carburetor raising or lowering them so the

Checking carburetor synchronization

slide movements match. Allow each adjuster some part in making the adjustment. Do not screw either of them out too much, or that slide may not close fully.

6. Check the adjustment of the throttle cable(s), using the adjuster(s) near the twist-grip so that the slides begin to rise after about 10–15° of grip rotation.

Triples

Due to type of linkage used, throttle slides should be synchronized first. There are two possible methods:

1. Remove the carburetor assembly from the motorcycle. Looking through the engine side of the carburetors, turn the idle speed screw so that one of the slides (any one) is being held open about 0.010 in. Loosen the locknut and turn the adjuster at the top of each carburetor so that the other two slides are open the same amount. Check by opening the throttles and ensuring that all three slides clear the bore at the same time. Be sure the locknuts are tightened.

2. Alternately, check synchronization with the carbs in place on the machine using sight or feel according to the procedure outlined under "Carburetor Synchronization, Twins," above.

3. With the engine at operating temperature, turn each pilot air screw in until lightly seated, then back each out 2½ turns. Start the engine, and use the idle speed screw to set idle at 500 rpm.

4. Use the cable adjuster at the carburetor end to give about 10–15° of twist-grip rotation before the slides begin to rise.

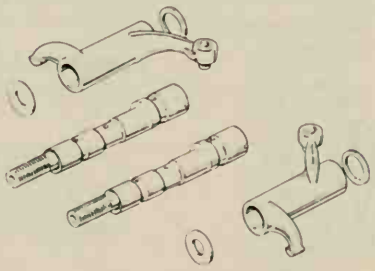
ENGINE AND TRANSMISSION

NOTE: *For engine component inspection and service procedures, refer to "Engine Rebuilding" under the "General Information" section. Triumph engine specifications are given at the end of this "Engine and Transmission" section.*

TR25W

Engine Removal and Installation

1. Remove the fuel tank.
2. Remove the exhaust system by disconnecting the exhaust pipe clamp at the head, and removing the two muffler mounting bolts.
3. Remove the right side-cover and unbolt the skid plate from frame tubes. Drain the oil.
4. Disconnect the valve rocker oil line from the metal T-connection and disconnect the flexible scavenge line from the crankcase line at the rear.
5. Disconnect the alternator, oil pressure switch (if applicable), and contact breaker point leads from their snap connectors at the electrical box. Disconnect the spark plug wire.
6. Remove the carburetor flange nuts and tie the carburetor out of the way. Leave the rubber connecting hose attached to the air filter housing.
7. Disconnect the top engine mount (at the rocker cover).
8. Remove the chainguard front extension and remove the master link from the chain.
9. Disconnect the clutch cable using a suitable box wrench as a lever on the operating arm.
10. Loosen the footpeg mounting bolt and swing the footpeg down.
11. Remove the remaining engine mount bolts. Note that spacers are installed between the engine and frame at the right side of the front and bottom bolts.
12. Remove the rear, engine mounting plate and lift the engine unit out of the frame from the right side.



Installation is in reverse order of removal. Be sure to replace the two spacers correctly. Double-check all hardware and electrical connections when completed.

Top End

REMOVAL

On the TR25W, the cylinder head and barrel may be removed with the engine in the frame. The procedure is as follows:

1. Remove the fuel tank.
2. Unbolt the engine mount at the cylinder head and push the bracket up out of the way.
3. Remove the carburetor from the head, leaving it suspended by the throttle cable.
4. Remove the exhaust system by disconnecting the exhaust pipe clamp at the head and removing the two, muffler mounting bolts.
5. Remove the spark plug and disconnect the rocker oil feed line.
6. Rotate the engine until the piston is at top dead center of the compression stroke (both valves closed, clearance at the rocker arms).
7. Remove the six cylinder head nuts; if the head will not move, free it with a rubber mallet.
8. Lift the head, rotate it around the pushrods to clear the frame, and remove it from the engine.

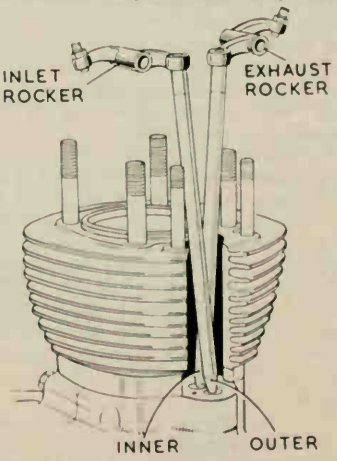
Valve train

9. To remove the barrel, first rotate the engine until the piston is at the bottom of the stroke and then gently lift the barrel off. Steady the piston as the barrel is withdrawn so that it will not be damaged.

10. To remove the piston, it will be necessary to heat it slightly to facilitate removal of the wrist pin. First remove the wrist pin circlips. After the piston is warm, the wrist pin should slide out fairly easily. Mark the front of the piston inside the skirt to facilitate reassembly.

INSPECTION

Refer to "Engine Rebuilding" for service procedures.



Oversized pistons are available in +0.020 and +0.040 sizes.

If the con rod bush must be replaced, refer to the T100C, T100R engine section for removal and installation procedures. Valve guides are removed and installed in the usual manner. The exhaust valve guide is counterbored at the lower end.

INSTALLATION

1. When installing the piston rings, note that the lower compression ring is marked "TOP" and must be installed in the second groove with this mark facing upwards. The top compression ring is probably chromed.

2. Warm the piston and install it, in correct position, on the connecting rod. Insert the piston pin before the piston has a chance to cool. Install *new* circlips and make sure that they are seated properly. Install a new cylinder base gasket and support the piston with two pieces of wood approximately ½ in. square by 6 in. long. Stagger the ring gaps 120 degrees apart, liberally oil the rings, and install a ring compressor. If a ring compressor is unavailable, it is possible to compress the

Pushrod installation

rings by hand, one at a time, as the barrel is slipped over the piston. Be careful. Slide the barrel over the piston and remove the compressor and wood blocks.

3. Install the two pushrods, noting that the outer one operates the intake valve. The top of the exhaust valve pushrod is painted red for identification, as it is slightly shorter than the intake pushrod. *The pushrods must be positioned correctly.*

4. Install the rocker box on the cylinder head using a new gasket, then torque the nuts to 7 ft lbs. Install a new head gasket and fit the head onto the barrel. Place the pushrod ends into the rocker arm ends, making absolutely sure that they are positioned correctly, as illustrated. Keep a light, downward pressure on the head and rotate the engine until the piston is at top dead center of the compression stroke. In this position both valves will be fully closed (clearance at both rocker arms). Tighten the cylinder head nuts, gradually to the figures given in specifications at the end of this section.

5. Check and adjust valve clearances, etc.

Clutch and Primary Drive

DISASSEMBLY

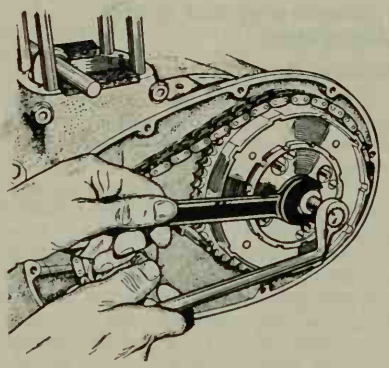
1. If the engine is mounted in the frame, remove the left-side footpeg and brake pedal.

2. Drain the oil from the primary chaincase remove the screws, and take off the primary drive cover. It may be necessary to tap the cover with a rubber mallet to break it free.

3. Remove the four, clutch-spring retaining nuts and withdraw the pressure plate, springs, and cups.

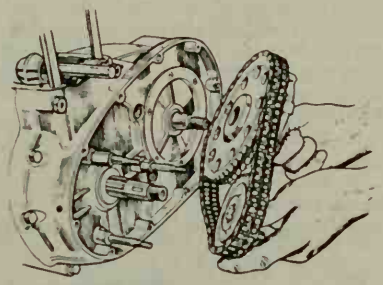
4. Withdraw the clutch plates.

5. Keep the clutch from turning by applying the rear brake, and remove the clutch center nut (after the locktab has been bent back).



6. Remove the locktab and spacer, and withdraw the clutch pushrod.

7. To remove the clutch completely, it is necessary to remove the alternator. To remove the stator (enclosing the rotor), take off the three mounting nuts, pull the alternator lead through the grommet, and pull the stator off the studs.



8. Remove the primary chain tensioner, noting that a spacer is installed on the rear stud.

9. Bend back the locktab and unscrew the rotor nut. Remove the rotor, wipe it clean, and store it in a clean place.

10. Use a gear puller to pull the clutch housing off the transmission mainshaft, while at the same time pulling the front sprocket off the engine crankshaft. Note any shims behind the sprocket.

Removing the clutch housing

Installing the primary drive

INSPECTION

1. If the thickness of the friction discs measures less than 0.137 in., they should be replaced.

2. To examine the dampers located in the clutch center, remove the four screws adjacent to the clutch spring housings and pry off the retaining plate. The dampers need not be replaced unless they are visibly damaged or worn. It may be necessary to lubricate them when installing; it is recommended that a liquid detergent be used. *Do not use petroleum-based oil or grease.*

3. The clutch center slots should be smooth and undamaged or jerky clutch engagement will result. Check clutch spring free length, and if less than 1.60 in., replace the springs as a set.

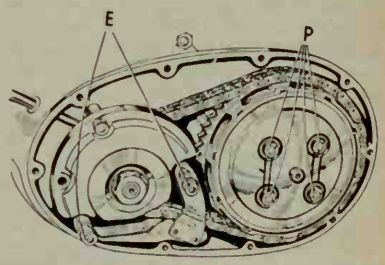
4. The rear sprocket roller bearing is allowed a slight amount of free-play, but, if excessive, the roller should be replaced.

ASSEMBLY

If the sprockets or clutch hub have been replaced it will be necessary to realign the sprockets to avoid excesive primary chain wear. Refer to "Primary Drive Sprocket Alignment." To reinstall the clutch:

1. If the clutch sleeve has been removed, smear it with grease and place the twenty-five bearing rollers in position. Slide the sprocket over the rollers and install the clutch center over the splines of the sleeve.

2. Place the primary chain over the sprockets and position the sprockets on the shafts. Make sure that the transmission mainshaft key is correctly located.



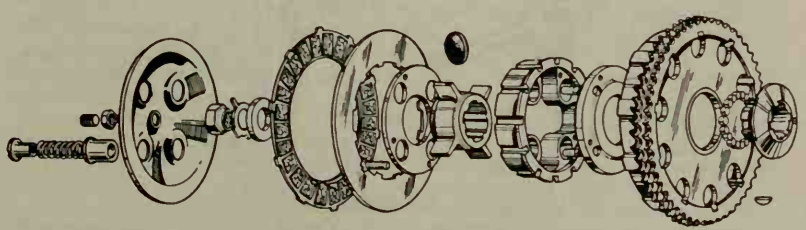
3. Install the clutch center spacer. Make sure that the mainshaft and clutch retaining nut threads are clean and dry. Install a new locktab and apply a small amount of thread-locking compound to the mainshaft threads before installing the retaining nut. Torque the nut to 60–65 ft lb.

4. Install the alternator rotor on the crankshaft with the marks facing out, making sure that the key is located correctly. Install a new locktab, apply a drop of thread-locking compound to the threads, then tighten the retaining nut to 60 ft lbs.

5. Pass the stator lead through the grommet at the front of the crankcase. Fit the stator over the studs and partially tighten the nuts. Check that there is an equal air gap between the rotor and stator at all points using an 0.008 in. feeler gauge. Variations can be corrected by repositioning the stator.

6. To adjust primary chain tension, loosen the rear stator retaining nut and adjust the tensioner to provide ¼ in. free-play on the top run of the chain midway between the sprockets. Retighten the stator nut.

7. Install the clutch discs and plates, alternately, into the clutch housing, beginning with a disc. Insert the clutch pushrod into the mainshaft.



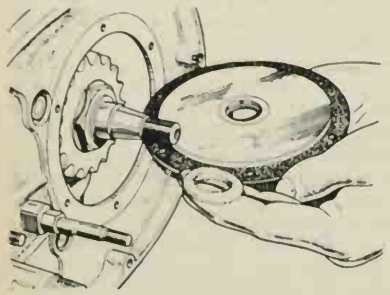
Primary chain (E) and pressure plate (P) adjustment points

8. Install the pressure plate complete with springs and cups. Make sure the spring cup location pips are seated in the slots in the pressure plate.

9. Install and tighten the four spring nuts until the first coil of each spring is just outside of its cup. Improper spring tension will cause excessive pressure at the handlebar lever or clutch slip. Check to see if the springs are tightened evenly by pulling the clutch lever in and kicking the engine over. If any wobble is noticeable at the pressure plate as it turns, tighten or loosen the springs as necessary until it runs true.

10. Adjust the clutch by means of the screw and locknut at the center of the pressure plate so that the clutch operating lever is angled approximately 30° away from the crankcase/side-cover joint.

11. Clean the crankcase and primary cover mating surfaces, apply a thin coat of



Clutch assembly

gasket cement, and mount the cover using a new gasket. If it is possible to use a torque wrench, tighten the screws to 3.5–4.5 ft lbs.

12. Fill the primary chaincase with oil and adjust the clutch lever free-play if necessary.

Transmission Countershaft Sprocket and Oil Seal

To examine or remove the countershaft final drive sprocket, first remove the six screws that retain the plate surrounding the shaft. Pry the plate loose and remove it with its oil seal, taking note of the felt washer that protects the seal from dirt and grit. Check for oil leakage at the back of the plate and replace the plate oil seal if necessary. Install the seal with the lip facing the countershaft sprocket.

Gearbox sprocket cover and seal

If the sprocket teeth are hooked or if the sprocket is damaged, it should be replaced (along with the drive chain and rear wheel sprocket if it too is worn). To remove the sprocket bend back the lock-tab, apply the rear brake, then unscrew the retaining nut. Disconnect the drive chain and pull the sprocket off the shaft. Examine the countershaft oil seal at this time. If it shows signs of leakage, remove the circlip, pry out the seal, and replace it with a new one. Coat the new seal with oil to facilitate installation. Examine the sprocket boss for wear, which may have been causing the seal to leak. Lightly oil the boss when installing the sprocket to avoid damaging the seal. Torque the sprocket retaining nut to 100 ft lbs. When installing the round plate, make sure the gasket is in good condition or use a new one. A new felt washer should be used behind the oil seal. Make sure that the small boss cast into the rear of the plate is installed in the four o'clock position, or else it will contact the drive chain.

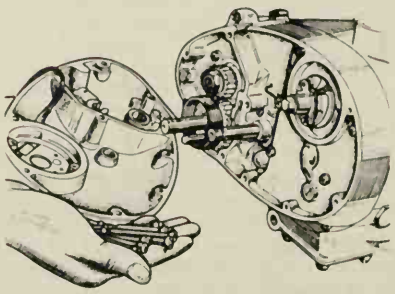
Primary Drive Sprocket Alignment

Assemble and install the clutch unit—without the primary chain—on the transmission shaft. Install the crankshaft sprocket. (The sprocket spacer must be installed with the chamfered end against the sprocket.). Place a straightedge against the sprockets. If the sprockets are aligned properly, the straightedge will make contact both evenly. Shims of different thicknesses are available for installation behind the crankshaft sprocket to correct misalignment.

Transmission and Shifter Mechanism

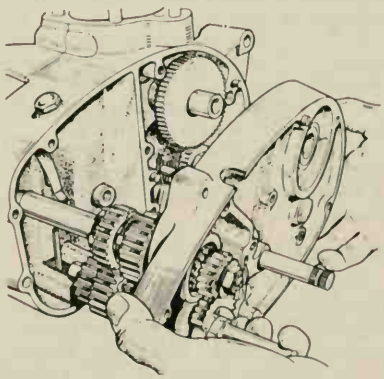
DISASSEMBLY

1. If the top end has not been disassembled, position the piston at top dead center of the compression stroke to avoid distorting the inner camshaft bushing (due to valve spring pressure) as the inner crankcase cover is removed. Drain the transmission oil at this time.



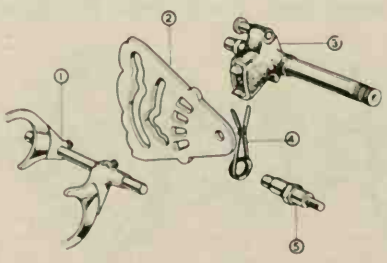
2. Disassemble the primary drive and clutch assembly including the countershaft sprocket, described previously. This is necessary to permit the transmission mainshaft to be withdrawn along with the inner crankcase cover at the right (timing) side of the engine.

3. To remove the right-side outer cover, first take off the kick-start and shift levers. Remove the cover retaining screws, noting that the screws are of different lengths and must be replaced in their original positions.



4. Unscrew the kick-start return spring anchor and remove the spring.

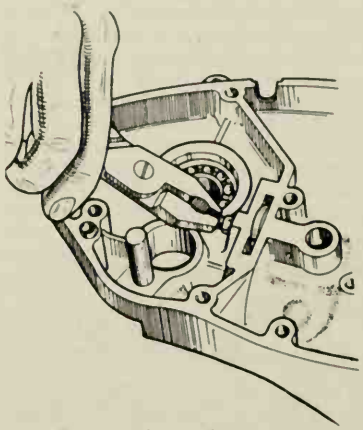
5. Remove the ignition advance unit from the inner cover.



6. Take out the remaining inner cover mounting screws and tap the cover with a rubber mallet to break the joint seal. Withdraw the cover complete with transmission gear cluster. As the cover is removed, exert a slight inward pressure on the end of the camshaft to avoid disturbing the valve timing.

Removing the outer timing cover

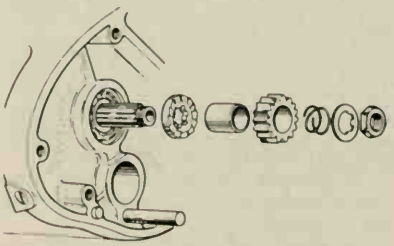
Removing the inner timing cover



Shifter mechanism

7. Depress the two plungers in the shift linkage quadrant and withdraw the quadrant and spring.

8. Remove the camplate pivot cotter pin from the outside of the cover. Screw one of the small inner cover screws into the pivot and pull the pivot out with a pair of pliers.



9. Remove the camplate, shift forks, and fork shaft.

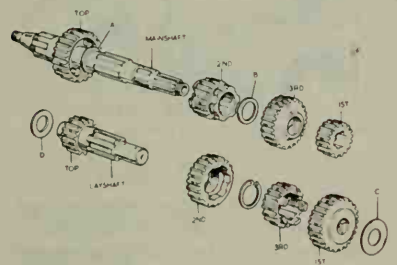
Removing the camplate pivot pin

10. Withdraw the countershaft, complete with gear assembly and mainshaft sliding gear. To remove the mainshaft assembly from the cover, unscrew the kick-start ratchet retaining nut and remove the ratchet components from the shaft.

NOTE: *When removing the countershaft gears, note that second gear is retained by a circlip.*

Kickstarter ratchet assembly

11. The two gears remaining on the mainshaft are an interference fit. Remove by clamping the gears in a vise (protected from the jaws with pieces of wood or cloth) and driving the shaft out using a soft metal drift.



12. If it is desired to remove the left-side transmission bearing from the case, drive the pinion out of the bearing and remove the oil seal. The crankcase should be heated with a propane torch before the bearing is driven out to avoid damage to both the bearing and case.

ASSEMBLY

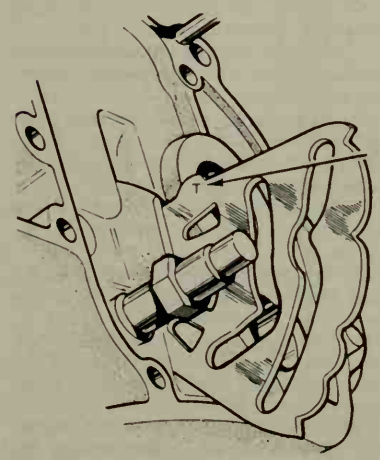
1. To reinstall the left-side bearing (if removed), heat the crankcase very gently

around the area of the bearing housing, moving the torch slowly and evenly to prevent distortion. Install the bearing and fit a new oil seal.

2. If necessary, install a new inner cover bearing, having first heated the cover in an oven. Use new oil seals in the cover.

Transmission gears

3. Install the camplate with the small mark positioned as shown in the accompanying illustration. Install the camplate pivot and lock in place with a cotter pin.



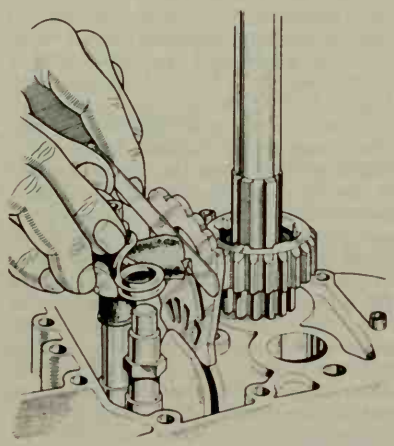
4. Replace the mainshaft gears on the shaft, fit the shaft into the inner cover bearing, install the kick-start ratchet components, and tighten the retaining nut to 50–55 ft lbs. Lock the nut in place with the locktab.

5. Install the kick-start half-gear into the inner cover. Place the cover, with the outside surface down, close to the edge on your workbench so that the half-gear shaft is over the edge but the gear is retained in the cover. Place the countershaft first gear shim over the bearing in the half-gear shaft. Use a small amount of grease to hold it in position.

6. Engage the mainshaft and countershaft first gears and fit the shift fork into the countershaft third gear with the machined (flat) side of the fork up. Engage the roller (button) of the fork in the lower camplate track.

7. Fit the mainshaft second gear with its shift fork (machined side of the fork down) and engage the fork roller in the upper track of the camplate.

8. Insert the shift fork shaft through the forks and into the inner cover. Position the countershaft second gear on the shaft and install the countershaft in the inner cover.



Installing the camplate

9. Place the mainshaft fourth gear thrust washer over the shaft, retaining it with a dab of grease. Install the countershaft thrust washer, making sure that the side with the radius faces the gear.

10. Lubricate all components with motor oil and rotate the shafts to confirm that they are free of binding.

11. If the shift return spring has been removed, it must be reinstalled so that the marked (painted) side of the coil faces the shift quadrant body. If the spring is unmarked, install it in the position in which it appears in the accompanying illustration (in line with the two pins) by trial and error.

Installing the shifter mechanism and return spring

12. Install the shift quadrant assembly into the inner cover, using a flat blade to keep the plungers depressed so they can slide over the camplate.

13. If the inner case, mainshaft, countershaft, or any gears have been replaced, it will be necessary to check end-float of the shafts and adjust if necessary. To accomplish this, mount the inner cover on the crankcase and tighten the screws. Remove the kick-start ratchet assembly and half-gear and the ends of the mainshaft and countershaft will be accessible. Thrust washers of different thicknesses are available to adjust end-float to specification.

14. When all components have been assembled on the inner cover and it is ready to be installed, clean the crankcase and inner cover mating surfaces thoroughly, and apply a thin coat of gasket cement to one of the surfaces. Lubricate the crankshaft oil seal and camshaft end, and mount the cover on the crankcase. Tighten the screws to 3.5–4.5 ft lbs. Check operation of the gears.

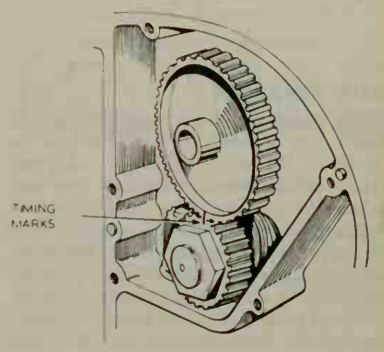
15. Install the outer cover, cleaning the mating surfaces and applying gasket cement as above. Install the kick-start and shift levers.

NOTE: *Before the cover is installed, the position of the shift linkage quadrant can be adjusted for smoother gear selection (late models only). Loosen the adjuster locknut and select each gear in turn. If the gears do not engage positively, turn the adjuster screw a little at a time until gear selection is satisfactory. Do not turn the screw more than ¼ turn from vertical in either direction. Tighten the locknut when adjustment is complete.*

16. Install the primary drive and clutch assembly and refill the transmission and primary case with oil.

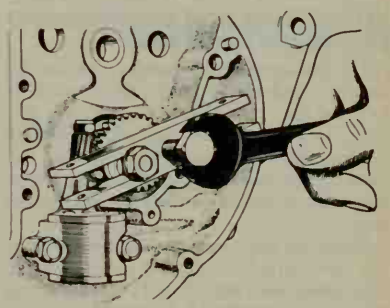
Bottom End

DISASSEMBLY



1. Drain the oil from the engine, transmission, and primary case. Remove the engine.

2. Remove the cylinder head, piston, and barrel.



3. Remove the primary drive and clutch assembly.

4. Remove the right-side outer cover and then take off the inner cover, complete with transmission gearset, as described in the preceding section.

5. Note the alignment of the marks on the timing gears and withdraw the upper gear and camshaft, allowing the tappets to fall clear.

Timing gear marks

Removing the crankshaft pinion

6. Insert a bar through the connecting rod small-end, place blocks of wood under the bar to protect the crankcase, and unscrew the nut at the end of the crankshaft. The bar will keep the engine from turning over as the nut is broken free.

7. Remove the small timing gear with a suitable gear puller.

8. Take off the nut and remove the oil pump drive-gear.

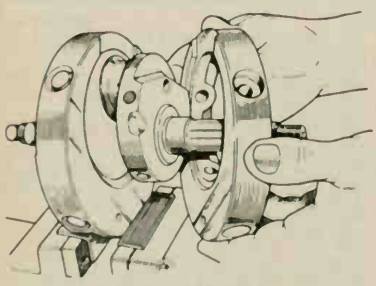
9. From the left side of the crankcase, remove the three bolts at the lower front of the case, the two stud nuts at the center of the case, and the remaining two stud nuts at the cylinder base.

10. Remove the woodruff keys from the crankshaft ends and separate the crankcase halves by tapping with a rubber mallet.

11. Lift away the right crankcase, and remove the crankshaft assembly. Note the number of shims used, if any, between the right-side flywheel and main bearing.

Separating the crankcase halves

MAIN BEARINGS



The inner and outer races of the left-side roller bearing are separated as the crankcase halves are split. The outer race can be driven out after the case has been heated in an oven. The inner race, remaining on the crankshaft, can be pulled off using a suitable gear puller. The right-side (timing side) ball bearing assembly can be driven out after heating the case.

New bearings can be installed in the cases in the same manner, after the cases have been heated.

CONNECTING ROD BEARINGS AND CRANKSHAFT ASSEMBLY

The connecting rod can be removed by simply unbolting the bearing cap. Loosen the nuts alternately, a turn at a time, to prevent distortion. To facilitate reassembly, the connecting rod and cap have been marked with a center punch. Note the direction in which the marks face.

Examine the bearing shells and crankpin carefully for signs of wear, scoring, and other damage. If it is necessary to regrind the crankshaft, bearings are available in 0.010, 0.020, and 0.030 in. undersizes. It is very important that the radius at either end of the crankpin is machined to 0.070–0.080 in. when regrinding. Do not attempt to refinish the bearing shells or file the bearing cap mating surfaces to reduce bearing clearances.

Removing a flywheel

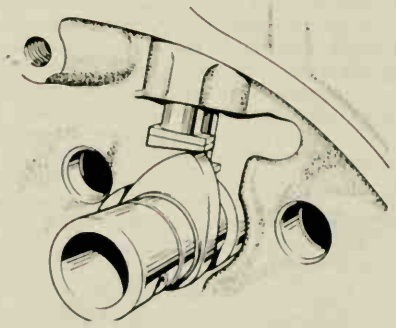
If the crankshaft is to be reground, the flywheels must be removed. Loosen the four, short, flywheel retaining bolts (closest to the crankpin) first to avoid distortion. Remove the remaining four bolts and separate the flywheels. Clean the oil sludge trap, located in the right flywheel. Unscrew the plug and clean the passage with solvent and compressed air.

When reinstalling the flywheels, make sure that the flywheel incorporating the sludge trap is fitted on the *right* side. Apply a drop of thread-locking compound to the threads of each flywheel retaining bolt and tighten evenly to 50 ft lbs.

When installing the connecting rod on the crankshaft, make sure that the rod bearing shells are properly located in the connecting rod and cap. The oil hole should face the drive (left) side flywheel. Lubricate the bearing surfaces with fresh engine oil and install the bearing cap, taking note of the position of the punch marks to ensure that the cap is installed in its original position. It is recommended that new connecting rod bolts and nuts be used as a precaution against breakage. Clean the threads, apply a drop f thread-locking compound, and tighten the nuts to 22 ft lbs. Using a pressure oil can, force oil into the passage at the right end of the crankshaft until it is coming out around the connecting rod bearing. This indicates that the oil passages are not restricted and are full of oil.

ASSEMBLY

1. On the TR25W, the crankshaft end-float must be checked. Proceed with step 2, below, omitting the gasket cement. Check crankshaft end-float, disassemble the cases again and add or remove thrust washers as necessary between the flywheel and right-side main bearing to adjust end-float to within 0.002–0.005 in. Then start with step 2 again and follow the remainder of the assembly procedure.



2. Place the crankshaft assembly into the drive-side crankcase. Clean the crankcase mating surfaces and apply a thin coat of gasket cement to the mating surface of one of the cases. Fit the crankcase halves together and install the three bolts and four nuts. Tighten evenly to 16–18 ft lbs.

3. Rotate the crankshaft to make sure that it turns freely. If it does not, the cause of the trouble must be determined and rectified. Look for incorrect main bearing alignment or insufficient crankshaft endplay.

4. Install the small timing gear on the end of the crankshaft, taking care to locate the woodruff key properly. Tighten the retaining nut to 50–55 ft lbs.

5. Install the oil pump drive-gear on the pump shaft using the special locknut (or a suitable replacement) as originally installed.

6. Place the two tappets into their bores with the thinner end of the tappet foot facing forward. Install the camshaft and timing gear unit, with the timing marks aligned, and fit the thrust washer on the end of the camshaft (late models only).

Note position of tappet contact pad

NOTE: *On early engines there are two marks on the camshaft timing gear—a dash and a V. On these engines the dash must be ignored and the marks aligned as illustrated. On later engines that do not have the V mark, simply align the dash marks.*

7. Install the right-side inner cover complete with transmission gearset and install the outer cover.

8. Install the primary drive and clutch assembly.

T100C AND T100R

Engine Removal and Installation

1. Remove the gas tank and disconnect the spark plug leads.

2. Disconnect the battery terminals and the connectors at the two ignition coils.

3. Remove the ignition coils, taking care not to damage the outer casings.

4. Disconnect the snap connectors between the contact breaker assembly and the condensers.

5. Remove the two cylinder-head torque stays.

6. Disconnect the tachometer drive cable.

7. Remove the carburetor(s) complete with air cleaners.

8. Disconnect the rocker oil feed line, taking care not to bend it.

9. Drain the oil tank and disconnect the delivery lines to the engine.

10. Drain the engine sump, primary chaincase, and transmission.

11. Loosen the clutch adjustment at the handlebar, then disconnect and remove the clutch cable.

12. Remove the exhaust header pipes and mufflers.

13. Remove the final, drive-chain master link and withdraw the chain.

14. Disconnect the alternator leads at their snap connectors underneath the engine.

15. Remove the bolts securing the front engines plates and withdraw the plates.

16. Remove the stud securing the bottom of the engine to the frame and the bolt securing the rear engine plates to the transmission case.

17. Have a helper support the engine, then remove the two nuts securing the right rear engine plate to the frame. Re-

move the plate.

18. Remove the left front stud securing the engine torque stay.

19. Remove the right footrest.

20. With the helper, lift the engine out the right side of the machine.

21. Installation is basically a reversal of the removal procedure. Note the following:

a. When the engine is in position in the frame, install the bottom frame bolt first, then install the right rear engine plate and tighten the bolts fingertight only.

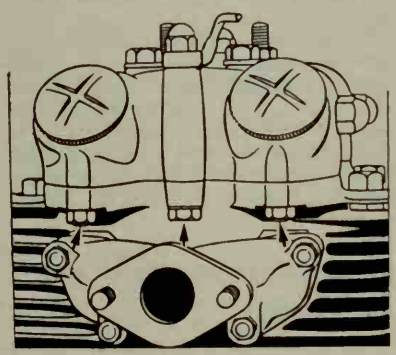
b. Install the front, engine mounting plate, then tighten all mounting bolts snugly.

Top End

REMOVAL

The cylinder head and barrel can be removed without taking out the engine.

1. Disconnect the leads from the battery terminals and remove the fuel tank.



2. Disconnect the high tension cables and wiring harness from the ignition coils, then remove the coils. Take care not to damage the coil outer casings.

3. Remove the cylinder head torque stays.

4. Remove the rocker oil feed line.

5. Remove the two nuts from the studs at the bottom of the exhaust rocker box.

6. Remove the two phillips screws from the top of each rocker box, loosen all eight cylinder head bolts and remove the central head bolts.

Rocker box stud nuts and bolt (500)

7. Remove the exhaust rocker box, then remove the intake rocker box in the same manner. Take care not to lose the six plain washers (one under each bottom securing nut).

8. Remove the pushrods and mark them for reassembly position.

9. Remove the exhaust header pipes.

10. Disconnect the fuel lines and plug the ends. Disconnect the throttle linkage at the carburetor(s).

11. Remove the remaining four cylinder head nuts by turning each one a little at a time in an X pattern.

12. Remove the cylinder head complete with intake manifold(s) and carburetor(s). If the cylinder head is being serviced, rather than being removed to gain access to another part of the engine, remove the intake manifolds and carburetor(s).

13. Remove the pushrod tubes, remembering to replace the rubber seals during assembly.

14. Remove the cylinder head gasket.

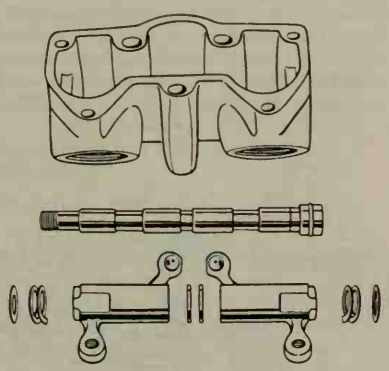
15. Wedge a piece of rubber between the intake and exhaust tappets to prevent them from falling into the case when the barrel is removed.

16. Rotate the engine until the pistons are both at TDC, then remove the eight cylinder base nuts and washers.

17. Raise the barrel high enough to stuff some clean, no-lint rags into the case openings. It is also a good idea to fit some kind of rubber protectors over the cylinder studs to prevent damage to the connecting rods when the barrel is removed.

18. Lift off the barrel carefully, supporting the pistons when they are free.

19. Remove and mark the tappets for reassembly.

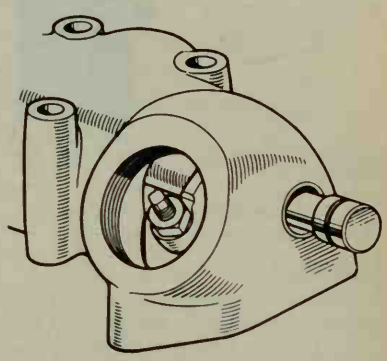


ROCKER BOXES

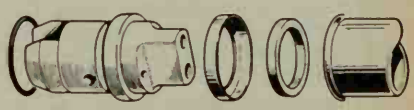
The rocker spindles can be removed by driving them out with a suitable drift. Once out, the spindles will release the rocker arms and washers. Clean the parts in kerosine or a cleaning solvent, then blow them dry with compressed air. Also blow out the spindle oil drillings with compressed air. Upon reassembly, the spindle oil seals should be replaced.

If the rocker ball pins require replacement, drive them out with a suitable drift and press the new ones in with the drilled flat toward the rocker spindles.

The rocker boxes can be reassembled using a $^{7}/_{16}$ in. x 6 in. bar, ground to a taper at one end. This bar serves as an alignment tool for the spindles. Before beginning assembly, note that two of the washers removed from the spindles have a smaller diameter than the other washers. These are thrust washers and they must be assembled last—against the right inner face of the rocker box.



Grease two plain washers and position them on either side of the center bearing boss. Position the left rocker arm, bringing it into line with the alignment bar, and locate the plain washer, spring washer, and thrust washer as shown in the accompanying illustration. Repeat this for the right rocker arm, then oil the spindle and slide it as far into the rocker box as possible. Tap it in the remaining distance with a soft-faced hammer.



Rocker arms and spindle (500)

TAPPETS AND GUIDE BLOCKS

The only wear likely to be apparent on the tappets is at their tips which are plated with Stellite. Over a long period of time, an indentation will be worn in the center of the tip. If the width of this indentation exceeds $^{3}/_{32}$ in., replace the tappet.

Installing the rocker box spindle

Tappet guide block assembly

It is not necessary to remove the press-fit tappet guide blocks to check their condition. Simply insert the tappet and rock it back and forth in the block. There should be little or no lateral play. See specifications for allowable clearances.

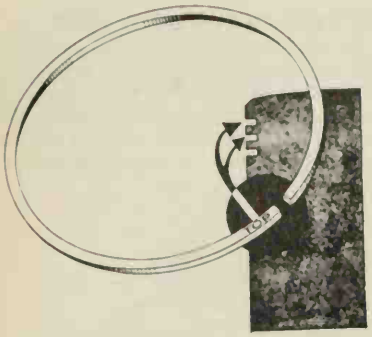
CYLINDERS

The difference between the largest and smallest of the six bore measurements must not exceed 0.13 mm (0.005 in.), or reboring is necessary.

PISTONS

1. Remove the inner and outer piston pin retaining circlips, then attach a piston pin removal tool and press out the pin.

2. Lay out and mark the pistons, piston pins, and retaining circlips for reassembly.



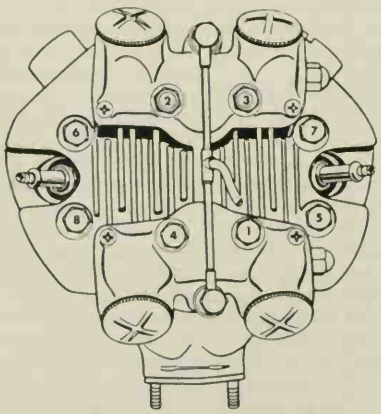
3. Remove the piston rings one at a time by lifting an end of the ring out of its groove and holding a thin piece of metal between it and the piston. Slide the piece of metal around the circumference of the piston while at the same time gently lifting the raised part of the ring upwards.

4. Replacement pistons are available in three oversizes. These sizes and the corresponding recommended cylinder bore sizes are given in a chart at the end of this section.

5. Install the piston rings one at a time over the top of the piston. Note that the two compression rings are marked TOP, which must face upwards when the rings are fitted.

6. Position the piston on the connecting rod.

7. Install one new retaining circlip as a stop, then press the piston pin into position and install another new circlip on the other side.

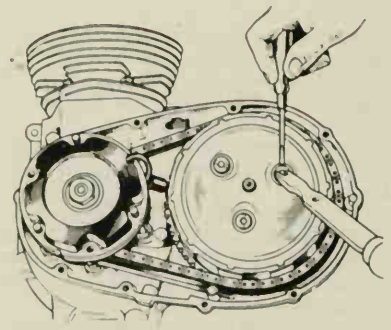


Install compression rings with the "Top" mark facing upwards

NOTE: *It is advisable to heat the piston to 100° C prior to assembly.*

ASSEMBLY

1. Position new guide block O-ring seals at the base of the cylinder block.
2. If it was removed, lightly grease the outside surface of the exhaust guide block, then carefully align the guide block and cylinder locating holes and drive the block into position with Triumph special tool no. Z23 or a suitable drift.
3. Repeat the above step for the intake guide block, then install the locking bolts.
4. After installing the guide blocks, make sure that the exhaust guide block oil drillways are free from obstruction.
5. Install the tappets in the guide blocks after thoroughly lubricating them with oil. Wedge them in position.
6. Install the cylinder base gasket, making certain that the gasket does not obscure the oil feed drillway in the crankcase.
7. Fit ring compressors over the piston rings, then carefully slide the cylinder down over the pistons. Remove the ring compressors as soon as the rings are positioned within the cylinder. Continue lowering the cylinder block and then remove the rags in the crankcase openings as late as possible.
8. Install the cylinder base attaching nuts.
9. Replace or anneal the cylinder head gasket.
10. Clean the mating cylinder head and cylinder surfaces, then grease the gasket and position it on the cylinder.
11. Coat the tappet guide blocks with grease and position the pushrod cover tubes with new O-rings seals.
12. Position the cylinder head and install the four outer and one central head bolt finger-tight.
13. Place a small amount of grease in the bottom cup of each pushrod, then locate the intake pushrods in their respective bores. This will have to be done by "feel."
14. When the pushrods are properly positioned, remove the spark plugs and turn the engine over until both intake pushrods are level and at the bottom of their travel.
15. Install the intake rocker box.
16. Repeat the above procedure for the exhaust rocker box, noting that the central cylinder head bolts should be tightened to torque specifications before tightening the underside securing nuts.
17. Turn the engine over several times to make sure the valves are operating properly, then reinstall the torque stays and secondary ignition coils.
18. Connect the rocker oil feed line, using either new copper washers or annealed, used ones.
19. The remainder of the assembly procedure is a reversal of the disassembly instructions. Adjust valve tappet clearances.



Cylinder head bolt tightening sequence

Clutch

DISASSEMBLY

1. Remove the left exhaust header pipe.
2. Loosen the rear brake adjustment until the pedal drops clear of the primary cover.
3. Remove the left footrest.
4. Drain the oil from the chaincase, then remove the chain tension adjuster.
5. Remove the ten, recessed cover-securing screws and withdraw the cover and paper gasket.
6. Remove the chain tensioner assembly.
7. The clutch pressure plate is held in place by three, slotted adjuster nuts. To remove these nuts, slide a knife or screwdriver blade under the nut and loosen it with Triumph tool no. D364 (supplied with tool kit) or a suitable substitute.

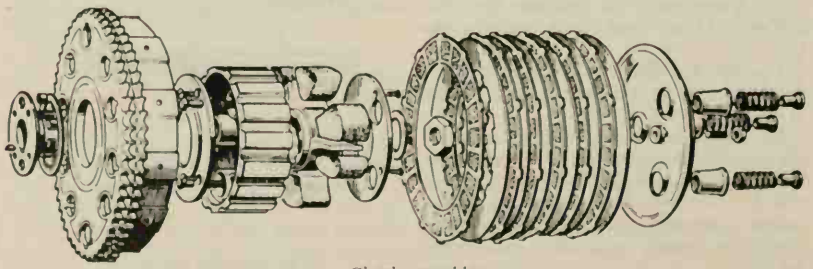
NOTE: *The clutch nuts are fitted with locking tabs which may be sheared off by removal. If so, replace them.*

Removing the clutch nuts

8. Remove the clutch springs, cups, and pressure plate assembly.
9. The clutch plates can be removed with the use of two, narrow, hooked tools made of 1/32 in. wire.

INSPECTION

1. If the thickness of the discs is 0.030 in. (0.75 mm), or more, less than specified, they should be replaced.
2. Check the fit of the plate on the shock absorber unit. There should be little radial clearance.
3. Measure the clutch spring length and compare with specifications. If a spring has shortened by 0.10 in. (2.5 mm) or more, replace the set.



ASSEMBLY

1. Install the clutch plates and discs; the innermost position must be occupied by a bonded plate.
2. Install the cups, pressure plate, springs, and slotted adjuster nuts.
3. True the clutch pressure plate by first tightening the pressure-plate, slotted adjuster nuts until they are even with the clutch pins, and then by kicking the engine over and observing the rotation of the plate, and then making any necessary adjustment until the plate turns evenly. If the plate wobbles even slightly, it must be corrected.

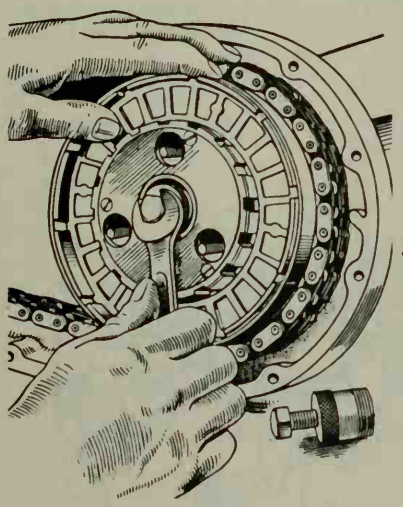
Primary Drive and Clutch Hub

DISASSEMBLY

1. Remove the primary cover as previously described.
2. Remove the clutch assembly as previously described.
3. Disconnect the alternator stator leads at their snap connectors under the engine.
4. Remove the three stator securing nuts and withdraw the stator from over its mounting studs. Unscrew the sleeve nut

Clutch assembly

and then the lead can easily be removed.



5. Remove the rotor.

6. Remove the rotor key and distance piece.

7. Remove the clutch hub securing nut and cup.

NOTE: *Machines prior to serial no. H49833 have a tab washer and a different cup washer, rather than the self-locking securing nut.*

8. Screw the body of extractor no. Z13 into the clutch hub until it bottoms, then tighten the center bolt until the hub is released.

Removing the clutch housing

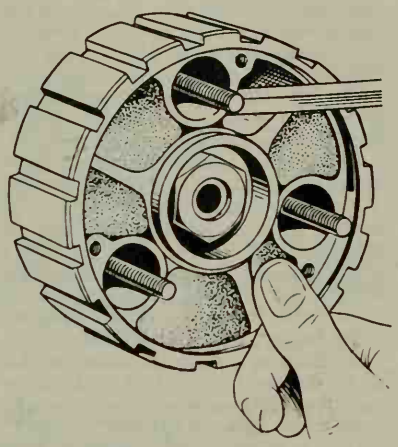
9. Assemble extractor no. Z151 and D662/3 on the engine sprocket and tighten its center bolt until the engine sprocket is released.

10. Withdraw the engine sprocket, clutch hub, and primary chain together.

11. Remove the transmission mainshaft key and check the oil seal for leakage.

INSPECTION

1. Inspect the clutch shock absorber for worn rubbers or punctures. They can be removed by prying them out, small rubbers first. Replace as necessary. When reassembling, apply thread-locking compound to the cover plate securing screws.



2. First thoroughly clean the primary chain then check it for wear by scribing two marks on a flat surface 12 in. apart, and centering two pivot pins at the scribe marks. Fully compressed, the chain link pivot should line up with the marks; fully stretched, it should not extend more than ¼ in. beyond the marks.

3. Check the fit between the shock absorber spider and the clutch hub splines. The spider should be a push fit on the clutch hub, with no radial movement.

4. Check the fit of the engine sprocket on the crankshaft in the same manner. There should be no radial movement.

5. Check the clutch hub bearing diameter, rollers, and clutch sprocket bearing. Replace any bearing rollers that are pitted or worn. See specifications.

6. Make sure the shock absorber spider is a good fit in the inner and outer

Installing clutch hub rubbers

retaining plates, and that the arms have not excessively scored the inner surface of the retaining plates.

ASSEMBLY

1. Grease the clutch hub and install the thrust washer and twenty of the correct rollers. Do not use ¼ in. x ¼ in. rollers!.

2. Position the hub and press the shock absorber, complete with the three threaded pins, on the hub.

3. Install a new tapered distance collar behind the engine sprocket, with the taper toward the crankshaft main bearing and oil seal.

4. Install the transmission mainshaft key and tap the clutch hub onto its taper.

5. Lubricate the primary chain and lay it over the clutch sprocket.

6. Wrap the chain around the engine sprocket, then position the sprocket on the crankshaft.

7. Place clutch locking tool Z13 in the clutch plate housing, then install the cup washer and self-locking nut. Torque the nut to specifications.

NOTE: *On machines before serial no. H49833, install the tab washer with the long tab in the hole in the shock absorber spider, install the securing nut and bend a tab to lock the nut.*

8. Install the alternator rotor, making sure that the key or locating peg is correctly positioned.

9. Install the alternator stator. Put a 0.008 in. (0.2 mm) feeler gauge between each stator pole and the rotor. Turn over the engine to make sure that the rotor and stator do not touch.

Transmission Countershaft Sprocket

REMOVAL AND INSTALLATION

1. Disassemble the clutch and primary drive as previously described. Remove the sprocket cover.

2. Bend back the tab washer and, while holding the rear brake, remove the sprocket securing nut.

3. Slide off the final drive chain and remove the countershaft sprocket.

4. Make sure the oil seal is in good condition, then lubricate the ground boss of the new sprocket and position it on the transmission mainshaft.

5. Replace the tab washer, screw on the securing nut finger-tight, then, with the chain in place, tighten the nut to torque specifications.

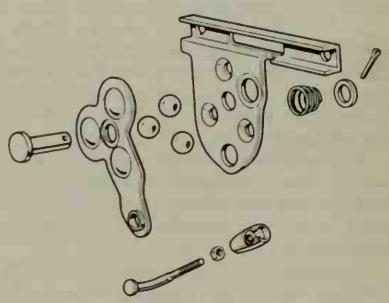
6. Oil the bushing that protrudes from the mainshaft high gear and install the sprocket cover with a new paper gasket.

7. The remainder of installation is a reversal of the removal procedure.

Clutch and Shifter Operating Mechanisms

DISASSEMBLY

1. Remove the right exhaust header pipe and footrest.



2. Drain the gearbox oil.

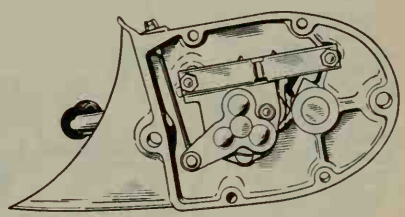
3. Disconnect the clutch cable from the actuating lever.

4. Remove the two nuts and four recessed screws that secure the gearbox outer cover. Remove the kick-starter.

5. Hold the gearshift lever in one hand, then tap the cover with a soft-faced mallet until it is free to be removed.

6. Unscrew the two nuts inside the gearbox outer cover and remove the shifter return springs complete with the thrust buttons and distance pieces.

Clutch operating mechanism



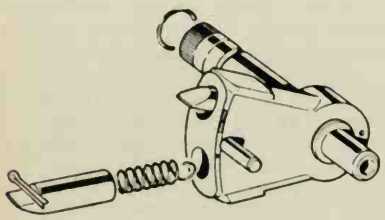
7. Unscrew the countersunk screw that secures the clutch operating mechanism and withdraw the assembly.

8. Remove the shifter lever pinch bolt, remove the lever, and then withdraw the shaft from the cover.

9. Remove the cotter pin from the clutch operating shaft. This will release the clutch operating balls.

10. Remove the two cotter pins and disconnect the plungers and springs from the shifter quadrant.

11. If the shifter spindle bushing requires replacement, heat the outer cover to 100° C and drive it out with a suitable, shouldered drift. Drive in the new bushing before the cover has a chance to cool.

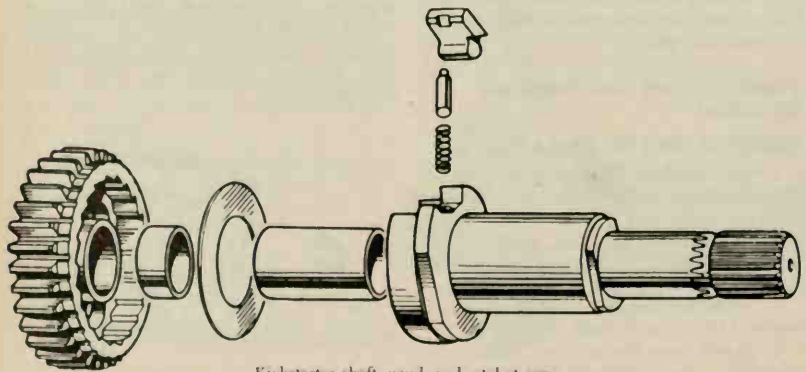


Clutch mechanism installed

NOTE: *A drift for removing and installing the shifter spindle bushing can be made from a piece of ¾ in. diameter bar. Machine the bar to a diameter of ⅝ in. and cut a length of ¾ in.*

ASSEMBLY

1. Install the shifter quadrant springs, plungers, and securing cotter pins, then install a new O-ring on the spindle.
2. Lubricate the spindle and O-ring with oil, then insert the spindle in the cover.
3. Assemble the clutch-operating mechanism balls in their recesses and install the shaft and clutch lever in the order shown in the accompanying illustration. Don't forget to install the spring and washer before replacing the cotter pin.

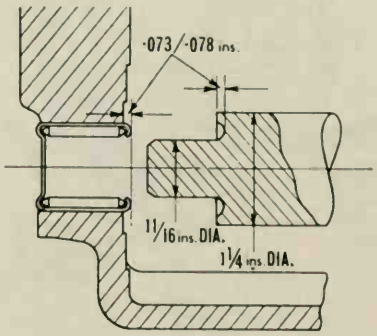


Shifter mechanism

4. Install the distance collar on the end of the shifter quadrant shaft, then install the clutch operating mechanism in the cover and secure it in place with the countersunk screw.
5. Install the distance pieces over the studs, then connect the shifter return springs and thrust buttons. Install the return spring cover plate and tighten the securing nuts.
6. Install the gearbox outer cover with sealant, tighten the securing screws, and install the kick-start lever.
7. Refill the transmission with oil.

Gearbox and Kick-Starter Mechanism

DISASSEMBLY



1. Disassemble the primary drive and clutch as previously described. Remove the transmission mainshaft nut and key.
2. Remove the gearbox outer cover, noting that the gearbox should first be positioned in fourth gear.
3. Remove the two inner gearbox cover retaining screws, then remove the entire gearbox assembly by tapping the clutch end of the mainshaft with a mallet.
4. Remove the camplate cotter pin, then withdraw the camplate spindle.
5. Pry off the kick-starter return spring and remove the distance piece. Withdraw the kick-starter spindle.
6. Remove the camplate index plunger and place it aside.
7. Remove the selector fork spindle and disengage the selector forks from the camplate.
8. Remove the layshaft and kick-starter pawl, plunger, and spring.
9. Drive the mainshaft assembly out of the bearing with a soft-faced mallet.
10. Remove the countershaft sprocket as previously described, then drive the mainshaft high gear into the gearbox with a soft metal drift and hammer.
11. To remove the mainshaft right bearing, heat the cover to 100° C and drive it out with a suitable, shouldered drift. Install the new bearing while the cover is still hot. Replace the securing circlip.
12. To remove the high gear bearing on the left side of the machine, pry out the oil seal and remove the retaining circlip. Heat the case around the bearing to 100° C, then drive it out with a suitable, shouldered drift. Install the new bearing while the case is still hot. Replace the oil seal with the lip and spring toward the bearing, then replace the retaining circlip.
13. If it is necessary to replace the mainshaft high gear bushing, press it out with a drift measuring 5.0 x ⅞ in., having ¾ in. of one end machined to 13/16 in. diameter. Install the new bushing with the same drift, making certain the bushing oil groove is at the gear teeth end. The bushing should then be reamed to the size given in specifications.
14. The layshaft right needle roller bearing can be removed by heating the kick-starter spindle to 100° C and tapping it off with a block of wood.
15. The layshaft left needle roller bearing is of the closed-end type and can be removed through the countershaft sprocket cover plate aperture. Heat the case to 100° C and drive the bearing into the gearbox with a suitable drift. Install the new bearing while the case is still hot. A special drift, for which dimensions are given in the accompanying illustration, must be used to install the new bearing.

Kickstarter shaft, pawl, and ratchet gear

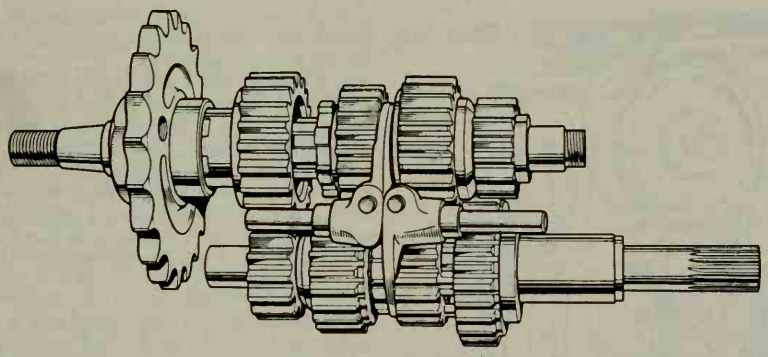
ASSEMBLY

1. If all replacement bearings have been installed with new seals and circlips, install the layshaft thrust washer over the needle roller cage, and hold it in position with a dab of grease.
2. Lubricate the mainshaft and layshaft captive gears, then assemble the mainshaft in the inner gearbox cover.
3. Install the plunger, spring, and pawl on the kick-starter spindle, then insert the assembly in the inner gearbox cover and slide the layshaft assembly into the kick-starter bearing. Remember to install the mainshaft distance piece between the mainshaft assembly and the main bearing in the inner cover.
4. Position the selector forks on the shafts as shown in the accompanying illustration and insert the selector fork spindle to hold them in position.

5. Assemble the camplate in the outer cover and locate the selector fork rollers in their camplate tracks.
6. Install the camplate spindle and secure it with a new cotter pin. Install the camplate index plunger and spring.
7. Operate the selector forks manually to make sure that each selector fork is on its appropriate shaft. When the camplate is moved to its full extent, both selector rollers should move to the full extent of the camplate grooves in both directions. If not, the selector forks will have to be disengaged and reversed.
8. Install the distance piece over the kick-starter shaft, then secure the end of the return spring with its retaining screw.

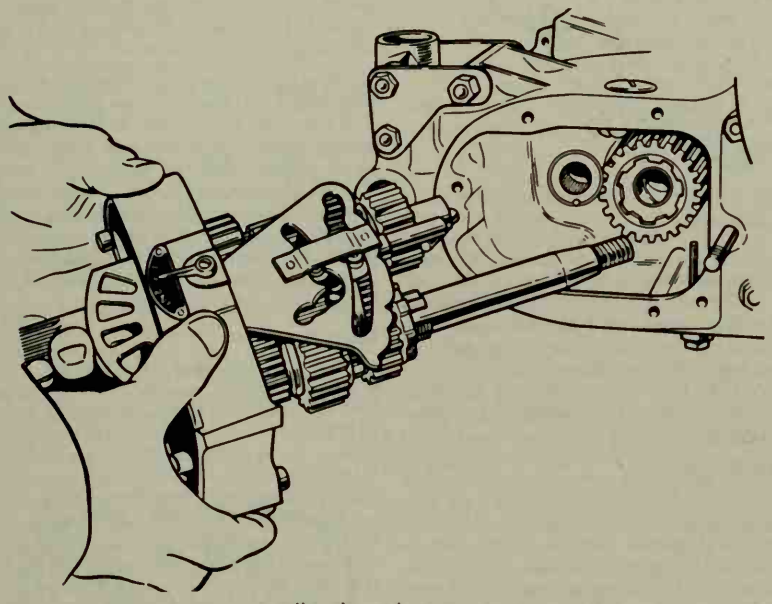
NOTE: *Use a screwdriver to tension the return spring before connecting it and installing the return spring plate.*

9. The remainder of the assembly procedure is a reversal of the disassembly instructions.



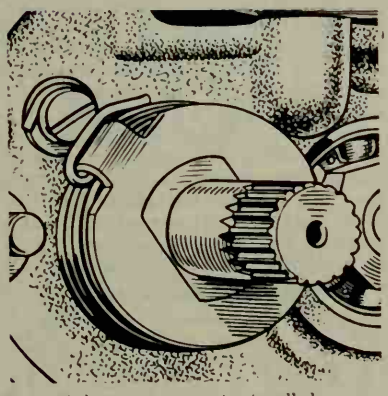
Bottom End

CAMSHAFT SERVICE (ENGINE INSTALLED)



It is not necessary to separate the crankcase halves in order to replace the camshafts.

Removal and Installation

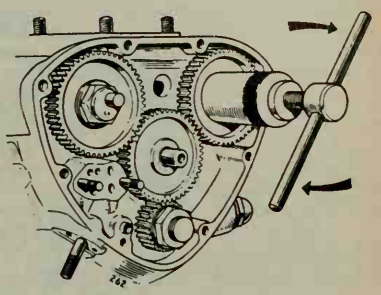


1. Remove the rocker boxes.
2. Remove the timing cover.
3. Remove the oil pump (see "Lubrication Systems"), and temporarily block the crankcase holes to prevent oil spillage. Make sure you remember to open these holes before reinstalling the oil pump.

Gear cluster and shift forks

Installing the gearbox components

Kickstarter return spring installed



4. Extract the intake and exhaust camwheels. The camshaft retaining plates can now be seen.

5. Carefully pull the camshafts out the right side of the machine. Make sure the breather disc and spring, located behind the intake cam, do not fall into the crankcase. Also, lean the machine to the left when removing the cams so that the cam followers do not fall into the crankcase.

6. Assemble the rotary breather valve and spring to the new intake camshaft, then install both cams, making certain that the slot in the end of the intake cam fully engages the dog on the breather valve.

7. Reinstall the camshaft retainer plates and secure them in place with new screws.

8. The remainder of the assembly procedure is a reversal of the removal instructions.

Removing a camshaft gear

CRANKCASE

Disassembly

1. Remove the primary chaincase cover and disconnect the alternator leads under the engine.

2. Remove the three screws that secure the alternator stator, and pull the stator off its mounting studs. Do not disconnect the leads at this time.

3. Disassemble the clutch and primary drive as previously described. Remove the stator sleeve and withdraw the stator leads.

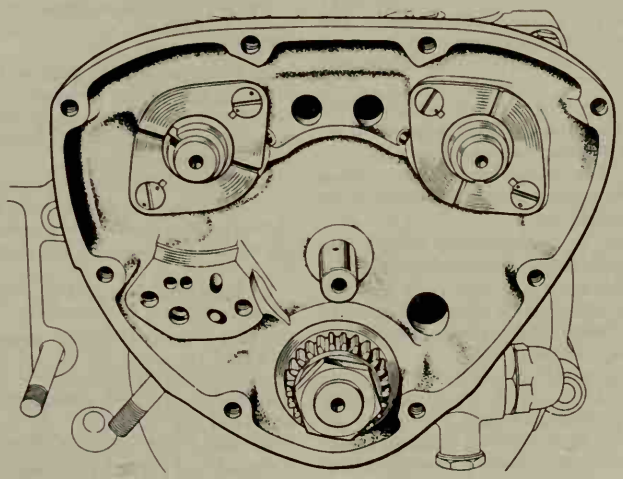
4. Remove the gearbox outer cover and dismantle the gearbox.

5. Remove the rocker boxes, cylinder head, cylinder barrel, and pistons.

6. Disconnect the clutch cable and remove the carburetor(s).

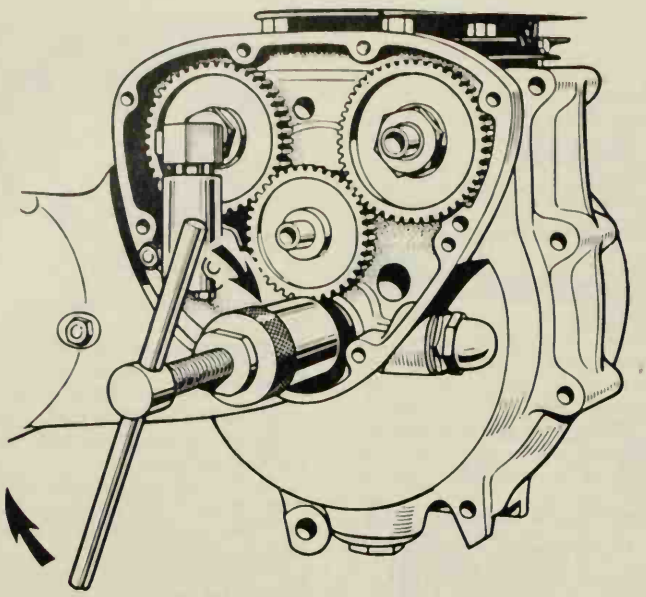
7. Remove the contact breaker cover and the oil pump, then remove the crankshaft pinion. The camshaft pinions can also be removed at this time.

NOTE: *The crankshaft pinion nut has a right-hand thread, but the camshaft nuts are left-hand threads.*



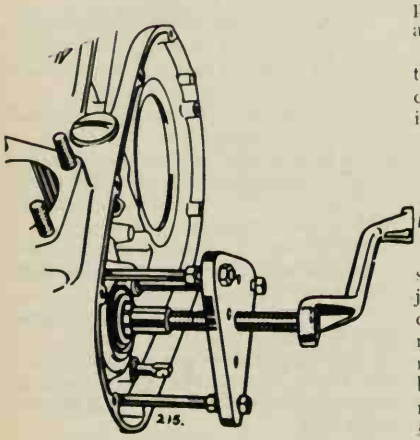
8. Remove what's left of the engine from the frame.

9. Clamp the crankcase firmly in a vise at the bottom mounting lug and remove the bolt and two screws at the cylinder base.



10. Remove the stud at the front of the engine and the two nuts next to the gearbox housing.

11. Attach Triumph extractor no. Z151 and separate the cases.



12. After the cases are apart, remove the crankshaft assembly. Remove the

Camwheels removed, revealing camshaft retaining plates

breather valve from within the intake camshaft bushing in the left case.

Crankshaft and Connecting Rods

DISASSEMBLY

1. Clamp the crankshaft assembly in a soft-jawed vise and place a rag over any sharp edges to protect the connecting rods.

2. Unscrew the cap retainer nuts a little at a time to avoid distortion, then remove the caps and connecting rods.

NOTE: *The connecting rods, caps and nut are center-punched to facilitate reassembly.*

3. Using a large impact driver, unscrew the oil tube retainer plug from the right end of the big-end journal. If necessary, drill a hole ⅛ in. deep and ⅛ in. in diameter to eliminate the locking effect of the plug center punch.

4. Remove the flywheel bolt next to the big-end journal, then pull out the oil tube with a hooked piece of stiff wire through the flywheel bolt location hole.

5. Thoroughly clean all parts in solvent, then blow them dry with compressed air. Make sure the oil drillways are blown clear.

6. To remove the flywheel, unscrew the two remaining bolts and press the crankshaft out of the right side plain bearing with a five ton press.

NOTE: *Before removing the flywheel, make certain it is marked for reassembly.*

INSPECTION

Inspect the big-end journals for any signs of scoring, etc., and measure the journal diameter. Compare with specifications. Light score marks can be removed with fine grade emery cloth, but make sure all metal filings are removed before reassembly. If the scoring is light, new connecting rod shell bearings should be installed; if the scoring is extensive, the journals should be reground to an appropriate undersize.

NOTE: *The replaceable big-end bearing shells are pre-sized to give the correct dimensions. Under no circumstances should they be scraped, or the connecting rod and cap filed to alter the bearing dimensions.*

ASSEMBLY

1. Position the oil tube in the crankshaft, aligning the flywheel bolt holes with those in the crankshaft. Temporarily install one of the flywheel bolts to secure it in position.

2. Apply thread-locking sealant to the oil tube plug and install it in the crankshaft. Center-punch the crankshaft opposite the slot to lock the plug in position.

3. Heat the flywheel to 100° C, then position it over the crankshaft with the center punch mark to the right. Turn the flywheel through 180° to get it over the crankshaft web, then turn it to the correct position relative to the crankshaft and align the bolt holes.

4. Coat the flywheel bolt threads with a thread-locking sealant, then install and torque them to specifications.

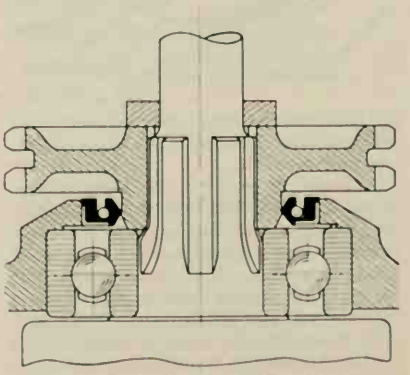
5. If a new or reground crankshaft, or a new flywheel was installed, the assembly should be rebalanced.

6. Check to make sure all the oil drillways are free from obstruction, then install the connecting rods and caps. Torque the retaining nuts to 27 ft lbs.

7. Last, force oil through the crankshaft, right main-bearing journal drillway until it is expelled at both big-end bearings. This will provide assurance that the drillway is free from obstruction.

Camshaft Bushings

The intake and exhaust camshafts run in bronze bushings in the left case and are butted directly into the right case. To remove the bushings in the left case, a tap will be necessary. The ideal size is ⅞ in. diameter x 9 whitworth.



When a good thread has been cut in the bushing, heat the case to 100° C and screw in the appropriate bolt. Grip the bolt in a vise and tap the case with a soft-faced mallet until the bushing is free. The replacement bushings are pre-sized but will require a light reaming to meet specifications. After reaming the new bushings, make sure the crankcase is thoroughly cleaned to remove any metal filings.

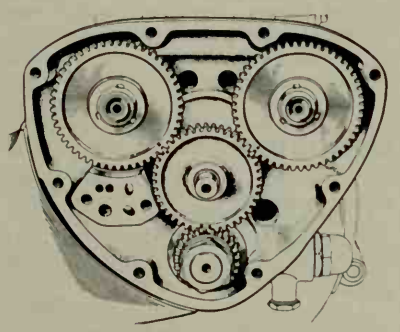
Main Bearings

To remove the left main bearing heat the case to 100° C and drive it out with tool no. Z14. The right main bearing prior to H65573 is a bronze bushing, and is removed by first removing the lock plate, heating the case to 100° C, then driving it out with a suitable, shouldered drift. It is advisable to replace the left bearing oil seal while the engine is apart, even if it appears to be in good condition. This is installed with the open face outwards.

To install the left bearing, first make sure that its housing is clean, then heat the case to 100° C and drive the bearing into position with a tubular drift the same size as the bearing outer race. A suitable size would be 2¾ in. diameter x 6 in. long.

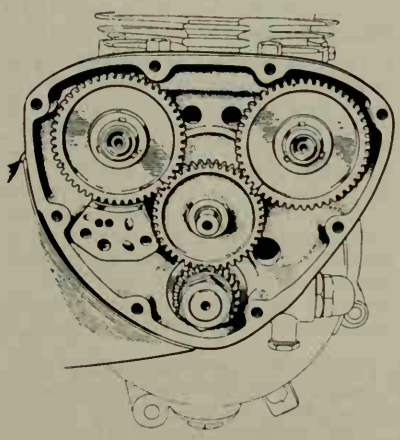
To install the right bronze bushing, heat the case to 100° C and then press the bushing into position. Let the case cool, then line-ream the bushing to specifications. Tool no. Z134 is available for this purpose. To use it, the case halves must be assembled and the reamer inserted through the right main bearing, with the

Left main bearing oil seal installation



pilot end located in the left main bearing. Reamer Z134 is also available in 0.010, 0.020, and 0.030 undersizes.

After H65573 the right bearing is the ball-type and is removed and installed in the same manner as the left bearing.



After both bearings have been installed, press the oil seal into the left case, open face outwards.

Assembly

1. Thoroughly clean the mating crankcase halves, giving special attention to the locating dowels.
2. Position the left case on two wooden blocks, lubricate the main bearing and camshaft bushings and then install the breather valve and spring in the intake cam bushing. Assemble both camshafts, making sure the intake cam slot engages the breather valve dog.
3. Carefully install the crankshaft assembly, making sure the fit in the bearing is good.
4. Apply fresh joining compound to the mating surfaces, then position the connecting rods in the center and lower the right case over the crankshaft. When the halves are mated, check to make sure the crankshaft and camshafts are not binding. The crankshaft should rotate freely, while the camshafts should offer only slight resistance.
5. The remainder of the assembly procedure is a reversal of the disassembly instructions. Make sure all timing pinions are correctly located.

Timing marks (T100C)

Timing marks (T100R)

650 AND 750 TWINS

Engine Removal and Installation

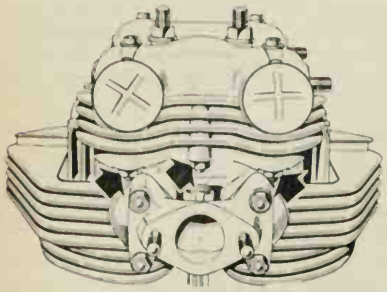
TR6R, TR6C, AND T120R

1. Turn off the fuel petcock, then disconnect and plug the fuel lines.
2. Remove the three securing bolts and the fuel tank.
3. Remove the main fuse from its holder, then disconnect the right and left ignition coil leads.
4. Remove the securing bolts and the two ignition coils. Disconnect the oil pressure switch on the timing cover.
5. Remove the attaching nuts and bolts, then remove the front and rear torque stays from the cylinder head.
6. Disconnect the tachometer drive cable from the right-angle gearbox at the front of the engine.
7. Disconnect the throttle cable at the carburetor(s).
8. On single carburetor engines, remove the air cleaner.
9. Remove the carburetor(s).
10. Disconnect the rocker oil feed line, taking care not to bend it excessively.
11. Drain the engine sump, oil tank, and transmission.
12. Disconnect all lines from the oil tank.
13. Back off the clutch adjustment at the handlebar until there is plenty of slack, then disconnect the cable at the operating arm on the right side of the engine.
14. Remove the exhaust headers and mufflers.
15. Disconnect the final drive-chain master link and remove the chain.
16. Disconnect the two generator leads at the bottom of the engine.
17. Remove the front chainguard securing bolt and loosen the rear mounting bolt. Pull the chainguard back several inches to get it out of the way.
18. Remove the four bolts and one nut securing the left and right rear engine-mounting plates. Remove the plates.
19. Remove the nuts and washers from one side of the front upper and lower mounting plates.
20. Remove both right-side rocker boxes.
21. Remove the left lower bolts securing the rear frame to the front frame.
22. Pull out the front upper and lower mounting studs, then lift the engine out the left side of the frame. A helper at this point will greatly reduce the possibility of dropping the engine.

Installation is basically a reversal of the removal procedure. To make sure the wiring harness is properly connected, refer to the appropriate wiring diagram.

TR7V, T140V

1. Shut off the fuel taps, and disconnect the fuel lines. Remove the rubber cap from the top, center, of the gas tank, and remove the sleeve nut below. Take the tank off the frame.
2. Detach the torque stay from the engine by removing the two nuts securing the stay to the cylinder head and removing the bolt and nut from the frame.
3. Disconnect the tachometer cable at the engine.
4. Remove the header pipes and mufflers.
5. Disconnect the oil pressure switch at the timing cover, the clutch cable at the engine, the contact breaker, coil, and alternator leads.
6. Remove the carburetor(s) from the manifold(s) and pull away from the air cleaner.
7. Drain the oil from the frame backbone oil reservoir by means of the drain plug at the very bottom of the reservoir.
8. Disconnect the oil feed line from the bottom of the reservoir, and the oil return line at the top. Disconnect the rocker feed line at the top of the reservoir.
9. Drain the oil from the gearbox and the primary chaincase. Drain the crankcase sump.
10. Disconnect the crankcase breather hoses at the left, rear of the crankcase by loosening the hose clamp screws.
11. Remove the chainguard by removing the securing bolt and loosening the left side bottom shock absorber bolt. Pull the chainguard out of the back of the bike.
12. Remove the drive chain masterlink and disengage the chain from the gearbox sprocket.
13. Remove both footpegs.
14. Remove the two rear engine mounting plates each of which are secured by five nuts and bolts. Remove the bottom and front engine mounting studs. Note the location of the spacers. For both studs, the wide spacer is installed on the right side of the motorcycle.
15. Remove the engine from the left side of the frame.



Installation is essentially the reverse of the removal procedure. Refer to the wiring diagrams in the "Electrical Systems" section to insure that all connections are correct. Refer to "Tune-Up and Maintenance" for the proper grades and quantities of oil.

TOP END

Removal

650 TWINS

1. Remove the fuel tank.
2. Disconnect the battery terminal leads.
3. Disconnect and remove the secondary ignition coils, taking care not to damage the alloy cases.
4. Remove the front and rear torque stays.
5. Disconnect the rocker oil feed line, taking care not to bend it excessively.
6. Remove the rocker inspection caps.
7. Remove the three nuts from the securing studs on the underside of the exhaust rocker box.
8. Remove the exhaust rocker box

Exhaust rocker box securing nuts (650, 750 Twin)

outer securing bolts and the central cylinder-head bolts.

9. Remove the intake rocker box in the same manner, noting that the outer securing bolts may have to be loosened only a little at a time because of clearance difficulties.

10. Make sure to collect the six plain washers that fit underneath the securing nuts. They often stick to the cylinder-head flanges.

11. Withdraw and lay out the pushrods so that they can be installed in their original position.

12. Remove the carburetor(s) and the intake manifold.

13. Remove the exhaust header pipes.

14. Loosen the cylinder head nuts, a little at a time, in a cross pattern. Lift off the cylinder head.

15. Remove the pushrod cover tubes and rubber O-ring seals.

16. Check the tappet guide blocks for sharp edges that could cut into the pushrod O-ring seals. Smooth out any of these sharp edges or rough areas with a fine grade emery cloth.

17. Remove the copper cylinder-head gasket.

18. Wedge a piece of rubber between the intake and exhaust tappets to prevent them from falling into the crankcase when the cylinder is removed.

19. Rotate the engine until both pistons are at top dead center, then remove the cylinder block attaching nuts at the base of the block.

20. Carefully lift up the cylinder block and, as soon as there is enough room, stuff some clean lint-free rags into the crankcase openings. At this time it is also advisable to fit rubber protectors (or a suitable substitute) over the cylinder base studs.

21. Remove the cylinder base gasket and make sure the two locating dowels are in position on the crankcase.

22. Remove the tappets from the cylinder block and mark them for reassembly.

23. Invert the cylinder head on a bench, remove the locking bolts, then drive out the tappet guide blocks with a suitable drift. Make sure the intake and exhaust guide blocks are marked for reassembly, as the exhaust block has drilled oilways and the intake block does not.

TR7V, T140V

1. Remove the fuel tank after shutting off the petcocks and disconnecting the fuel lines. Remove the carburetor(s) from the head.

2. Disconnect the wires from the battery terminals. Remove the exhaust pipes and mufflers.

3. Disconnect the rocker feed line by removing the domed nut on each rocker spindle.

4. Remove the torque stay by removing the nut at each rocker box. Remove the torque stay bolt and nut on the frame.

5. Remove the rocker box inspection covers. Also remove the three nuts from the studs beneath each rocker box. Account for the washer on each of the studs.

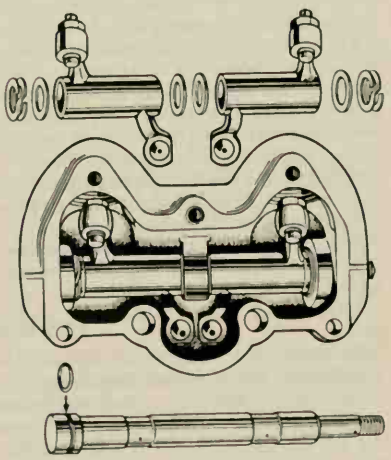
6. Remove the securing bolts on the opposite side of each rocker box, and finally the two larger securing nuts on top. Remove the rocker boxes from the head.

7. Remove the pushrods and place them in a safe place.

8. There are ten cylinder head nuts and bolts. Loosen each one a single turn at a time until they can be turned easily, then remove them. Lift off the cylinder head.

9. New O-rings must be used on the ends of the pushrod cover tubes. New rocker box gaskets should also be used. Be sure that the rocker box mating surfaces are in good condition before refitting.

Rocker Boxes



DISASSEMBLY

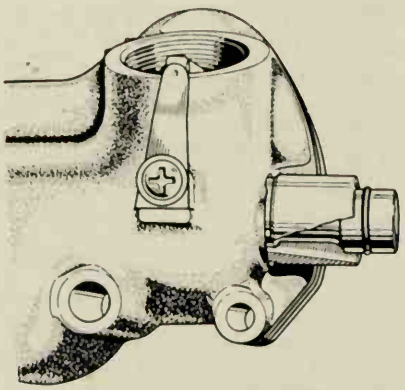
1. Carefully drive out the rocker spindle, using a soft metal drift.

2. Remove the rocker arms and washers.

3. Remove the rocker oil seals.

4. If the rocker ball pins require replacement, drive them out with a suitable drift, then press in the new ones with the drilled flat toward the rocker spindle.

Rocker box assembly (650, 750 Twin)



ASSEMBLY

1. Assemble the rocker boxes using Triumph seal compressor D2221 and a 7/16 x 6 in. bolt with one end ground to a taper.

2. Apply grease to two of the plain washers and position them on either side of the center spindle bearing boss.

3. Position the left rocker arm and insert the alignment bolt, then install the outer plain and spring washers.

4. Position the right rocker arm in the same manner.

Installing the rocker arm spindle

5. Install a new oil seal on the spindle, then coat the whole spindle with oil.

6. Slide the spindle into seal compressor no. D2221 (or a suitable replacement) and through the rocker box, pushing the alignment bolt out the other end. The final positioning of the spindle may require a few taps with a hammer and soft metal drift.

Valves and Valve Springs

REMOVAL

1. Compress the valve springs with the spring compressor and remove the split retainers with a narrow, straight-slot screwdriver.

2. Remove each valve and spring, making certain they are marked and matched for reassembly.

NOTE: *The intake and exhaust valves are marked "IN" and "EX," respectively.*

INSTALLATION

1. Assemble the inner and outer springs with the top and bottom cups over the valve guide.

2. Lubricate the valve stem with a little graphite oil, then slide the valve into position.

3. Compress the spring and install the two retainer halves in the exposed groove of the valve stem.

Valve Guides

Triumph engines are equipped with replaceable bronze valve guides. To remove an old guide, use Triumph special tool 61-6013 or fabricate one to the dimensions given. This is a mild steel bar about 5 in. long and 0.5 in. diameter with a 1 in. section at one end machined to 5/16 in. When installing the new guide, first lightly grease the guide then press or drive it into place, using the special tool. When new valve guides have been installed, it will be necessary to recut the valve seats and grind in the valves.

NOTE: *The intake and exhaust valve guides are almost identical in appearance, except in length. The shorter guides are for the intake valves and the longer guides are for the exhaust valves.*

Tappets and Guide Blocks

The only noticeable tappet wear is in the center of the Stellite tip. An indentation greater than 3/32 in. indicates that the tappet should be replaced.

It is not necessary to remove the guide blocks to check wear. Simply rock the tappets in their respective guide block bores and note the amount of lateral free-play; there should be little or no movement.

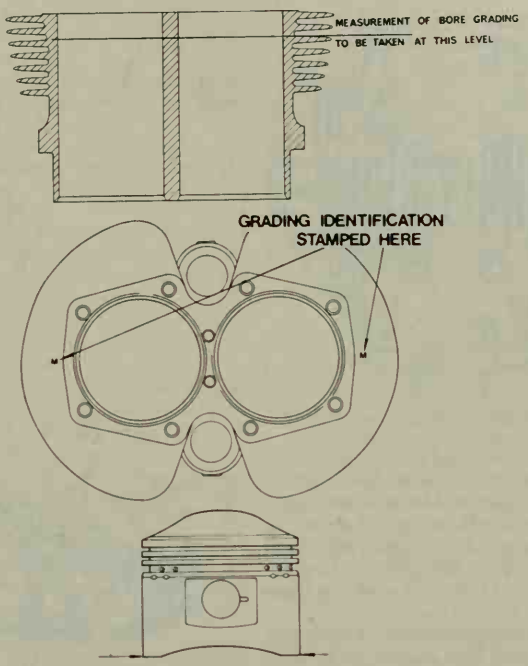
Cylinder Barrel

If there is a difference of 0.13 mm (0.005 in.) between any of the bore measurements, the cylinder should be re-bored.

Pistons

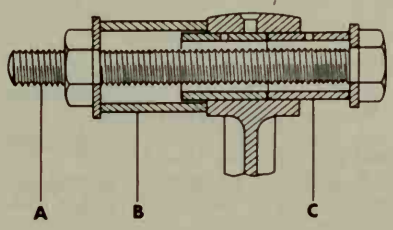
1. Make sure the crankcase opening edges are covered with lint-free rags to protect the aluminum alloy connecting rod from being damaged.
2. Remove the inner and outer piston pin retaining circlips, then attach a piston pin removal tool and press out the pin.
3. Lay out and mark the pistons, pins, and retaining circlips for reassembly.
4. Remove the piston rings one at a time by lifting an end of the ring out of its groove and holding a thin piece of metal between it and the piston. Slide the piece of metal around the circumference of the piston while at the same time gently lifting the raised part of the ring upwards.
5. Replacement pistons (650) are available in three or four oversizes. These sizes and the corresponding recommended cylinder bore sizes are given in a chart at the end of this section.

TR7V and T140V pistons are available in four oversizes in increments of 0.010 in. Also note that the cylinders and pistons for these models are paired up according to a three-step grading system when the engine is assembled at the factory. There are three sizes "L" (Low), "M" (Medium), and "H" (High).



Refer to the accompanying illustrations for cylinder bore and piston skirt measurement points. Then refer to the "Suitable Re-bore Sizes" chart at the end of this section.

6. Install the piston rings one at a time over the top of the piston. Note that the two compression rings are marked "TOP" to ensure correct assembly position. This mark must face upwards when the rings are fitted.
7. Position the piston on the connecting rod.
8. Install one new retaining circlip as a stop, then press the piston pin into position and install another new circlip on the other side.

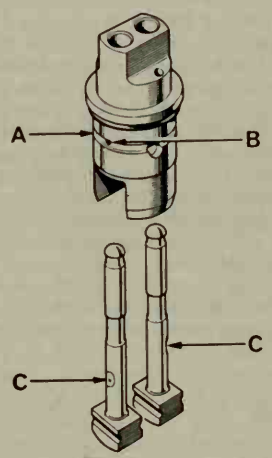


NOTE: *If there is no alternative and the piston pin must be driven into its bore, it is advisable to heat the piston to 100°* C prior to assembly.

Piston Pin and Small End Bushing

Inspect the piston pin for center "step wear," scoring, or burring, then slide it into the small-end connecting rod bushing, and make certain that there is no lateral free-play. If there is, replace the bushing in the following manner:

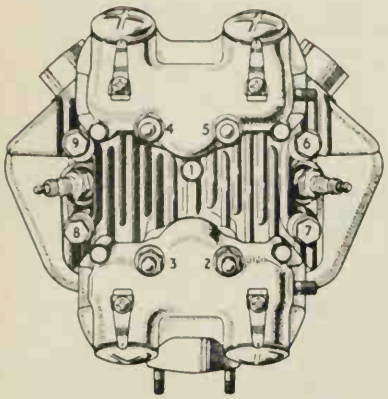
750 Twin piston and cylinder wear measurement points and cylinder grading marks



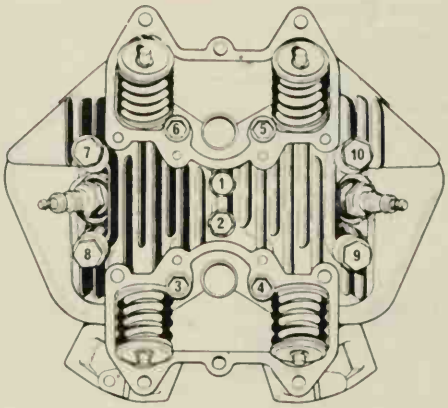
Piston pin bushing replacement: A, bolt; B, tubing collar; C, new bushing

1. Find a threaded bolt approximately 4 in. in length and a piece of tubing 1¼ in. long with an inside diameter of ⅞ in.
2. Place a suitable washer and the new bushing on the bolt, then insert the end of the bolt through the old bushing.
3. Place the piece of tubing over the end of the bolt and screw the nut on finger-tight.
4. Centralize the new bushing and align the oil drillway with that in the old bushing.
5. Now tighten the nut on the bolt and

ASSEMBLY



1. Position new guide block O-ring seals at the base of the cylinder block.
2. Lightly grease the outside surface of the exhaust guide block, then carefully align the guide block and cylinder locating holes and drive the block into position with Triumph special tool no. 61-6008 or a suitable drift.
3. Repeat the above step for the intake guide block, then install the locking bolts.
4. After installing the guide blocks, make sure that the exhaust guide block oil drillways are free from obstruction.
5. Install the tappets in the guide blocks as shown in the accompanying illustration, after thoroughly lubricating



Tappet and guide block (A) oil passage (B, C) alignment

them with oil. Wedge them into position.

6. Install the cylinder base gasket, making certain that the gasket does not obscure the oil feed drillway in the crankcase.
7. Fit ring compressors over the pistons, then carefully slide the cylinder down over the pistons. Remove the ring compressors as soon as the rings are positioned within the cylinder. Continue lowering the cylinder block and then remove the rags in the crankcase openings as late as possible.
8. Install the cylinder base attaching nuts.
9. Replace or anneal the cylinder head gasket.
10. Clean the mating cylinder head and cylinder surfaces, then grease the gasket and position it on the cylinder.
11. Coat the tappet guide blocks with grease and position the pushrod cover

Cylinder head bolt tightening order (650)

Cylinder head bolt tightening order (750 Twin)

tubes with new O-ring seals.

12. Position the cylinder head and install the head nuts and bolts finger-tight.

13. Place a small amount of grease in the bottom cup of each pushrod, then locate the intake pushrods in their respective bores. This will have to be done by "feel."

14. When the pushrods are properly positioned, turn the engine over until both intake pushrods are level and at the bottom of their travel.

15. Install the intake rocker box.

16. Repeat the above procedure for the exhaust rocker box, noting that the central cylinder-head bolts should be tightened to torque specifications before tightening the underside securing nuts.

17. Turn the engine over several times to make sure the valves are operating properly, then reinstall the torque stays and secondary ignition coils.

18. Connect the rocker oil feed line, using either new copper washers or annealed, used ones.

19. The remainder of the assembly procedure is a reversal of the disassembly instructions. Adjust valve tappet clearances.

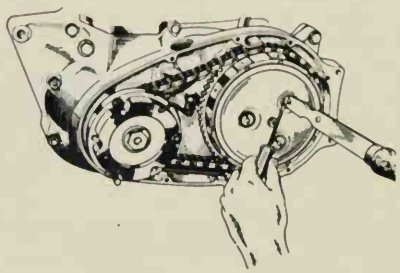
Clutch

Service procedures are basically the same for the 650 and 750cc twins, except that the larger models have a triplex primary drive chain in place of the duplex chain found on the 650.

DISASSEMBLY

1. Remove the left exhaust header pipe.

2. Loosen the rear brake adjustment until the pedal drops clear of the primary cover.



3. Remove the left footrest.

4. Drain the oil from the chaincase, then remove the chain tension adjuster.

5. Remove the ten, recessed, cover-securing screws and withdraw the cover and paper gasket.

6. Remove the chain tensioner assembly.

7. The clutch pressure plate is held in place by three, slotted adjuster nuts. To remove these nuts, slide a knife or screwdriver blade under the nut and loosen it with Triumph tool no. D364 (supplied with tool kit) or a suitable substitute.

Removing the clutch nuts

NOTE: *The nuts are fitted with locking tabs which may be sheared off by removal. If so, replace them.*

8. Remove the clutch springs, cups, and pressure plate assembly.

9. The clutch plates can be removed with the use of two, narrow, hooked tools made of 1/32 in. wire.

INSPECTION

1. If the thickness of the discs is 0.030 in. (0.76 mm), or more, less than specified, they should be replaced.

2. Check the fit of the plate on the shock absorber unit. There should be little radial clearance.

3. Measure the clutch spring length and compare with specifications. If a spring has shortened by 0.10 in. (2.5 mm) or more, replace the whole set.

ASSEMBLY

1. Install the clutch plates and discs, keeping in mind that the innermost position must be occupied by a bonded plate.

2. Install the cups, pressure plate, springs, and slotted adjuster nuts.

3. True the clutch pressure plate by first tightening the pressure-plate, slotted adjuster nuts until they are even with the clutch pins, and then by kicking with engine over and observing the rotation of the plate, and then making any necessary adjustment until the plate turns evenly. If the plate wobbles even slightly, it must be corrected.

Primary Drive and Clutch Hub

DISASSEMBLY

1. Remove the primary cover as previously described.

2. Remove the clutch assembly as previously described.

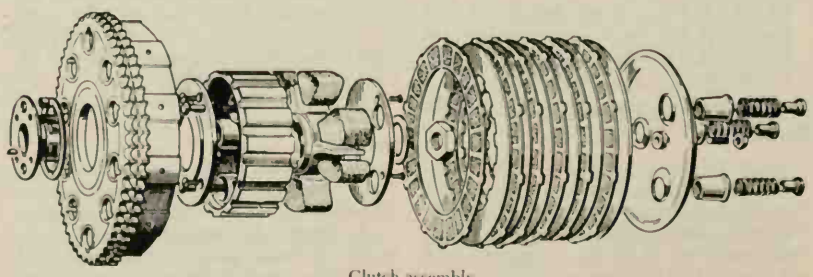
3. Disconnect the alternator stator leads at their snap connectors under the engine.

4. Remove the three, stator securing nuts and withdraw the stator from over its mounting studs. Unscrew the sleeve nut and then the lead can easily be removed.

5. To remove the rotor, bend back the tab washer, and remove the locknut.

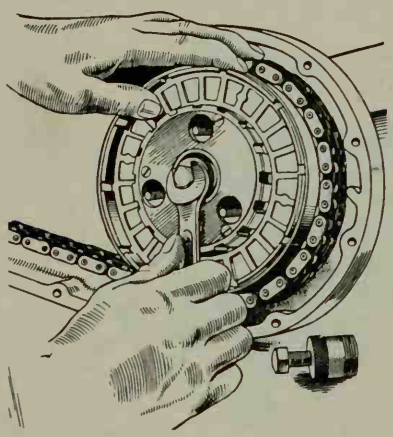
6. Remove the rotor key and distance piece.

7. Remove the clutch hub securing nut and cup.



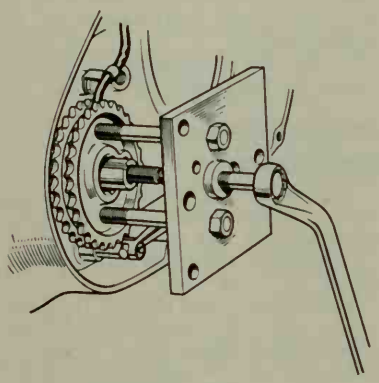
NOTE: *Machines prior to serial no. H49833 have a tab washer and a different cup washer, rather than the self-locking securing nut.*

8. Screw the body of extractor no. Z13 into the clutch hub until it bottoms, then tighten the center bolt until the hub is released.



9. Assemble extractor no. Z151 and D662/3 on the engine sprocket and tighten its center bolt until the engine sprocket is released.

10. Withdraw the engine sprocket, clutch hub, and primary chain together.



11. Remove the transmission main-

Clutch assembly

shaft key and check the oil seal for leakage.

INSPECTION

1. Inspect the clutch shock absorber for worn rubbers or punctures. They can be removed by prying them out, small rubbers first. Replace as necessary. When reassembling, apply thread-locking compound to the cover-plate securing screws.

2. First thoroughly clean the primary chain then check it for wear by scribing two marks on a flat surface 12 in. apart, and centering two pivot pins at the scribe marks. Fully compressed, the chain link pivot should line up with the marks; fully stretched, it should not extend more than ¼ in. beyond the marks.

3. Check the fit between the shock absorber spider and the clutch hub splines. The spider should be a push fit on the clutch hub, with no radial movement.

4. Check the fit of the engine sprocket on the crankshaft in the same manner. There should be no radial movement.

5. Check the clutch hub bearing diameter, rollers, and clutch sprocket bearing. Replace any bearing rollers that are pitted or worn. See specifications.

6. Make sure the shock absorber spider is a good fit in the inner and outer retaining plates, and that the arms have not excessively scored the inner surface of the retaining plates.

ASSEMBLY

1. Grease the clutch hub and install the thrust washer and twenty of the correct rollers. Do not use ¼ in. x ¼ in. rollers!

2. Position the hub and press the shock absorber, complete with the three threaded pins, on the hub.

3. Install a new tapered distance collar behind the engine sprocket, with the taper toward the crankshaft main bearing and oil seal.

4. Install the transmission mainshaft key and tap the clutch hub onto its taper.

5. Lubricate the primary chain and lay it over the clutch sprocket.

6. Wrap the chain around the engine sprocket, then position the sprocket on the crankshaft.

7. Place clutch-locking tool Z13 in the clutch plate housing, then install the cup washer and self-locking nut. Torque the nut to specifications.

NOTE: *On machines before serial no. H49833, install the tab washer with the long tab in the hole in the shock absorber spider, install the securing nut and bend a tab to lock the nut.*

8. Install the alternator rotor, making sure that the key or locating peg is correctly positioned.

9. Install the alternator stator. Put a 0.008 in. (0.2 mm) feeler gauge between each stator pole and the rotor. Turn over the engine to make sure that the rotor and stator do not touch.

10. The remainder of the assembly procedure is a reversal of the disassembly instructions.

Transmission Countershaft Sprocket

REMOVAL AND INSTALLATION

1. Disassemble the clutch and primary drive as previously described. Remove the sprocket cover.

2. Bend back the tab washer and, while holding the rear brake, remove the sprocket securing nut.

3. Slide off the final drive chain and remove the countershaft sprocket.

4. Make sure the oil seal is in good condition, then lubricate the ground boss of the new sprocket and position it on the transmission mainshaft.

5. Replace the tab washer, screw on the securing nut finger-tight, then, with the chain in place, tighten the nut to torque specifications.

6. Oil the bushing that protrudes from the mainshaft high gear and install the sprocket cover with a new paper gasket.

7. The remainder of installation is a reversal of the removal procedure.

Shifter, Kick-Starter, and Clutch Operating Mechanisms

DISASSEMBLY

1. Remove the right exhaust header pipe.

2. Remove the right footrest.

3. Loosen the clutch cable adjustment at the handlebar lever, then disconnect the cable end from the operating lever in the gearbox outer cover.

4. Drain the gearbox oil into a suitable container.

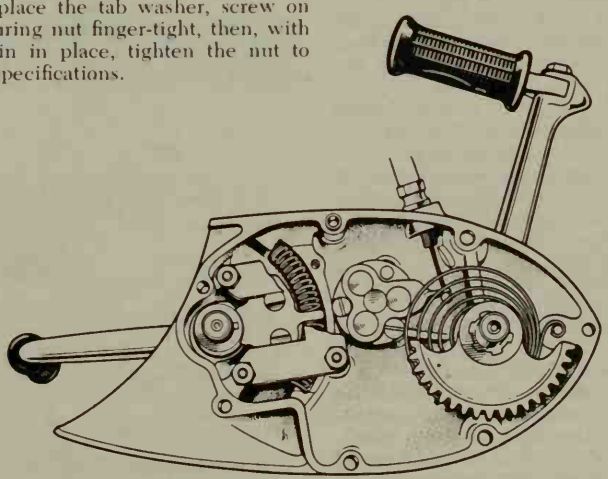
5. Put the transmission in high gear.

6. Remove the top and bottom nuts and recessed screws that secure the gearbox outer cover. Depress the kick-start lever slightly and tap the cover lightly until it is free.

7. Loosen the kick-starter cotter pin nut a few turns, then drive out the cotter pin.

8. Slide the lever off the shaft and remove the kick-starter quadrant and spring assembly.

9. Apply the rear brake, bend back the tab washer, and remove the kick-starter ratchet pinion securing nut.



10. Remove the pinion, ratchet, spring, and sleeve.

11. If the kick-starter quadrant is to be replaced, drive out the spindle with a suitable drift and hammer. Install the new spindle so that the kick-starter lever location flat is correctly positioned with respect to the quadrant.

12. Remove the shifter foot pedal from the shaft.

13. Remove the guide plate, plunger quadrant, and curved return springs.

14. Remove the two screws that secure the clutch operating mechanism. Remove the securing cotter pin and disassemble the mechanism.

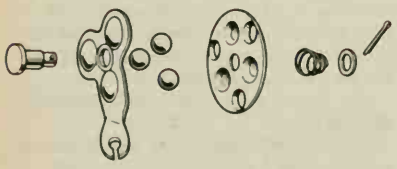
Gearbox outer cover assembled

INSPECTION

Kick-Starter

Inspect the ratchet teeth for burrs, chips, or rounded edges. Make sure the ratchet spring is in good condition and that the thin-walled steel bushing is a clearance fit in the kick-start pinoin. Examine the kick-starter stop peg to make certain it is firmly pressed into the inner cover and is not distorted in any way.

If it is necessary to replace the kick-start spindle bushing, heat the cover to 100° C, then drive out the bushing with a suitable, shouldered drift. Drive in the new bushing while the cover is still hot.



Shifter

If the shifter spindle bushing requires replacement (outer cover), heat the cover surrounding the bushing to 100° C and drive the bushing out with a suitable, shouldered drift. Drive in the new bushing before the cover has a chance to cool.

The inner cover spindle bushing will probably never need replacement, since it suffers an insignificant amount of wear. If it does require replacement, however, it will be necessary to tap the bushing, heat the cover, install an appropriate bolt and then drive it out.

Clutch Operating Mechanism

The clutch operating mechanism is constantly immersed in oil, so wear should be negligible. Inspect the balls for pitting, etc., and make sure they operate smoothly in the plates.

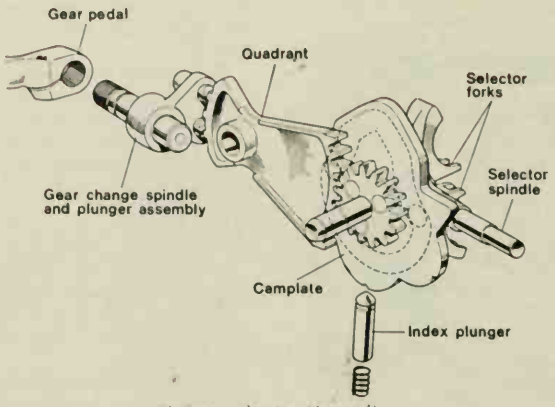
Clutch operating mechanism

ASSEMBLY

1. Assemble and install the clutch operating mechanism, using the accompanying illustration for reference.

2. Install a new rubber O-ring on the shifter spindle and install the spindle in the outer cover bushing, using a few drops of oil to aid installation.

3. Install the two quadrant-return springs, making certain they are correctly located over the step in the cover.



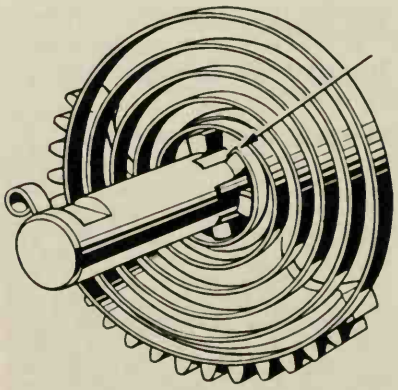
NOTE: *To facilitate connecting of the springs, first install the shifter pedal and clamp it in place, thereby allowing the quadrant to turn and the springs to be compressed.*

4. Install the retainer plate with its four securing nuts and lock washers.

5. Install the plungers and springs, taking care that they don't go springing off somewhere during assembly.

6. Install the kick-starter thin-walled steel sleeve, spring pinion, and ratchet.

7. Install the tab washer and the retaining nut, then torque the nut to specifications and lock it by bending up the washer tab. Do not overtorque the nut as it may cause the thin sleeve to collapse.



Shifter mechanism (4-speed)

8. Connect the return spring to the kick-starter quadrant as shown in the accompanying illustration.

9. Install the spindle in the kick-starter bushing and connect the return spring to the anchor peg at the rear of the cover.

10. Install the oil seal over the spindle and assemble the kick-starter lever and securing cotter pin.

11. Clean the outer cover joining surface and apply fresh sealing compound. Make sure the two locating dowels are in position.

Kickstarter return spring installed

12. Move the kick-starter lever halfway through its stroke, then fit the outer cover on the gearbox.

13. Before installing the remaining parts, make sure the kick-start lever is fully operational and returns to its upright position.

14. The rest of the assembly is a reverse of the disassembly procedure.

Gearbox Service

DISASSEMBLY

1. Remove the gearbox outer cover as previously described, leaving the gearbox engaged in high gear.

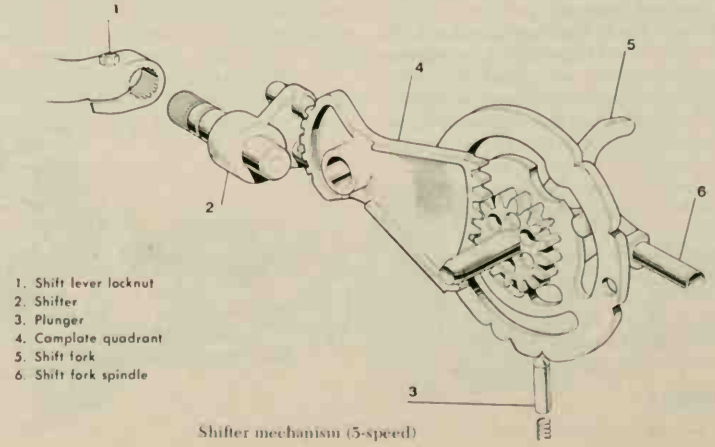
2. Remove the right rear engine plate.

3. Bend back the tabs on the lockwasher, apply the rear brake, and unscrew the kick-starter pinion ratchet retaining nut from the gearbox mainshaft.

4. Remove the clutch and primary drive as previously described. Don't forget to remove the mainshaft key.

Refer to the appropriate procedures, below, for 4-speed or 5-speed service.

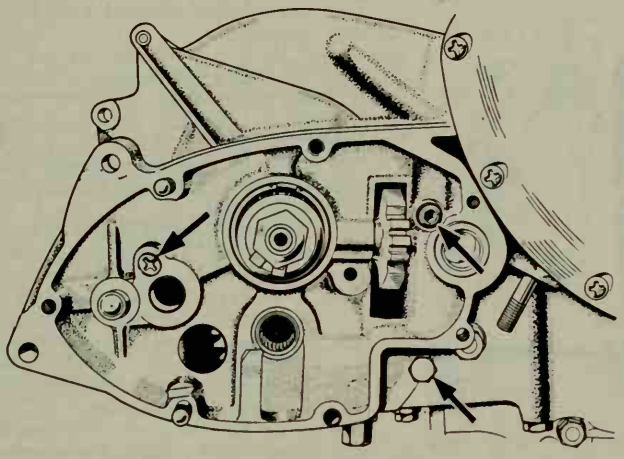
4-Speed:



5. Remove the large dome nut from under the gearbox and withdraw the camplate indexing plunger and spring.

6. Remove the allen screw, phillips screw, and bolt that secure the inner gearbox cover. Tap the cover with a mallet until it is free.

7. Remove the selector fork spindle and then withdraw the mainshaft assembly.



8. Remove the layshaft and remaining gears.

9. Remove the camplate and spindle

1. Shift lever locknut
2. Shifter
3. Plunger
4. Camplate quadrant
5. Shift fork
6. Shift fork spindle

assembly and then remove the two bronze thrust washers located over the needle roller bearings.

10. Remove the circular countershaft sprocket cover from the primary inner cover. Remove the sprocket securing nut.

11. Drive the mainshaft high gear through into the gearbox with a suitable drift. Replace the oil seal.

5-Speed:

5. Remove the allen bolt, phillips screw and bolt and remove the gearbox inner cover, tapping it outward with a softfaced mallet if necessary.

6. Remove the engaging dog pinion from the countershaft. Remove the circlip from the countershaft.

7. Pull out the shift fork rod, then remove the countershaft first gear along with the shift fork.

8. Remove the countershaft second gear, then remove the mainshaft with its first, second, and third gears in position.

9. Take out the mainshaft fourth gear and the countershaft third gear together with the two shift forks.

10. Remove the countershaft fourth and fifth gears.

11. Remove the two thrust washers over the countershaft needle bearings: one on each countershaft bearing.

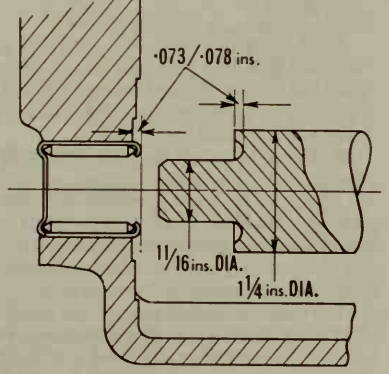
12. To remove the mainshaft high gear, remove the plate from the inside primary chaincase at the back of the clutch. Bend back the locking plate, and unscrew the sprocket nut. Drive the high gear into the box with a soft-faced mallet or drift.

13. Remove the camplate plunger nut at the bottom of the transmission case, and take out the spring and plunger. Remove the camplate from the gearbox.

14. Carefully inspect the condition of the mainshaft oil seal after removing the gearbox sprocket.

MAINSHAFT BEARINGS

The mainshaft bearings are press-fit into their housings and are retained by spring circlips to prevent sideways motion due to end thrust. To remove the right bearing, remove the circlip, heat the cover to 100° C, and drive the bearing out with a suitable, shouldered drift. Install the new bearing while the cover is still hot. Reinstall the circlip.

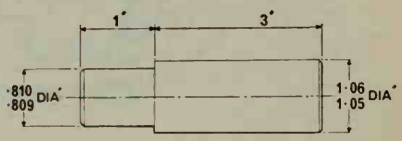


To remove the high gear bearing on the left side, pry out the large oil seal, then remove the retaining circlip. Heat the case around the bearing to 100° C, then drive the bearing out with tool no. Z15 or a suitable, shouldered drift. Install the new bearing while the base is still hot. Install the circlip and press in a new seal.

To replace the high gear bushing, (4-speed transmission) press it out with a suitable, shouldered drift. This drift can be fabricated by machining ¾ in. on one end of a ⅞ in. x 5 in. bar to $^{13}/_{16}$ in. diameter. The bushing must be pressed out from the tooth side of the gear. Install the new bushing in the same manner, making sure the oil groove in the bushing is on the tooth side of the gear. Ream the bushing to the size given in specifications and make sure any filings are removed from the case before reassembly.

LAYSHAFT BEARINGS

Remove the right bearing by heating the cover to 100° C and pressing or driving it out with a drift similar to the one shown in the accompanying illustration. Press in the new bearing, while the cover is still hot, from the inside of the cover until 0.073-0.078 in. of the bearing protrudes, as shown in the accompanying illustration.

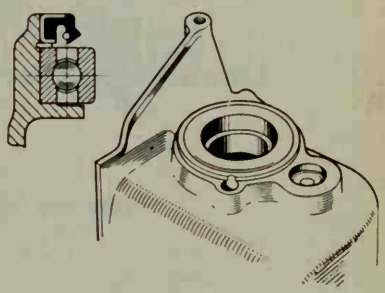


Remove the left bearing by heating the cover housing to 100° C and driving it through into the gearbox with a suitable drift inserted through the countershaft sprocket aperture. Press the new bearing into place while the cover is hot. It must protrude 0.073-0.078 in. inside the gearbox.

Layshaft bearing installation

MAINSHAFT HIGH GEAR BEARINGS (5 SPEED)

The mainshaft high gear is fitted with two caged needle bearings (one in each end). Press them out and in together with a drift of the dimensions shown in the illustration.



High gear needle bearing drift dimensions

ASSEMBLY

4-Speed

1. Drive a new oil seal up to the main bearing with the lip and spring toward the bearing.

2. Press the high gear into the bearing.

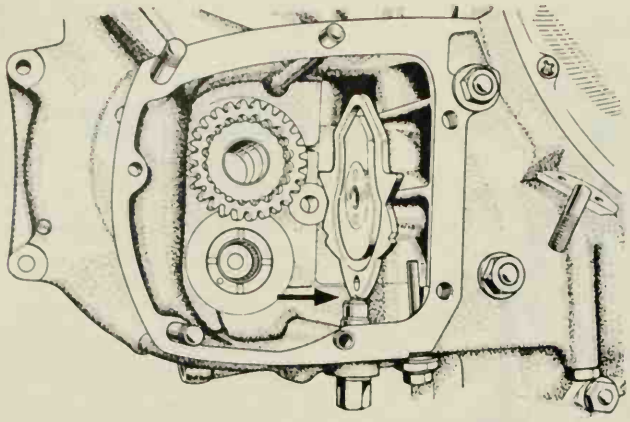
Mainshaft oil seal (4-speed)

3. Lubricate the ground taper of the countershaft sprocket with oil and slide it on to the high gear. Screw on the securing nut finger-tight.

4. Connect the final drive chain over the sprocket, then tighten the securing nut to specifications with tool no. Z63 or a suitable substitute.

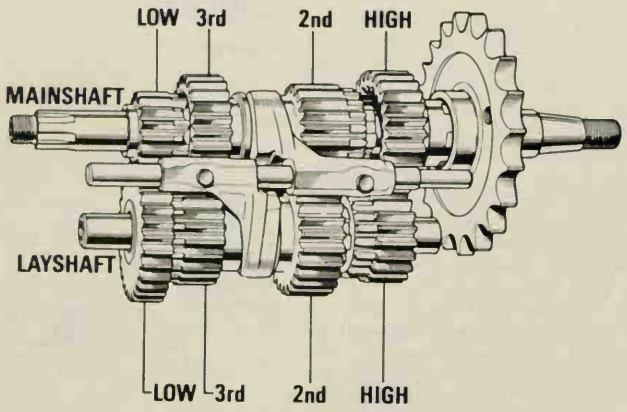
5. Lubricate the extended nose of the high gear with oil, then reinstall the sprocket cover with a new paper gasket.

6. Lubricate the camplate spindle and install it in its housing within the gearbox.



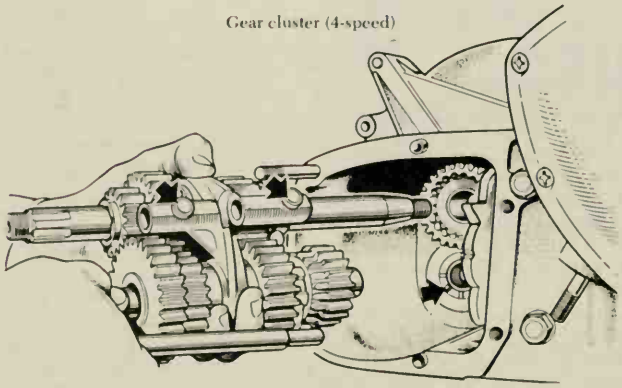
7. Assemble the camplate plunger and spring in the domed retaining nut and screw it into position under the gearbox. Don't forget the fiber washer.

8. Locate the camplate plunger in the notch between second and third gear.



9. Position the thrust washer over the inner needle roller bearing. Coat the washer with grease to hold it in place and note that the grooved surface of the washer should be toward the layshaft.

10. Lubricate the captive mainshaft and layshaft gears, then assemble them in a cluster as shown in the accompanying illustration.



11. Grease the camplate rollers, then position them on the selector forks as shown in the accompanying illustration.

Gearbox assembly with camplate notch between 2d and 3rd gear engaged (4-speed)

Gear cluster (4-speed)

Installing the gearbox components (4-speed)

NOTE: *The selector fork with the smaller radius is for the mainshaft cluster.*

12. Install the mainshaft and layshaft cluster in the gearbox. As the shafts are being located in their respective bearings, the gears should be slid into position and aligned so that the selector fork rollers engage the camplate and the selector forks are approximately aligned.

13. Lubricate the selector fork spindle with oil, then slide it through the forks, shoulder end first, until it is fully situated in the gearbox housing.

14. Make sure the camplate quadrant is moving freely in the inner cover, then position the layshaft thrust washer over the bearing in the inner cover. Hold it in place by smearing it with grease.

15. Thoroughly lubricate all parts in the gearbox with a pressure oil can, then apply fresh sealer to the joining surface of the gearbox. Make sure the two locating dowels are in position.

16. Begin to install the inner cover assembly, and when the joining surfaces are about ¼ in. apart, position the camplate quadrant in the middle point of its travel, and quickly complete the installation. This will align the camplate middle tooth with the mainshaft centerline.

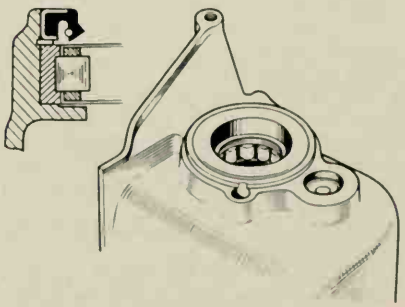
17. Install the gearbox securing screws and nut, then temporarily install the gearbox outer cover assembly and check out the gearbox operation. If there is a problem, chances are the quadrant teeth are not correctly engaged with the camplate pinion.

18. The remainder of the assembly procedure is a reversal of the disassembly instructions.

5-Speed

1. Replace the camplate after lubricating the camplate spindle with some gearbox oil.

2. Refit the mainshaft oil bearing noting that the lip faces the mainshaft bearing. A new oil seal must always be used.



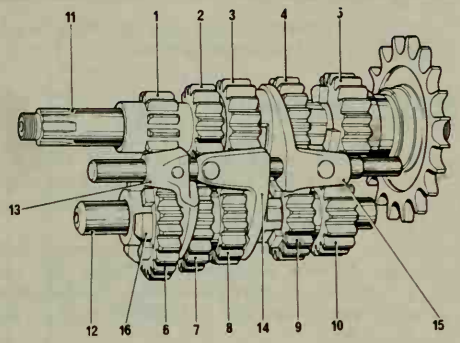
3. Push the mainshaft high gear into the bearing. Put some transmission oil on the tapered boss of the gearbox sprocket and place it on its shaft, in place, then replace the sprocket nut, tightening it by hand for the time being.

4. Run the drive chain over the gearbox sprocket. Apply the rear brake and tighten the sprocket nut as tight as possible.

5. Lubricate the end of the high gear which protrudes into the primary chaincase, and refit the cover plate. A new paper gasket should be used.

6. Replace the thrust washer over the inner needle bearing. The grooved surface of the thrust washer must face the countershaft. The washer may be held in place by smearing the rear surface with a bit of grease.

7. Refer to the accompanying illustration, and set the camplate in the "neutral" position, and refit the cam plunger, spring, and bolt on the bottom of the gearbox.



Gear cluster (5-speed)

8. With gearbox oil, lubricate the needle bearing in the high gear and the countershaft bearing. Place the mainshaft high gear onto the mainshaft. Also refit the shift fork to the mainshaft. Note that the three shift forks are all different, and this one has a large engaging pin and no cutaway on the housing.

9. Insert the mainshaft assembly into the high gear, engaging the pin on the shift fork with the camplate groove. Use onto the mainshaft. Also refit the shift fork to the mainshaft. Note that 10. Replace the countershaft with its two highest gears into the gearbox, engaging these gears with their mainshaft counterparts. Note that none of the sliding gear dogs will be engaged if the transmission is set at neutral.

11. Refit the countershaft third gear and its shift fork. This shift fork has a large engaging pin and a cutaway on the housing. Refit the mainshaft third gear

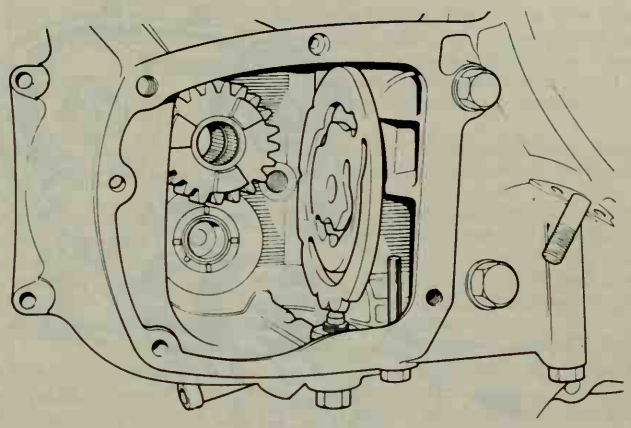
and engage it with the corresponding countershaft gear.

12. Lubricate the countershaft second gear bushing and replace the gear on the countershaft.

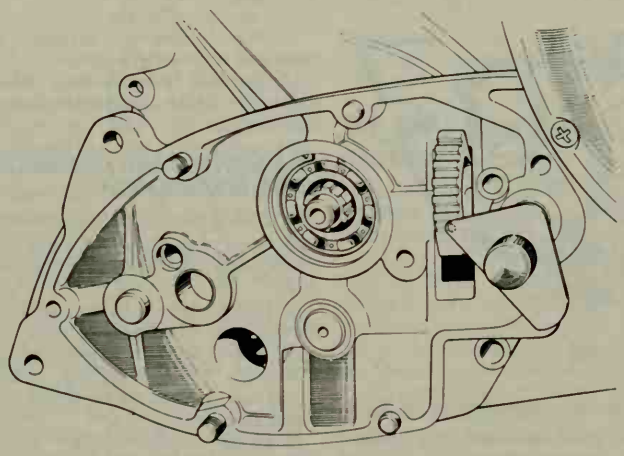
13. Replace the first and second gears onto the mainshaft. Refit the countershaft first gear with its shift fork. Note that this shift fork has the smaller engaging pin.

14. Insert the shift fork rod. Replace the circlip on the end of the countershaft, and replace the engaging dog pinion against the circlip.



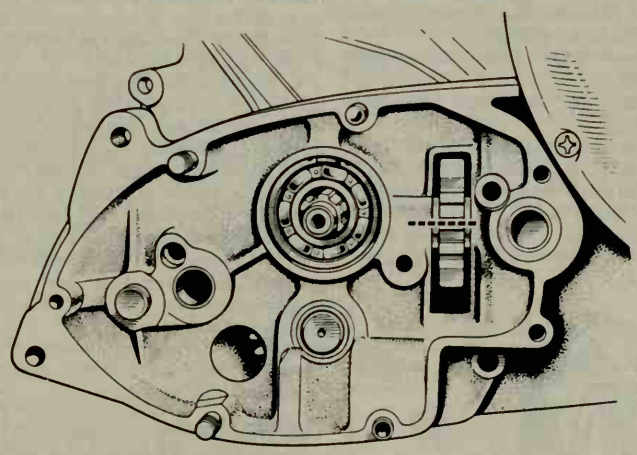
15. Turn the camplate counterclockwise (relative to a rider on the machine), which will place the transmission in first gear. Note that the engaging dog pinion on the countershaft will mesh with the dogs on the countershaft first gear, groove facing the countershaft.

16. Insure that the camplate quadrant operates freely. Replace the thrust washer over the needle bearing for the countershaft in the gearbox cover.



17. Lubricate all moving parts in the gearbox with transmission oil. Apply some gasket compound to the gearbox mating surfaces. Begin refitting the inner cover. When the inner cover is about ¼ in. away from the mating surfaces, position the camplate quadrant as shown using the special tool (60-6128). If not available, line up the top edge of the second tooth on the quadrant with an imaginary horizontal line through the center of the gearshift spindle housing. This housing is at the extreme forward part of the inner cover, and is shown occupied by the special tool in the illustration of the inner cover.

18. Refit the inner cover securing bolt and screws tightening them lightly. Assemble the outer cover and gearshift lever and check that the shifter operates properly. If not, it is probable that the quadrant teeth are not properly engaged with the camplate gear.



19. Assuming that the shifting is working properly, tighten the inner cover securing bolt and screws, and refit the kickstarter assembly, the outer cover, and refill the gearbox and primary chaincase with the correct amounts and grades of oil.

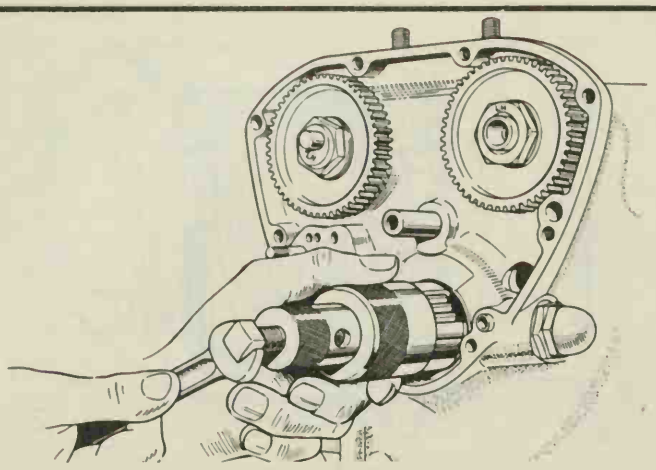
DISASSEMBLY

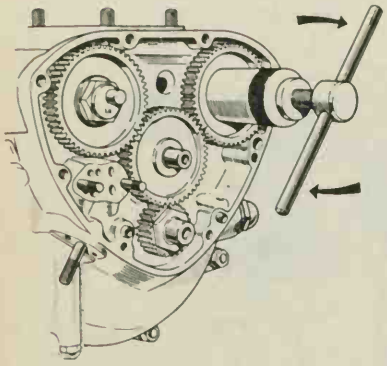
1. Remove the primary chaincase cover and disconnect the alternator leads under the engine.

2. Remove the three screws that secure the alternator stator, and pull the stator off its mounting studs. Do not disconnect the leads at this time.



3. Disassemble the clutch and primary drive as previously described. Remove the stator sleeve and withdraw the stator leads.

4. Remove the gearbox outer cover and dismantle the gearbox.



5. Remove the rocker boxes, cylinder head, cylinder barrel, and pistons.

6. Disconnect the clutch cable and remove the carburetor(s). Remove the timing cover. Note that the screws are of different lengths.

7. Remove the contact breaker cover and the oil pump, then remove the crank-

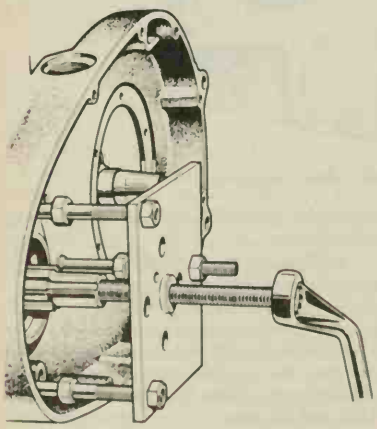
shaft pinion. The camshaft pinions can also be removed at this time.



NOTE: *The camshaft pinion nuts are left-hand threads. The crankshaft nut has a right-hand thread.*

8. Remove what's left of the engine from the frame.

9. Remove the crankcase filter and oil-way plug.

10. Clamp the crankcase firmly in a vise at the bottom mounting lug and remove the three bolts and two screws near the cylinder base.

11. Remove the four remaining studs and the two nuts next to the gearbox housing.

Separating the case halves

12. Attach Triumph extractor no. 61-6064 and separate the cases.

13. Remove the breather valve from within the intake camshaft bushing in the left case.

CRANKSHAFT AND CONNECTING RODS DISASSEMBLY

1. Clamp the crankshaft assembly in a soft-jawed vise and place a rag over any sharp edges to protect the connecting rods.

2. Unscrew the cap retainer nuts a little at a time to avoid distortion, then remove the caps and connecting rods.

NOTE: *The connecting rods, caps, and nut are center-punched to facilitate reassembly.*

3. Using a large impact driver, unscrew the oil tube retainer plug from the right end of the big-end journal. If necessary, drill a hole ⅛ in. deep and ⅛ in. in diameter to eliminate the locking effect of the plug center punch.

4. Remove the flywheel bolt next to the big-end journal, then pull out the oil tube with a hooked piece of stiff wire through the flywheel bolt location hole.

5. Thoroughly clean all parts in kerosine or a cleaning solvent, then blow them dry with compressed air. Make sure the oil drillways are blown clear.

6. To remove the flywheel, unscrew the two remaining bolts and press the crankshaft out of the right-side bearing with a five ton press.

NOTE: *Before removing the flywheel, make certain it is marked for reassembly.*

INSPECTION

Inspect the big-end journals for any signs of scoring, etc., and measure the journal diameter. Compare with specifications. Light score marks can be removed with fine-grade emery cloth, but make sure all metal filings are removed before reassembly. If the scoring is light, new connecting rod shell bearings should be installed; if the scoring is extensive, the journals should be reground to an appropriate undersize.

NOTE: *The replaceable big-end bearing shells are pre-sized to give the correct dimensions. Under no circumstances should they be scraped, or the connecting rod and cap filed to alter the bearing dimensions.*

ASSEMBLY

1. Position the oil tube in the crankshaft, aligning the flywheel bolt holes with those in the crankshaft. Temporarily install one of the flywheel bolts to secure it in position.

2. Apply thread-locking sealant to the oil tube plug and install it in the crankshaft. Center-punch the crankshaft opposite the slot to lock the plug in position.

3. Heat the flywheel to 100° C, then position it over the crankshaft with the center punch mark to the right. Turn the flywheel through 180° to get it over the crankshaft web, then turn it to the correct position relative to the crankshaft and align the bolt holes.

4. Coat the flywheel bolt threads with a thread-locking sealant, then install and torque them to specifications.

5. If a new or reground crankshaft, or a new flywheel was installed, the assembly should be rebalanced.

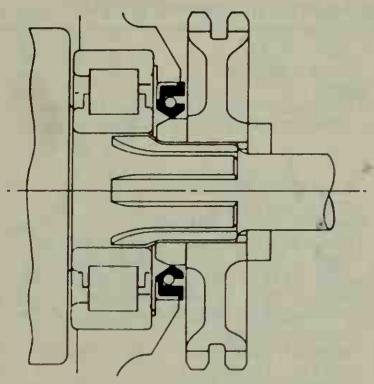
6. Check to make sure all the oil drillways are free from obstruction, then install the connecting rods and caps. Torque the retaining nuts to 28 ft lbs.

7. Last, force oil through the crankshaft, right main-bearing journal drillway until it is expelled at both big-end bearings. This will provide assurance that the drillway is free from obstruction.

CAMSHAFT BUSHINGS

The intake and exhaust camshafts run in bronze bushings.

To remove the bushings in the left case, a tap will be necessary. The ideal size is ⅞ in. diameter x 9 whitworth.



When a good thread has been cut in the bushing, heat the case to 100° C and screw in the appropriate bolt. Grip the bolt in a vise and tap the case with a soft-faced mallet until the bushing is free. The replacement bushings are pre-sized but will require a light reaming to meet specifications. After reaming the new bushings, make sure the crankcase is thoroughly cleaned to remove any metal filings.

To remove the bushings in the right case, heat the area around the bushing to 100° C, then drive it out with a suitable, shouldered drift. Install the new bushing while the case is still hot, making sure the oil drillway holes are aligned.

MAIN BEARINGS

To remove the left main bearing, heat the case to 100° C and drive it out with tool no. Z14. Only the right main bearing spool remains in the case, and is removed by first removing the lock plate, heating the case to 100° C, then driving it out with tool no. Z162 or a suitable, shouldered drift. It is advisable to replace the left bearing oil seal while the engine is apart, even if it appears to be in good condition.

To install the left and right bearings, first make sure that their housings are clean, then heat the cases to 100° C and drive the bearings into position with a

Left main bearing oil seal installation

tubular drift the same size as the bearing outer race. A suitable size would be 2¾ in. diameter x 6 in. long.

After both bearings have been installed, press the oil seal into the left case. This is installed with the spring side facing away from the bearing.

ASSEMBLY

1. Thoroughly clean the mating crankcase halves, giving special attention to the locating dowels. Install the oilway plug.

2. Position the left case on two wooden blocks, lubricate the main bearing and camshaft bushings and then install the breather valve and spring in the intake cam bushing. Assemble both camshafts, making sure the intake cam slot engages the breather valve dog, if fitted.

3. Carefully install the crankshaft assembly, making sure the fit in the bearing is good.

4. Apply fresh joining compound to the mating surfaces, then position the connecting rods in the center and lower the right case over the crankshaft. When the halves are mated, check to make sure the crankshaft and camshafts are not binding. The crankshaft should rotate freely, while the camshafts should offer only slight resistance.

5. The remainder of the assembly procedure is a reversal of the disassembly instructions. Torque all bolts and nuts to specifications.

T150

Engine Removal and Installation

1. Remove the fuel tank.

2. Drain the oil tank and crankcase. Remove the oil cooler.

3. Disconnect the rocker box oil lines, then disconnect the oil supply lines from underneath the rear of the crankcase.

4. Remove the carburetors and exhaust header pipes.

5. Unbolt and remove the right-side footpeg.

6. Unscrew the retaining bolt at the front of the chainguard, remove the lower left-side shock absorber mounting nut, and remove the chainguard.

7. Remove the masterlink and pull the drive chain off the countershaft sprocket.

8. Disconnect the alternator and contact breaker point leads at their connectors. Remove the spark plugs.

9. Turn the cable adjuster at the clutch lever all the way in until the cable is completely slack. Take out the four, clutch, inspection-cover retaining screws and disconnect the clutch cable from the release lever.

10. Disconnect the tachometer cable from the tachometer drive at the front of the crankcase.

11. Pull the engine breather tube off at the rear of the inner primary chaincase.

12. Unscrew the pinch-bolt and pull the brake pedal off its shaft.

13. Unscrew the nut from the kickstart lever shaft and drive out the locating pin by tapping on the end of the threads with a small hammer. Remove the kickstarter lever.

14. Unscrew the five bolts and nuts from the right-side rear engine mount plate. Unscrew the swing arm shaft nut and remove the plate. It is not necessary to remove the left mount plate.

15. Unscrew the nut from the long engine mount bolt underneath the crankcase and drive the bolt out. Note the position of the spacer between the crankcase and frame lug before removing the bolt.

16. Support the engine and remove the engine mount bolt at the front frame down-tube. Raise the engine slightly and remove it from the left side of the frame.

Installation is in reverse order of removal. The following points should be noted:

1. Be sure to reinstall the engine mount spacers and washers in their original positions.

2. When connecting the oil lines underneath the crankcase, the smaller (delivery) oil line is attached to the small, straight, junction pipe, and the larger (scavenge) line is attached to the stepped-down junction pipe.

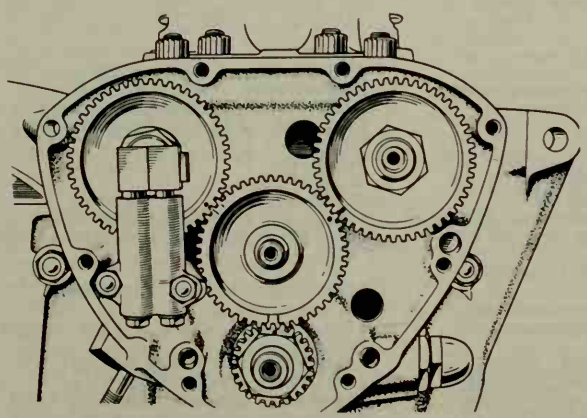
3. Adjust the clutch cable free-play at the handlebar lever after the cable has been reconnected.

4. Adjust the rear brake after the pedal has been installed.

NOTE: *Before starting the engine, ½ pt of oil should be poured into the crankcase. The oil can be added through the timing plug aperture in the right case.*

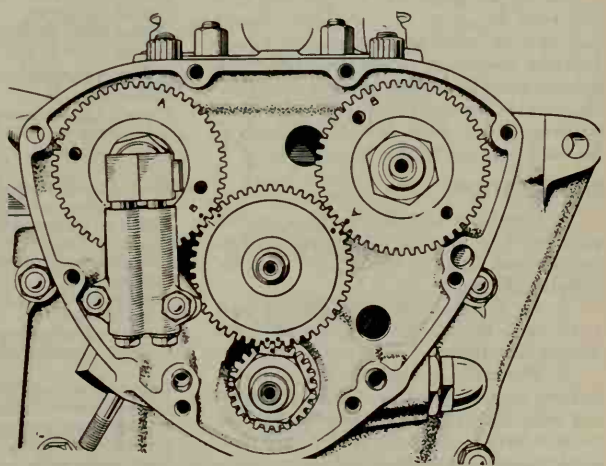
Top End

REMOVAL



The cylinder head and barrel on the Trident can be removed with the engine in the frame. The procedure is as follows:

1. Turn off the fuel taps and disconnect the lines. Remove the metal strip running down the center of the fuel tank (early models) or the rubber plug at the top of the tank (later models). Unscrew the retaining nut and remove the tank.



2. Loosen the oil line clamps at the oil cooler and pull the lines off their connector pipes. Mark the lines and pipes to facilitate correct reassembly. *Do not unscrew the large hexagonal connectors from the cooler.* Unbolt the oil cooler bracket from the frame and remove the cooler. Note that the bracket is insulated from the frame with rubber bushings to protect the cooler from vibration.

3. Disconnect the throttle cable from the linkage at the carburetors and disconnect the choke cable at the handlebar lever. Loosen the carburetor-to-intake manifold clamps and remove the carburetors as a unit.

4. Unscrew the exhaust header pipe

Timing gear mark alignment (650)

Timing gear mark alignment (750 Twin)

nuts at the cylinder head. Disconnect the mufflers from the pipes and remove the header pipe assembly.

5. Unbolt and remove the top engine mount (cylinder head stay).

6. Unscrew the two acorn nuts that secure the rocker oil feed lines to the rocker shafts and tie the pipes out of the way. Remove the access covers and completely loosen the valve adjusters to relieve the head studs of valve spring pressure.

7. Remove the two, small end bolts and three nuts (at the underside of the cylinder head) that secure the rocker boxes to the head. Loosen the head bolts and nuts gradually, in the sequence shown, and then lift off the rocker boxes.

8. Remove the spark plugs, unscrew the remaining cylinder head bolts, and lift the head carefully off the studs. Remove the pushrod tubes and pushrods.

9. To prevent the tappets from falling into the crankcase when removing the barrel, wrap electrical tape around the top of each tappet.

10. Loosen the cylinder-barrel retaining nuts gradually, in the sequence shown, to prevent distortion. Lift the barrel carefully off the crankcase, taking care to support the pistons as they are exposed by the cylinders so that they won't be damaged on the crankcase flange. Mark the tappets so they can be replaced in their original positions. *This is very important.*

11. Remove the piston wrist pin circlips, heat the piston crown, and remove each piston, marking it for location (L,R,C) and mark the front or back for position.

12. To disassemble the rocker mechanism, tap the rocker shafts out from the threaded end. Be sure to install the thrust washers and springs in their correct positions when assemblying.

Cylinders

Maximum allowable wear is 0.005 in.

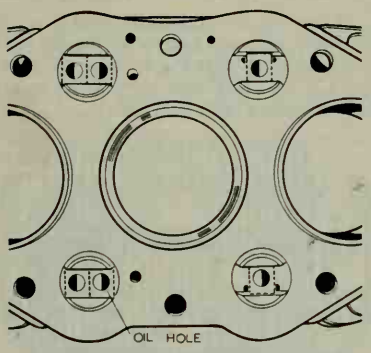
Pistons

These are available in four oversizes, in increments of 0.010 in.

Tappets

The tappet guide blocks, pressed into the base flange of the cylinder, should not normally need replacement. If it does become necessary to replace them, the dowels must be drilled out and the cylinder must be heated before the guides can be pressed out. New dowels will have to be used along with the new guides.

INSTALLATION



1. Carefully install the rings on the pistons. Note that the compression rings are tapered, and the work "top" must be installed facing up.

2. Be sure to coat each moving part with fresh engine oil or assembly lube during installation.

3. Warm the pistons and install them, in their original positions on the connecting rods. Insert the wrist pins before the pistons have a chance to cool. Install *new* circlips and make sure that they are properly seated.

Correct cam follower positions (Trident)

4. Install the tappets in their original positions. Wrap a piece of tape around the top of each tappet stem to prevent it from falling into the crankcase as the cylinder is installed. Make sure that the oil holes in the tappet stems line up with the oil holes in the guide blocks, as shown.

5. Install a new cylinder base gasket on the crankcase flange. Stagger the end gaps of the piston rings 120° apart and oil the rings liberally. Bring the center piston up to top dead center and install a ring compressor. Slide the cylinder down over the piston. Raise the outside pistons as far as possible without accidentally pulling the center piston out of its bore. Install the outer pistons and seat the cylinder against the crankcase. Tighten the cylinder retaining nuts gradually, in the proper sequence, to 20-22 ft lbs.

Pushrod tube assembly (Trident)

6. Remove the tape from the tappets and fit the pushrod tubes over the tappet guides. Make sure that the rubber seals at either end of the tubes are in good condition.

7. Install a new head gasket on the cylinder with the ribs facing down (toward the cylinder). Install the cylinder head carefully over the studs and onto the cylinder. Fit the four outer head bolts loosely. Insert the pushrods onto their tubes. Make sure that the pushrods line up evenly. *This is very important.*

8. Install the rocker boxes on the head using new gaskets. Coat only one side of the gaskets with cement. Make sure that the pushrods are properly seated in the rocker arms.

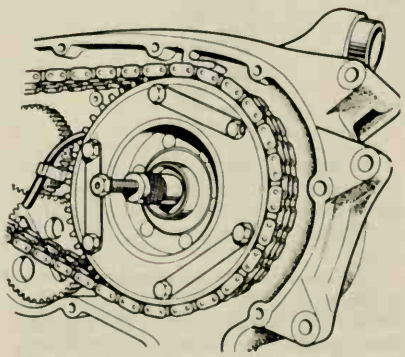
9. Install the remaining eight, cylinder head bolts and tighten all twelve nuts and bolts evenly, in the sequence shown, to 18 ft lbs. Refit the remaining rocker box mounting bolts and nuts.

Cylinder head bolt tightening sequence

10. Reconnect the rocker oil lines using new copper washers. Install the top engine mount and exhaust headerpipes. Install the carburetors on the head and connect the throttle and choke cables. Bolt the oil cooler onto the frame, taking care to install the rubber bushings correctly, and connect the oil lines. Install the fuel tank.

Clutch



DISASSEMBLY

1. Drain the oil from the primary chaincase.

2. Take out the four screws and remove the clutch inspection cover. Unscrew the large locknut and the adjuster nut from the end of the clutch release rod.

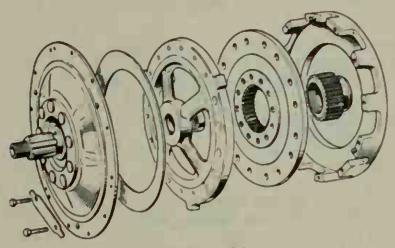
3. Back off the primary chain adjuster, remove the fourteen screws, and pull off the primary cover. Note that the screws are of different lengths; they must be replaced in their original positions.

4. Bend back the locktab, install oil seal protector 61-6051, and unscrew the engine sprocket retaining nut. Remove the transmission sprocket (clutch hub), retaining nut and pull both sprockets off together using Triumph tools D1860 and 61-6046—or suitable gear pullers.

Removing the clutch hub

5. To remove the inner crankcase (clutch) cover, first take out the screws and bolts that secure the cover, noting their positions to facilitate reassembly. Pull off the inner cover, taking care not to damage or lose the oil pump O-rings.

6. Take off the spacer and pull the



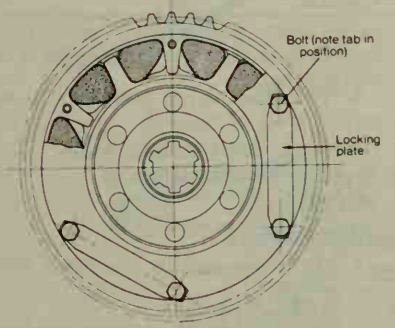
clutch unit off the shaft.

7. Mark the relative positions of the clutch cover, drive plate, and pressure plate. Bend back the locktabs on the twelve cover bolts and loosen the bolts gradually, a turn at a time, to prevent distortion of the cover.

8. Separate the clutch components, taking care not to lose the three dowel pins in the cover.

INSPECTION

Examine the drive plate and pressure plate for cracks, scoring, and overheating (extreme blue discoloration). Check to see that the drive plate slots and pressure plate tabs are not broken or excessively worn. The diaphram spring may be reused unless it shows signs of being overheated, in which case it may have been weakened. If the bearing is worn and/or the oil seal damaged, replace both components.



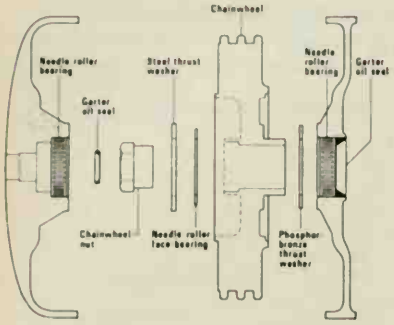
Clutch assembly

ASSEMBLY

1. Apply a small amount of high temperature grease to the sides of the three pressure plate tabs and assemble the pressure plate, disc, and drive plate (aligning the positioning marks).

2. Apply a small amount of grease to the machined ridge on the pressure plate and install the diaphram on the ridge with the outer edge of the spring upward.

3. Lightly grease the ridge inside the cover and install the cover (in alignment with the drive plate and pressure plate positioning marks) and install the twelve bolts using new locktabs. Tighten finger-tight only.



Late type shock absorber rubbers

4. Install a centering tool from the rear of the clutch and tighten the twelve bolts one-half turn at a time, working around the cover, until the cover meets the drive plate. Fully tighten the bolts and lock them with the locktabs.

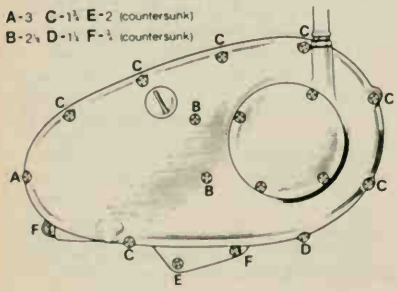
Clutch assembly order

5. Remove the centering tool, install the release rod, lightly grease the disc splines, and install the clutch on the engine.

6. Install the oil pump O-rings and check the clutch hub needle bearing for excessive play. Check the oil seal and replace if worn or deformed.

7. Apply gasket-sealing compound to the crankcase and inner cover mating surfaces. Install the cover on the crankcase using a new gasket, and tighten the screws evenly.

8. Install the twelve damper rubbers and then the outer plate. Apply thread-lock compound to the six plate-retaining screws.



NOTE: *Later models use six bolts with locktabs and a modified plate. If the screws on earlier models were found to be in need of replacement, replace the screws and plate with the later components.*

9. Install the thrust washer on the back of the damper hub, fit the primary chain over the sprockets, and install the sprockets, on the shafts. Tighten the crankshaft sprocket nut to 60 ft lbs and lock in position with the locktab. Install the spacer and tighten the mainshaft sprocket nut to 60 ft lbs.

10. Install the thrust bearing and replace the primary cover using gasket cement and a new gasket.

11. Adjust primary chain tension.

12. Install the large clutch adjusting nut, taking care not to damage the oil seal on the release rod threads. Insert an 0.005 in. feeler gauge between the bearing and large nut, and tighten the small locknut while holding the release rod from turning. Refill the primary chaincase with oil and check the clutch for correct operation.

Primary Drive Service

Follow steps 1-4, above, for clutch disassembly. Inspect the sprockets for worn and broken teeth. If the sprockets are to be replaced, the chain should be replaced also or else the new sprockets will be ruined in a short time.

Transmission Countershaft Sprocket

1. Remove the small clutch hub and clutch housing.

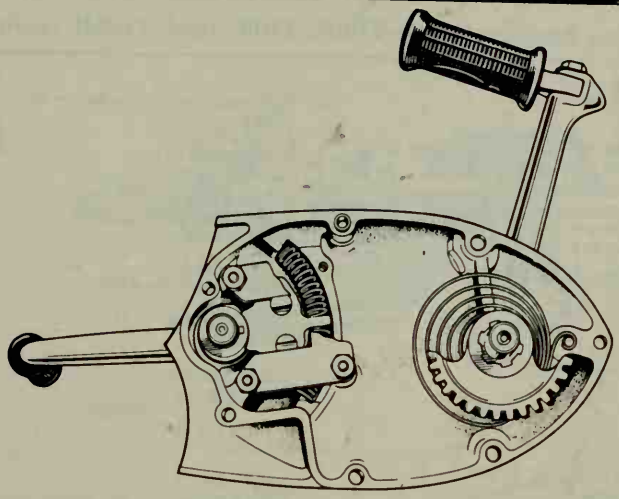
2. Remove the clutch hub retaining nut and pull the hub using a suitable gear puller.

3. Remove the clutch housing from the crankcase. Check the oil seal for wear and distortion, and replace if necessary. Unscrew the sprocket nut and then remove the final, drive-chain master link. Pull the sprocket off the shaft.

4. To replace the sprocket, install it on the shaft using hardening gasket cement on the sleeve gear splines to prevent oil from leaking between the sprocket and sleeve gear.

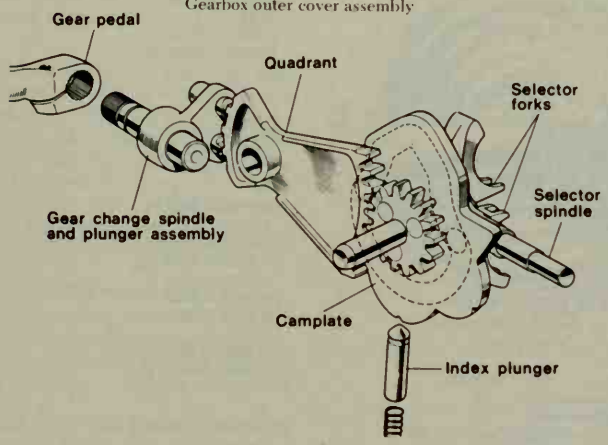
5. The remainder of installation is in reverse order of removal.

Gearbox, Shifter, and Kick-Starter, Mechanisms



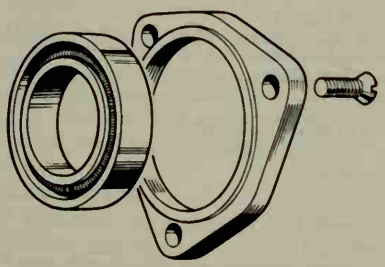
4-SPEED

Disassembly

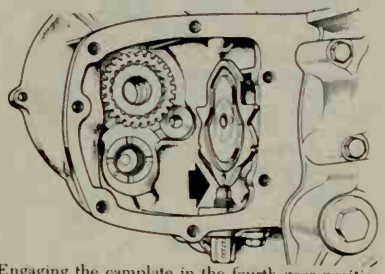


1. Drain the primary chaincase and transmission.

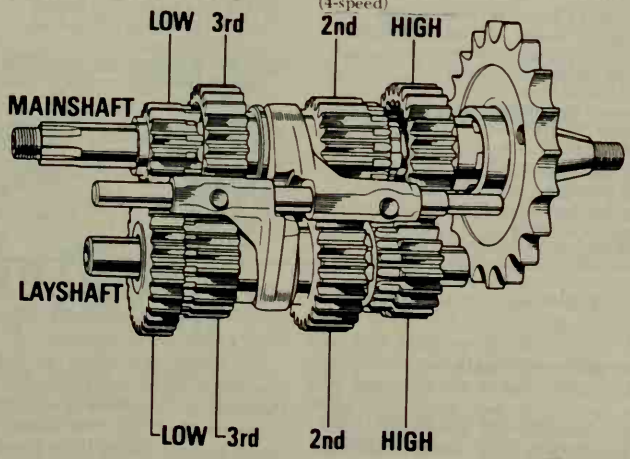
2. Remove the clutch.



3. Take out the five screws and the acorn nut, and remove the transmission outer cover complete with kick-start assembly and shifter mechanism. The kick-start half-gear is a press fit onto the shaft. If the return spring is to be replaced, load it 1¼ turns before slipping the hook over the dowel pin. The kick-start seal is accessible after the kick-start lever is removed.



Gearbox outer cover assembly



Shifter mechanism

High gear bearing oil seal and housing

Engaging the camplate in the fourth gear position (4-speed)

Gearbox components

4. To remove the kick-start ratchet and gear, bend back the locktab and unscrew the transmission mainshaft nut. If a new gear is to be installed, use a new spring also. The ratchet need not be removed for removal of the transmission gears.

5. Take out the two screws and bolts and remove the transmission inner cover, complete with selector quadrant and mainshaft assembly. Note the countershaft thrust washer located on the inner face of the cover by a small peg.

6. Unscrew the plug from the base of the transmission case that retains camplate plunger and spring.

7. Pull out the shift fork shaft and remove the countershaft first gear. Remove the sliding gears and selector forks from the case.

8. Pull the countershaft assembly out of the case and then remove the shift camplate. The countershaft top gear or sleeve pinion is attached to the final drive sprocket by a large nut.

Assembly

1. Install the high gear into the bearing and then the final drive sprocket into the case.

2. Lubricate and install the camplate shaft into the case.

3. Install the camplate plunger and spring, with retaining plug, under the transmission case, and the fiber washer.

4. Set the camplate with the plunger located in the high gear notch. Install the the thrust washer over the inner needle bearing. The grooved surface of the washer should face the countershaft. The washer can be held in place with grease.

5. Lubricate the components and assemble the countershaft and mainshaft gear clusters.

6. Place the camplate rollers on the shift forks, holding them in position with grease. Install the shift forks in their respective gears. The fork with the smaller radius is for the mainshaft cluster.

7. Install the mainshaft and countershaft gears, align the gears so that the shift fork rollers are located in the camplate tracks, and align the shift fork bores as closely as possible.

8. Lubricate the fork shaft and install it through the forks, shouldered end first, until it is fully engaged in the case. (The mainshaft shift fork should be at the innermost position).

9. Make sure the camplate quadrant is able to move freely in the inner cover. Position the countershaft thrust washer over the needle bearing in the inner cover, holding it with grease.

10. Lubricate all the transmission components. Apply gasket cement to the inner cover and transmission mating surfaces, make sure that the two dowel pins are in position, and install the inner cover.

11. Temporarily install the outer cover and check to see that the shift sequence is correct by operating the shift lever while turning the final drive sprocket. If the shift sequence is not correct, remove the inner cover and make sure the quadrant teeth are accurately engaged with the camplate gear. When reinstalling the inner cover, sure the top of the first tooth

is on the centerline of the mainshaft.

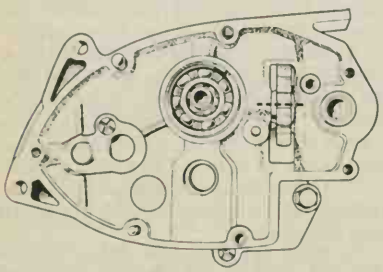
12. Reassemble the kick-shaft ratchet and gear, tightening the nut 40–45 ft lbs. To facilitate this, install the final drive chain, put the transmission in gear, and apply the rear brake.

13. Install the outer cover using gasket cement on both mating surfaces.

14. Install the clutch.

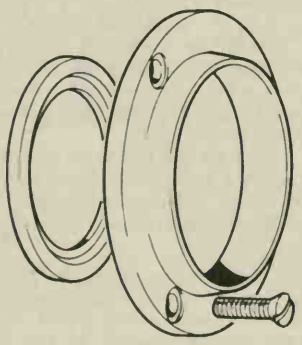
5-SPEED

The Trident T150V (5-speed) utilizes a transmission which is quite similar to the 5-speed found in the TR7V and T140V. For service procedures, refer to the earlier section dealing with the transmission for the 750 Twins.



One difference between the 750 Twin transmission and that for the T150V is that the latter has a high gear bearing oil seal which is found in a housing secured by three screws.

Bottom End



DISASSEMBLY

1. Drain the oil from the crankcase, transmission, and primary drive. Remove the engine.

2. Remove the cylinder head, barrel, and pistons.

Inner cover installed with quadrant aligned

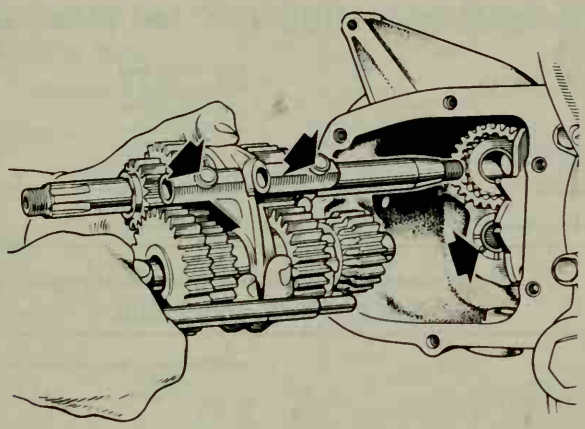
Mainshaft high gear oil seal and housing (5-speed)

3. Remove the primary drive and clutch assembly.

4. Remove the transmission gear cluster.

5. Remove the ignition points cover. Scribe a line on the breaker plate housing to facilitate reassembly, take out the three bolts, and remove the breaker plate assembly. Unscrew the bolt in the center of the breaker cam and remove the ignition advance unit with tool no. D782, or by screwing in a bolt that fits the threads in the cam until the advance unit is broken loose.

6. Take out the screws and remove the timing gear cover (right crankcase cover).



7. Unscrew the three nuts and pull the alternator stator off the studs. Unscrew the cable sleeve nut (covered by a rubber grommet) and pull the cable through.

8. Bend back the locktab and unscrew the alternator rotor retaining nut. Pull the rotor off the shaft, leaving the key in place to prevent the crankshaft timing gear from turning.

9. Before removing the timing gears, take note of the marks on the gear teeth that will line up if the gears are installed correctly. Pull the crankshaft pinion off using tool no. 61-6019 or a suitable gear puller.

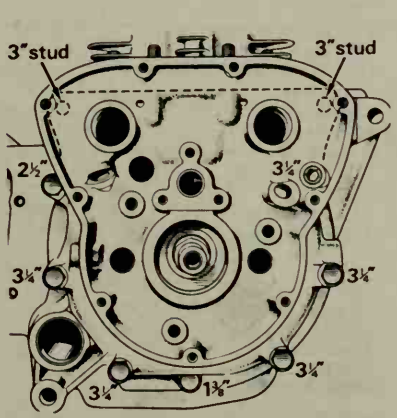
Installing the gearbox components

10. Remove the circlip and pull off the idler (center) timing gear and its thrust washer.

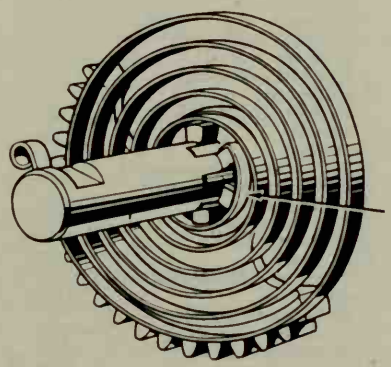
11. To unscrew the two camshaft, timing-gear retaining nuts, it will be necessary to lock the crankshaft in position by inserting a bar through two of the connecting rods. Take care not to damage the crankcase. Unscrew the nuts, *which have left-hand threads*, and pull off the camshaft timing gears using tool no. D2213 or a suitable gear puller. Remove the woodruff keys.

12. Take out the three bolts and remove the tachometer drive which is located just above the front engine mount.



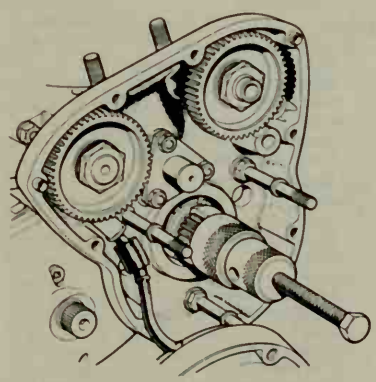
13. Remove the oil filter from the bottom of the crankcase, held in place by a large brass plug.

14. To separate the crankcases, first take out the hex bolts, allen bolt, and the six nuts from the timing side crankcase as shown in the illustration.



15. Next, remove the hex-head bolts from the drive-side crankcase. Tap off the drive-side crankcase using a soft metal drift. Place the drift against the lug at the rear of the case.

CAM SHAFTS



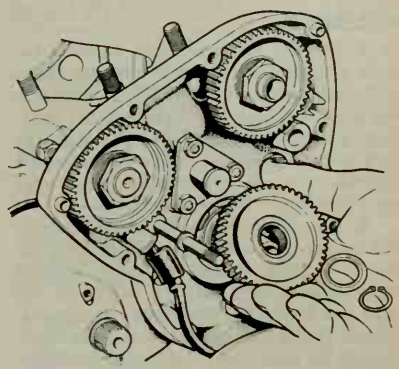
Withdraw the camshafts from the timing side crankcase and examine the lobes for wear and damage. Examine the tachometer drive gear on the exhaust camshaft for broken or worn teeth. Replace the camshafts if they do not appear to be in perfect condition.

Right case securing bolts

Kickstarter return spring installation

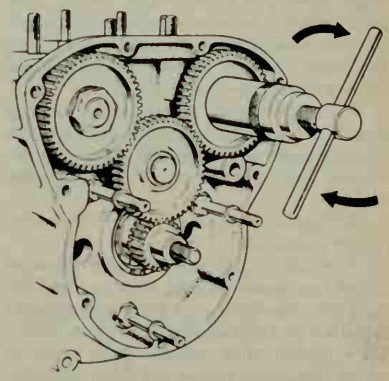
Removing the crankshaft pinion

CRANKSHAFT REMOVAL



1. Remove the retaining screws from the two small oil lines on top of the main bearing journal caps, pull the lines up, turn them away from the caps, and push them down and out of the crankcase.

2. Remove the locknuts from the main bearing caps. To remove the caps, screw the oil line screws, with washers, back into them and pry the caps off the studs with levers.

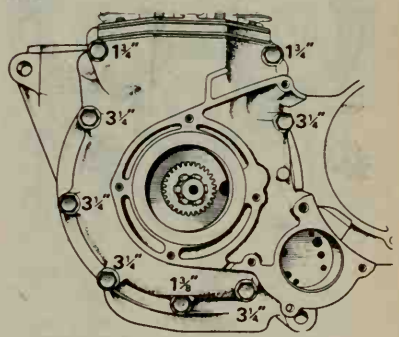


3. The crankshaft assembly can now be removed.

CENTER MAIN BEARINGS AND CONNECTING ROD BEARINGS

The crankpins and the two center crankshaft journals run on replaceable, plain bearing inserts. Be sure to mark the rods and caps before removal so that they may be replaced in their original positions. It will be necessary to regrind the crankshaft if journal or crankpin wear exceeds 0.002 in. or if their surfaces are damaged. Bearings are available in 0.010, 0.020, 0.030, and 0.040 in. undersizes. The crankshaft assembly will *not* require rebalancing if components are replaced or if the crankshaft is reground.

Removing the idler timing gear



Removing the camshaft pinions

OUTER MAIN BEARINGS

If they are to be removed, it will be necessary to remove the circlips on either side of the bearing.

NOTE: *The center of the timing side roller bearing will remain with the crankshaft as the crankshaft is removed.*

Oil seals should be replaced at this time to avoid future trouble. Take care not to damage seals during installation. The flat side of the seal always faces outside.

Left case securing bolts

ASSEMBLY

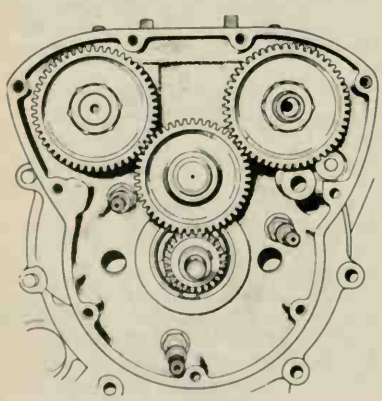
1. Fit the rod and main bearing inserts into their seats and lubricate them with fresh engine oil. Install the connecting rods and caps in their original positions and tighten the nuts to 18 ft lbs. Use new nuts if possible. Make sure that all components are completely clean and well lubricated during assembly.

2. Place the crankshaft in position in the crankcase, with the splined end on the drive side. Install the main bearing caps, making sure that the marks on the caps and lower bearing seats correspond. Install the washers and nuts (new nuts should be used) and tighten to 18 ft lbs. Check to see that the crankshaft is free to rotate easily. If it will not, switch the main bearing inserts around, make sure they are seated properly and re-oil them. Too tight a fit will require turning down the crankshaft journals slightly.

3. Install new rubber seals for the tappet oil lines (connecting at the main bearing caps) and install the lines as removed, taking care not to damage the seals.

4. Replace the oil filter O-rings in the center crankcase.

5. Apply a thin coat of gasket cement to the crankcase mating surfaces and install the crankcases (with the camshafts installed in the turning side case) in reverse order of removal. Take care to avoid damaging tappet oil lines with the exhaust camshaft as the turning side case is installed. Tighten the nuts and bolts evenly to 15 ft lbs.



6. Check that the crankshaft and camshafts are free to rotate freely. If not, alignment is incorrect somewhere and must be corrected.

7. Install the crankshaft spacer on the timing side and then install the special key and crankshaft timing gear (with the mark facing out).

8. Install the camshaft timing gears with the no. 1 keyway (in line with the timing mark) located on the key in the shaft, and with the timing marks facing out. Install and tighten the left-handed-threaded retaining nuts.

9. Install the idler timing gear, aligning the timing marks as shown.

10. Install the alternator rotor, tightening the nut to 50 ft lbs. Install the stator and tighten the nuts to 8 ft lbs.

11. Loosely install the ignition advance unit and then install the breaker plate assembly, aligning the marks. Coat the crankcase and cover mating surfaces with gasket cement and install the timing side crankcase cover, using a new gasket.

12. Install the oil filter in the bottom of the engine.

13. Install the tachometer drive unit, coating the gasket with gasket cement on both sides. Tachometer drive components generally do not require replacement unless an obvious fault is visible.

14. Install the transmission gear cluster as detailed earlier.

15. Install the primary drive and clutch.

LUBRICATION SYSTEMS

TR25W

Scavenge Non-return Valve

The scavenge non-return valve is located within the oil return pipe in the engine sump. It's a good idea to check its operation whenever the sump strainer screen is removed.

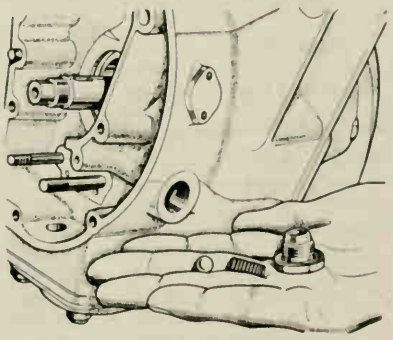
Scavenge non-return valve (250)

Poke a piece of wire into the pipe and force the check ball out of its seat. Allow it to drop back down of its own weight. If the ball does not seat itself properly, this indicates a sludge buildup in and around the valve. If necessary, immerse the return pipe in gasoline and let it sit until the check ball operates freely.

Feed Non-return Valve

The oil feed non-return valve is located in the inner timing cover of the engine. Check its operation as described above and, if necessary, clean it with gasoline.

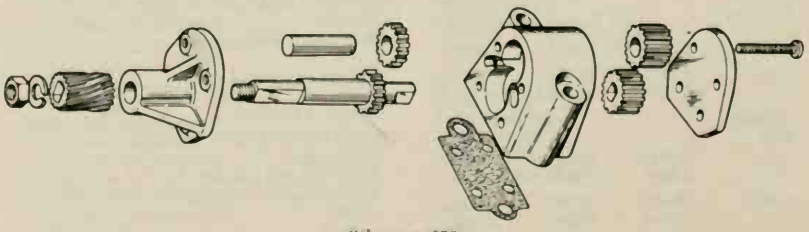
If you have a problem with the engine sump filling with oil whenever the bike is left to sit, chances are that a malfunction of this valve is the cause.



Crankcase Oil Line Union

The oil line union is secured to the crankcase with one nut. If a leak has developed at this junction, disconnect the oil lines and inspect the union sealing O-rings. Replace if necessary.

When reinstalling the union, note that the oil lines are correctly connected when they are crossed (i.e., outer line from the oil tank to the inner connection of the union).



Oil Pressure Relief Valve

The oil pressure relief valve is located at the front right side of the crankcase. Should oil pressure exceed a pre-set limit, the valve routes the excess oil directly back into the sump.

Oil pressure relief valve (250)

To remove the valve, unscrew the hexagonal plug and withdraw the ball and spring. Inspect them for corrosion etc., and replace them if necessary. The spring will, in time, lose its strength, so it is advisable to replace it if the machine has accumulated high mileage. Also replace the fiber washer if it is in less than perfect condition.

Oil pump (250)

Oil Pump

The oil pump is located at the front right side of the engine inside the case cover.

DISASSEMBLY

1. Remove the four screws at the base of the pump and remove the baseplate and top cover.
2. Mark the worm gear for reassembly, then remove the nut and washer that secure the gear and driving spindle to the top cover.
3. Clean all parts thoroughly in kerosine or a cleaning solvent and blow them dry with compressed air.

INSPECTION

Examine the oil pump parts for excessive scoring and foreign object damage. If oil changes have been neglected, it will be evident by the damage done to the pump gear teeth and pump body. Small scratches can be ignored, but any more substantial wear calls for parts replacement.

Inspect the pump gears for worn or broken teeth. If formerly sharp edges have become rounded off, the gear should be replaced.

ASSEMBLY

1. Make sure all parts are absolutely clean and bathed in engine oil or assembly lube.
2. Insert the driving spindle into the pump top cover.
3. Install the worm drive gear and secure it with the nut and spring washer.
4. Install the driven spindle and gear in the top cover.
5. Install the lower pump gears and baseplate.
6. Rotate the spindle and gears to make certain there is no binding, then tighten the four securing screws.
7. Check the joining surfaces of the oil pump to make sure they are all parallel. If not, the pump may not be free to operate when installed in the engine.
8. Also check the crankcase breather located near the clutch cable abutment in the timing case. This breather *must* be free from obstruction.

500, 650, 750 TWINS

Checking Oil Pressure

Normal oil pressure at idle is about 20 to 25 psi, but may rise as high as 80 psi when the engine is cold. Normal running pressure is 65 to 80 psi.

Oil pressure can be checked by connecting a gauge and adaptor in place of the relief valve.

Oil Line Junction Block

REMOVAL AND INSTALLATION

1. Drain the transmission oil.
2. Remove the gearbox outer cover as described in "Engine and Transmission."
3. Drain the oil tank.
4. Disconnect the rubber lines from

the oil tank.

5. Remove the junction block and clean it thoroughly in kerosine.

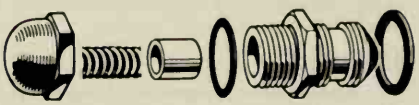
6. Check all lines for chafing and signs of decomposition. Replace as necessary.

7. Installation is basically a reversal of the removal procedure. Use a new gasket between the junction block and crankcase, and reconnect the oil lines carefully.

Rocker Oil Feed Line

REMOVAL AND INSTALLATION

1. Remove the two domed nuts securing the feed line to the rocker spindle.



2. Disconnect the feed line at the oil tank.

3. Remove the clips securing the feed line to the frame.

NOTE: *Take care not to bend the feed line when removing it from the frame beecause it may cause a future rupture.*

4. Thoroughly clean the oil feed line with kerosine, then blow it out with compressed air.

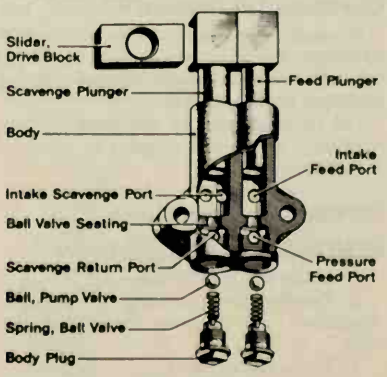
5. Check the line for proper sealing by holding your thumb over the banjo fitting at one end of the line and blowing through the other.

Pressure relief valve (Twins)

6. To install the rocker oil feed-line, reverse the removal procedure and replace the banjo fitting washers.

Oil Pressure Relief Valve

The valve is located at the front of the engine on the right side, adjacent to the timing cover.



REMOVAL AND DISASSEMBLY

1. Remove the valve body by unscrewing the hexagonal cap.

2. Separate the cap from the valve body and withdraw the piston and spring.

3. Thoroughly clean all parts in kerosine, then inspect the piston and spring for signs of wear. Also check to make sure the valve filter is free from obstruction.

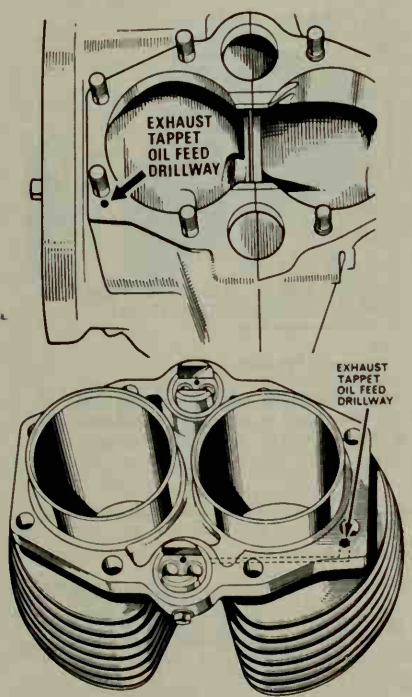
4. If the bike has accumulated high mileage it is advisable to check spring pressure with the standard figure given in specifications.

Oil pump (Twins)

ASSEMBLY AND INSTALLATION

1. Replace both fiber washers with new ones.
2. Assemble the valve body, piston, and spring.

NOTE: *The open end of the piston should face toward the spring and cap.*



3. Install the valve body and screw on the hexagonal cap.

Oil Pump

The oil pump is located inside the timing cover and is driven off the end of the intake camshaft. Since the pump itself is totally immersed in oil, wear on internal parts should be negligible. The oil pump drive block slider is not as well lubricated, however, and therefore should be replaced when the machine has accumulated high mileage.

REMOVAL AND DISASSEMBLY

1. Remove the timing cover.
2. Remove the two oil pump securing nuts.
3. Lift the oil pump off the mounting studs.

Tappet oil feed drillways

4. Remove the scavenge and feed plungers.
5. Unscrew the two square end caps and remove the two springs and balls.
6. Clean all parts in kerosine, then inspect them for scoring, pitting, and excessive wear. Measure plunger diameters and spring compressed strength. Standard values are given in the specifications.

ASSEMBLY AND INSTALLATION

1. Lubricate all parts generously with engine oil.
2. Assemble the plungers, balls, springs, and end caps.

3. Add approximately 1 cc of oil in each plunger bore, then press the plungers until the oil is forced through both outlet ports.

NOTE: *The outlet ports are the two holes nearest the square end caps.*

4. Hold your thumb over the intake ports (nearest the plunger tops) and pull the plungers out slightly. If the oil level drops in either outlet port, the ball and spring in that port are not seated properly, and the end cap should be removed and the cleaning process repeated.

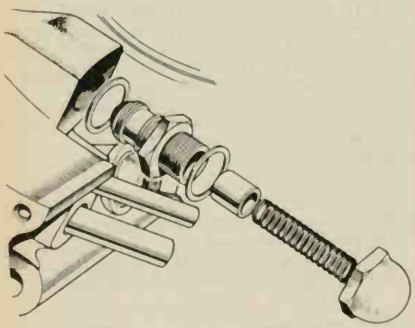
NOTE: *On machines equipped with a brass body oil pump, the balls can be lightly, but sharply, tapped to ensure a good seal. On machines equipped with the cast iron pump body, however, this should not be attempted since a bad seal indicates a warped body that should be replaced.*

5. Check the oil pump drive block slider for excessive wear, then install the pump with a new gasket. Make sure that the conical securing nuts are positioned so that they fit into the countersunk holes in the pump body.

6. Clean the timing cover and crankcase mating surfaces, then apply fresh sealing compound and install the cover.

T150, T150V

Checking Oil Pressure

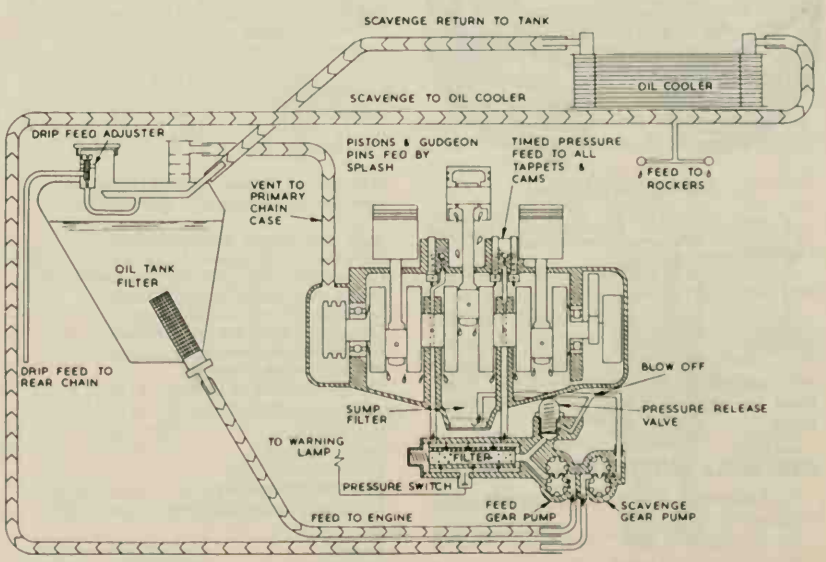


Normal running oil pressure at 3,000 rpm is 75–90 psi, but may rise above that when the engine is cold. Pressure can be checked by installing an oil pressure gauge in one of the blanking plugs at the front of the center crankcase.

If the oil pressure is unsatisfactory, check the following:

1. Faulty or dirty oil pressure relief valve.
2. Insufficient amount of lubricant in the oil tank.
3. Dirty or incorrectly installed oil filters.
4. Faulty oil pump.
5. Obstructed crankcase drillings.
6. Excessively worn main or connecting rod bearings.
7. Leaking crankcase union O-rings.

Oil Pressure Relief Valve



The oil pressure relief valve is located in the primary chaincase. Triumph special tool no. D2135 can be used to remove the valve with only the primary cover removed, but if this tool is not available,

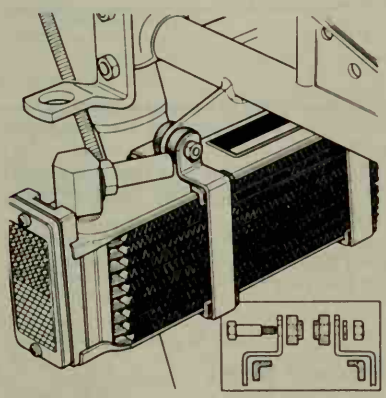
Trident lubrication system

the chaincase must be disassembled to gain access.

Disassemble and inspect the valve as described for the 500, 650 and 750 cc Twins.

Rocker Oil Feed Line



Service the rocker oil feed line as described for the twins.

Oil Cooler

The Trident is equipped with an oil cooler mounted below the gas tank on two support brackets. Great care should be taken when handling this component.

REMOVAL

1. Remove the gas tank.
2. Mark both oil lines for reassembly, then disconnect the clips. Take care not to tilt the cooler as it still contains approximately one-half pint of oil.
3. Loosen the top support bracket bolts and remove the bracket corner packings.

Oil cooler installation

4. Hold the cooler upright and remove the bracket bolts, nuts, and washers.
5. Lift out the cooler, then drain the remaining oil by inverting the cooler over a suitable container.
6. Clean the outside of the cooler with kerosine and a soft-bristled brush. It is not necessary to flush the cooler.

INSTALLATION

Installation is a reversal of the removal procedure. Note the following:

1. The large oil line fittings at the top of the cooler should face rearward when the cooler is installed.
2. When the cooler is properly installed, the left oil line fitting should be connected to the scavenge line and the right fitting to the oil tank return line.

Oil Pump

The oil pump is the double-gear type and is mounted in the primary side crankcase. Drive is provided by the crankshaft via reduction gears. Since the pump is immersed in oil, wear should be negligible on all but the feed and scavenge drive gears.

REMOVAL

1. Remove the outer and inner primary chaincases (See "Engine and Transmission").

2. Remove the four attaching screws and lift out the oil pump assembly.
3. Remove the two remaining screws and separate the pump parts.
4. Drive out the gear spindles with a thin, soft alloy drift.
5. Wash all parts thoroughly in cleaning solvent or kerosine, then blow them dry with compressed air.

INSPECTION

Examine the gear teeth for scoring or rounded out edges. Check the spindles and spindle bores in the gears and pump body. Replace any parts that are excessively worn.

INSTALLATION

Installation is a reversal of the removal procedure. Note the following:

1. Replace the gasket that fits between the pump and crankcase.
2. Make certain that the two screws holding the pump body together are sufficiently tightened.
3. Make sure the pump is correctly located over the dowel in the crankcase recess.
4. Replace the O-ring that fits around the pump body in the inner primary chaincase.
5. When installing the oil pump drive gear, apply a thread-locking compound to the securing screw.

FUEL SYSTEMS

Triumph motorcycles were fitted with one or two Amal Monobloc carburetors prior to 1967, and from that date have been equipped with the Concentric version.

NOTE: *For carburetor theory, inspection, and service, refer to "Carburetors" under the "General Information" section.*

MONOBLOC

Removal and Disassembly

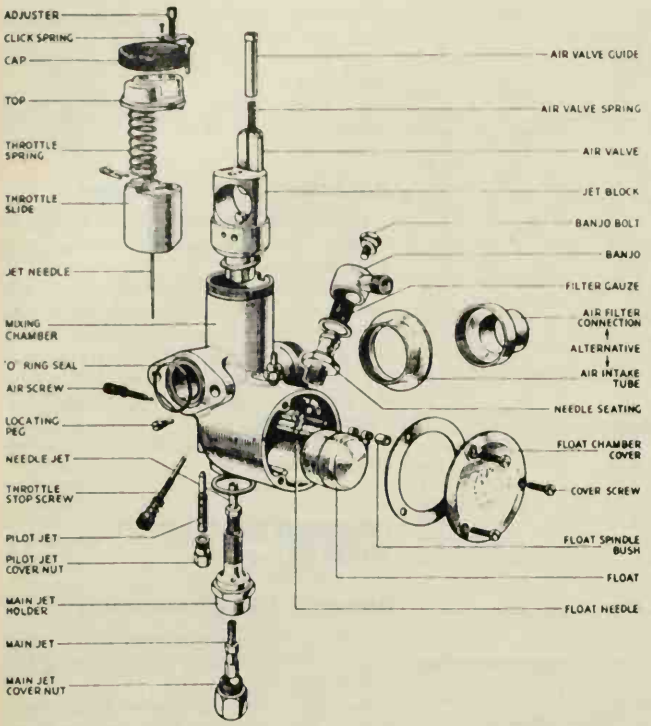
1. Remove the air cleaner(s).
2. Disconnect the fuel feed line at the carburetor banjo. Disconnect the feed line between the carburetors.
3. Gradually loosen the two carburetor flange nuts, and remove the carburetor.
4. Unscrew and remove the carburetor cap, and pull out the choke and throttle slide assembly. To disassemble, remove the needle clip, compress the spring, disengage the cable from the slide, and separate the components.
5. Remove the banjo bolt, and take off the banjo and filter screen.
6. Unscrew and remove the float needle seat. Take out the needle.
7. Remove the main jet cover nut. Unscrew and remove the main jet holder complete with main and needle jets.
8. Remove the pilot jet cover nut. Unscrew and remove the pilot jet.
9. Remove the float bowl cover (3 screws). Remove the float spindle, float, and spindle bush.
10. Remove the pilot air and throttle stop screws.
11. Remove the locating peg, and shake out the jet block.

Assembly and Installation

1. Assembly is the reverse of disassembly. Use new gaskets, O-rings, and fiber washers.
2. Install the throttle slide(s) in the carburetor(s) before tightening the flange nuts. Tighten these nuts slowly and evenly. Check for free slide movement as the nuts are tightened. If the slide sticks, the nuts are overtightened, warping the carburetor body.
3. After connecting the fuel line(s), check for leaks.

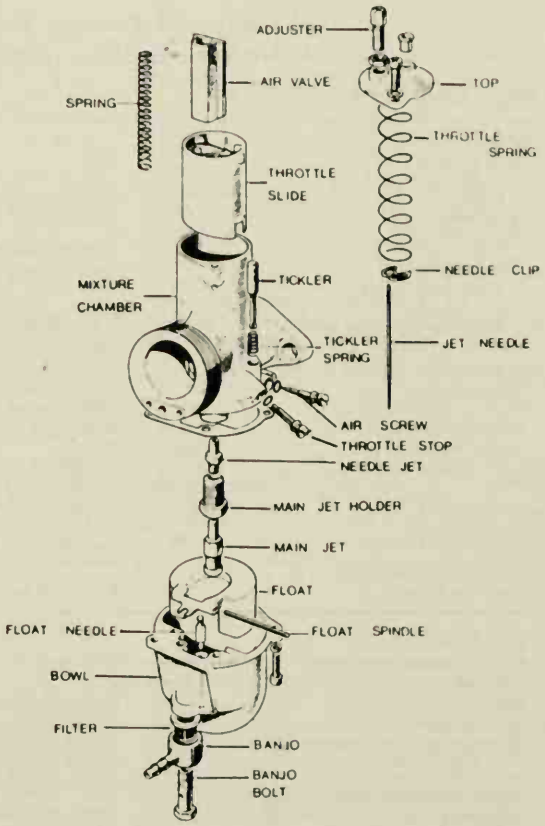
CONCENTRIC (EXCEPT TRIDENT)

Removal and Disassembly



1. Remove the air cleaner(s).
2. Disconnect the fuel feed lines at the carburetor(s).
3. Loosen the carburetor flange nuts evenly, then remove them and pull off the carburetor.
4. Remove the carburetor top and pull out the slide assembly. To disassemble, remove the needle and clip by compressing the return spring against the cap, compress the return spring and disengage the cable from the slide.
5. Remove the float bowl banjo bolt, with banjo and filter.
6. Remove the float bowl screws, tapping the bowl lightly to free it if stuck.

NOTE: *Hold the carburetor in the upright position when removing the float bowl.*



7. Remove the float assembly from the float bowl. The float spindle is pressed lightly into the bowl.
8. Unscrew and remove the main jet holder complete with main and needle jets.
9. Unscrew and remove the pilot jet (if fitted), pilot air screw, and throttle stop screw.

Assembly and Installation

1. Assembly is the reverse of disassembly. Use new O-rings (the condition of the flange O-ring is critical), float bowl gasket, and washers.
2. If plastic banjos are fitted, do not overtighten them, or they may leak.
3. Put the throttle slide assemly in the carburetor body before bolting it down. Be sure the flange O-ring is seated in its groove and hold the carburetor against its manifold while screwing on the nuts.
4. Tighten the flange nuts gradually and evenly, checking for free slide movement as this is done. Overtightening or uneven tightening of the nuts may cause the slide to stick because it may warp the body.
5. After connecting the fuel line(s), check for leaks.

TRIDENT

The Trident is equipped with three, Model 600 Concentric carburetors. These units differ from the other Concentric carburetors in that the throttle slide has no conventional throttle spring, but is returned by a scissor spring located on the external throttle linkage.

Removal and Disassembly

1. Remove the side panels and the fuel

2. Disconnect the throttle cable from the throttle linkage and disconnect the choke cable from the handlebar lever.

3. Remove the air cleaner assembly out the left side of the machines.

4. Remove the two screws securing each carburetor top, then remove the manifold nuts and pull each carburetor back and down, leaving the slide assemblies fastened to the throttle linkage.

5. To remove the carburetor top and slide assemblies, disconnect the slide from the throttle rod and the air valve from its cable. Remove the jet needle retaining clip and compress the throttle rod return spring to free the top retaining plate. Push the bottom nipple of the throttle rod down to clear the throttle slide and compress the air valve spring to free it from the cable end nipple.

6. Unscrew the air valve cable abutment to completely remove the carburetor top.

7. The remainder of the disassembly procedure is the same as for the standard Concentric. Refer to the "Concentric: Removal and Disassembly" section preceding, Steps 5–9.

Assembly and Installation

Refer to "Concentric: Assembly and Installation" section preceding.

ELECTRICAL SYSTEMS

IGNITION SYSTEM

Troubleshooting

TR25W

1. Make sure the contact breaker is clean and correctly gapped. Also make certain the battery terminals are tight and in good condition.

2. Check the main wiring harness fuse.

3. Turn the ignition switch on and slowly turn the engine over while watching the ammeter needle. As the contact breaker opens and closes, the needle should flick between zero and a slight discharge. If it does not, there is a fault somewhere in the low tension circuit.

4. Recheck the condition of the points to make sure you aren't getting a false indication due to dirt, oil, or an incorrect adjustment.

500 AND 650 TWINS

1. Check the condition and gap of the contact breaker points and the tightness of the battery terminals.

2. Remove the gas tank.

3. Disconnect the white lead that connects the "SW" terminals of both ignition coils.

4. Connect the white lead to the left coil "SW" terminal, then turn on the ignition switch and slowly turn over the engine while observing the ammeter needle. As the contact breaker opens and closes, the needle should flick between zero and a slight discharge.

5. Disconnect the white lead from the left coil and connect the "SW" terminal of the right coil. Turn the ignition switch on and observe the ammeter needle as described above.

6. If the ammeter needle does not flick in the described manner for both the right and left ignition coils, a fault exists in the low tension circuit.

T150

1. Lift up the seat and disconnect the white lead that connects the "SW" terminal of all three ignition coils.

NOTE: *Lucas coils are marked "SW" and "CB." SIBA coils are marked "1" instead of "SW" and "15" instead of "CB."*

2. Connect the white lead to one coil at a time and check ammeter needle deflection as previously described for the other models.

750 TWINS, T150V

Procedures are essentially as described above, except that the coil wires are white/yellow.

Low Tension Circuit Tests

If the above tests showed that the fault exists somewhere in the low tension circuit, isolate the problem source in the following manner:

NOTE: *On 12 volt machines, disconnect the zener diode center terminal.*

1. Place a piece of non-conducting material between the contact breaker points. Turn the ignition switch on.

2. Using a 0–15 volt DC voltmeter (0–10 volts for 6 volt machines) and the appropriate wiring diagram for reference, make point-to-point checks as described below.

3. Check the battery by connecting the voltmeter between the negative terminal of the battery and ground (frame). No reading indicates a blown main, or a faulty red, battery lead; a low reading indicates a poor ground.

4. Connect the voltmeter between the ignition coil negative terminal (SW or 1) and ground (one at a time on twins and triples). No reading indicates a faulty lead between the battery and coil terminal, or a faulty switch or ammeter connection.

5. Connect the voltmeter between ground and one ammeter terminal at a time. No reading at the "load" terminal indicates either a faulty ammeter or a break in the blue/brown lead from the battery; no reading on the battery side in-

dicates a faulty ammeter.

6. Connect the voltmeter between the ignition switch "feed" terminal and ground. No reading indicates a break or faulty terminal along the brown/white lead. Check for voltage readings between ground and the brown/white lead terminals at the rectifier, ammeter and lighting switch (on singles and twins.)

7. Connect the voltmeter between the ignition switch "load" terminal and ground. No reading indicates a faulty switch. A positive reading at this point, but not in step 4, indicates a break or faulty connection along the white lead.

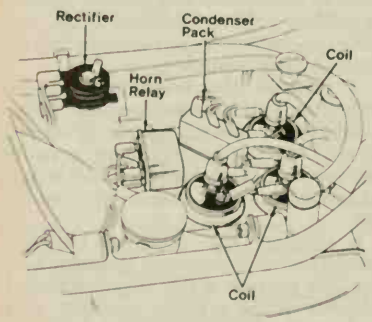
8. Disconnect the ignition coil lead from the positive (CB or 15) terminal and connect one voltmeter lead in its place (one coil at a time on twins and triples). Connect the other voltmeter lead to ground. No reading indicates a faulty primary coil winding.

9. Reconnect the ignition coil lead(s) and connect the voltmeter across the contact breaker points one set at a time. Leave the rubber insulator in place. No reading indicates a faulty connection, faulty insulation, or a faulty condenser.

10. On 12 volt machines, reconnect the zener diode center terminal and connect the voltmeter to this terminal and ground. The meter should read battery output voltage.

High Tension Circuit Tests

If the preliminary ignition system checks showed that the problem lay in the high tension circuit, check the following:



1. Test the ignition coil(s) as described in component tests. If the coils are in satisfactory condition, either the high tension cables or spark plug cap(s) are at fault.

2. Remove the spark plug cap(s) from the cable(s) and turn the ignition switch on. Hold the cable about ⅛ in. away from the cylinder cooling fins and kick the engine over. A bright blue spark should jump across the gap; if not, the cable is defective. If the spark does appear, the spark plug cap is faulty.

Component Tests

IGNITION Coil

1. Check the coil in the machine by removing the spark plug cap and holding the high tension cable end about ⅛ in. away from the cylinder cooling fins. Turn the ignition on and kick the engine over.

Component location (Trident)

2. Check primary winding resistance by removing the coil and connecting an ohmmeter to the low tension terminals. The readings obtained should be:

TR25W

3.0 ohms minimum
3.4 ohms maximum

T100C, T100R, TR6C, TRGR, and T120R
MA6 type

1.8 ohms minimum
2.4 ohms maximum

MA12 type

3.0 ohms minimum
3.4 ohms maximum

T150, T150V

3.3 ohms minimum
3.8 ohms maximum

TR7V, T140V

3.0 ohms minimum
3.4 ohms maximum

3. Inspect the high tension cables for any signs of insulator deterioration.

CONDENSERS

A faulty condenser is usually indiated by burning or arcing of the points. On the TR25W, the consenser is located under the ignition plate in the primary chaincase; on twins and triples, they are located under the gas tank.

To check the condenser(s), first turn the ignition switch on, then take readings across the contact breaker(s) (open position) with a voltmeter. No reading indicates that the condenser insulation has broken down, and the unit should be replaced.

CHARGING SYSTEM

The charging system consists of an alternator and a full-wave bridge rectifier that converts the AC pulses in DC for recharging the battery and powering the lights. 12 volt machines are also equipped with a zener diode to absorb any excess charge.

Alternator Output Test

TR525W

1. Disconnect the two or three alternator output leads.

NOTE: *Earlier machines have three leads; later machines have two.*

2. Start and run the engine at 3,000 rpm.

3. Connect a 0–15 volt AC voltmeter with a 1 ohm load resitor in parallel with each of the alternator leads as described below.

4. Three-lead-type stator:

a. White/green and green/black leads—minimum voltmeter reading 4.0 volts.

b. White/green and green/yellow leads—minimum voltmeter reading 6.5 volts.

c. White/green and green/black with green/yellow leads—minimum voltmeter reading 8.5 volts.

5. Two-lead-type stator:

a. White/green and green/yellow leads—minimum voltmeter reading 8.5 volts, for all except 47205 stator (9.0V).

6. If low or no readings are obtained, inspect the leads for damage and make sure they have tight connections. Check the alternator output again, and if the same results are obtained the difficulty lies in the alternator itself and it must be replaced.

7. To check for grounded coils within the stator, connect the voltmeter to each terminal and ground. If a reading is obtained, the coil connected to the lead being tested is grounded.

T100C, T100R, TR64, TR6C, AND T120R

Test the alternator output as described for the TR25W. Correct output readings are given in the following chart.

T150

Check alternator output for the Trident in the same manner as described for the three-lead TR25W stator. Correct output readings are given.

TR7V , T140V, T150V

These models use a 47205 stator. Procedures are same as for TR25W. Minimum voltmeter reading is 9.0 volts.

	Alternator Output Minimum AC Volts @ 3,000 rpm		
RM20 stator 47209 (12 volt)	green/white and green/black connected 5.0	green/white and green/yellow connected 8.0	green/white and green/black and green/yellow connected 10.0

Rectifier Test

Two precautions should be taken whenever handling the rectifier for testing or for any other purpose.

1. When removing or installing the rectifier, prevent any possibility of twisting the rectifier plates, which could result in broken internal wiring.

2. *Never* disturb the nuts that hold the rectifier plates together.

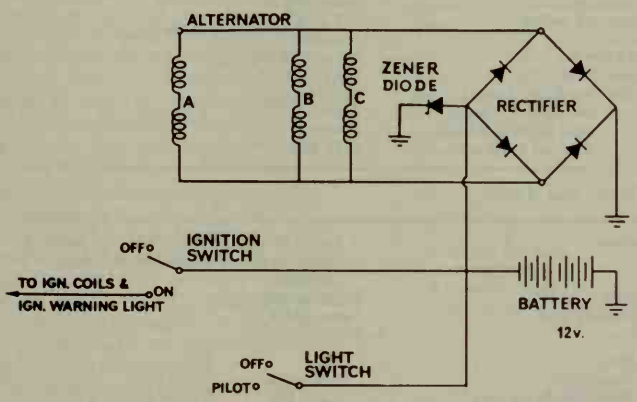
To test the rectifier in the machine:

1. Disconnect the brown/white lead from the center terminal and wrap the end in tape to prevent a short-circuit to ground.

2. Connect a DC voltmeter in parallel with a 1 ohm load resistor between the center rectifier terminal and ground.

3. On twins, disconnect the alternator green/yellow lead and connect it to the rectifier green/black lead by using the appropriate jumper cable. Make sure this connection is insulated to prevent a short-circuit.

4. Start and run the machine at 3,000 rpm and observe the voltmeter reading. It must be 7.5 volts minimum.



5. If the reading is higher than specified, check the rectifier ground. If the ground is OK, replace the rectifier. If the reading was zero or less than specified, the problem lies in the rectifier or charging system wiring. First check the rectifier on a bench.

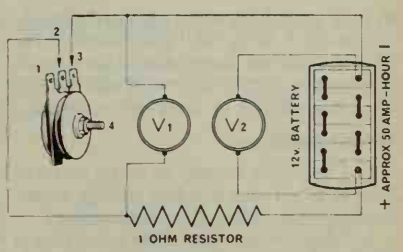
12-volt charging circuit



6-volt charging circuit

Rectifier Bench Test

1. Disconnect and remove the rectifier. Observe the note on handling the unit.

2. Connect the rectifier to a 12 volt battery and a 1 ohm load resistor.

3. Connect a DC voltmeter in the V position as shown in the accompanying illustration. The meter should read 12 volts.

Rectifier test

4. Disconnect the voltmeter and, using the accompanying illustrations for guidance, test each of the diodes with the voltmeter leads. Keep the testing time as short as possible so that the rectifier does not overheat. No reading should be greater than 2.5 volts in Test 1, and no reading should be more than 1.5 volts less than the battery voltage in Test 2 (i.e., 10.5 volts minimum).

5. If the rectifier does not meet specifications, it should be replaced.

Charging Circuit Continuity Test

If the rectifier tests did not pinpoint the problem, it must be located somehere within the charging circuit wiring. For checking continuity, the battery must be in a good state of charge and the alternator leads must be disconnected at their snap connectors.

TR25W

1. Make sure there is power at the rectifier by connecting a DC voltmeter, with a 1 ohm load resistor in parallel, between the center rectifier terminal and ground. The meter should read battery voltage.

2. If there is no voltage at the rectifier, repeat steps 3, 5, and 6 under "Low Tension Circuit Tests" to isolate the problem in the wiring.

500 AND 650 TWINS

6 Volt Machines

1. Repeat steps 1 and 2 given for the TR25W.

2. Connect the green/yellow lead from the main wiring harness (under the engine) to the rectifier center terminal with a jumper cable. Turn the ignition switch on.

3. Connect a DC voltmeter, with a 1 ohm resistor in parallel, between the green/white lead at the rectifier and ground. With the light switch in the "off" position, the meter should read battery voltage. If not, the leads to the ignition switch terminals 16 and 18, and the leads to light switch terminals 4 and 5, should be checked.

4. Connect the green/yellow lead from the main wiring harness to the rectifier center terminal with a jumper cable. Turn the ignition switch to the IGN position and the headlight switch to the HEAD position.

5. Connect a DC voltmeter, with a 1 ohm resistor in parallel, to the green/black lead at the rectifier and ground. The meter should read battery voltage. If not, the leads to ignition switch terminals 16 and 17, and the leads

to light switch terminals 5 and 7, should be checked. With the light switch in the PILOT position, there should be no voltage reading between ground and the rectifier green/black or green/white leads.

12 Volt Machines

1. Check the battery to make sure the fuse is intact and that the battery is correctly connected to ground (positive).
2. Check to see that there is voltage at the rectifier center terminal as previously described. If there is not, disconnect the alternator leads at their snap connectors under the engine.
3. Wire a jumper lead between the center and green/yellow rectifier terminals and check the voltage between the snap connector and ground. If there is no reading, the alternator harness lead is faulty.
4. Repeat the above for the rectifier green/white lead.
5. If there is voltage at the center rectifier terminal, check the ammeter terminal. If it is satisfactory here, the brown/white lead to the rectifier center connector is faulty.
6. If there is no voltage at either the rectifier or the ammeter, the blue/brown wire from the battery is faulty.

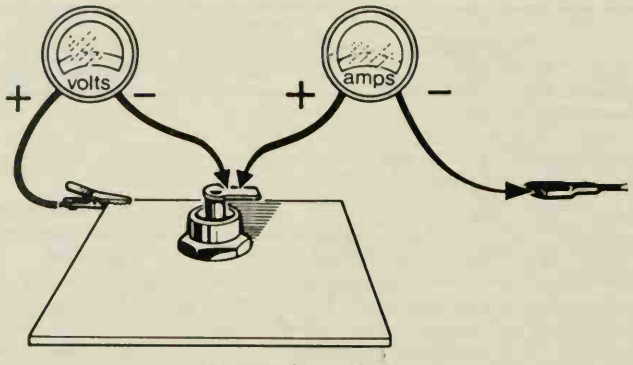
T150

Perform the charging circuit continuity test for the Trident in the same manner as described for the 500 and 650 twins.

TR7V, T150V, T150V

The test is similar to that for the 500 and 650 Twins as described above except that the wire color codes have changed. The rectifier center terminal for these models is fitted with a brown/blue wire instead of the brown/white wire for the earlier models.

Load Resistor



A 1 ohm load resistor has been referred to in several steps of the charging system test procedures. This resistor is easily obtainable from a local electrical supply outlet, or can be constructed as follows:

1. Materials:

4 yards of 18, S.W.G. (0.048 in.) Nichrome wire
1 foot of flexible, heavy gauge wire
1 alligator clip
1 piece of asbestos approximately 2 in. in diameter

2. Instructions:

Fold the thin wire double and connect the heavy wire to the folded end. Connect the other end of the heavy wire to the positive terminal of a 6 volt battery. Connect a 0–10 volt DC voltmeter between the battery terminals and an ammeter between the negative terminal of the battery and the free ends of the thin wire. Make this last connection with the alligator clip. Move the clip along the two thin wires until the ammeter reading is numerically equal to the voltmeter reading. Cut the thin wires at this point and wrap them around the piece of asbestos, making sure the wires do not touch each other.

Zener diode test

Zener Diode

The zener diode serves the functions of a voltage regular, tapping off excess alternator current output and rerouting it to a heat sink. It is very important that the diode be kept clean and free from obstruction in the cooling airstream at all times. Other than this, if you make sure that the base of the diode and heat sink have firm metal-to-metal contact, the diode is a maintenance free item.

NOTE: *Before making any of the fol-*

lowing tests, make sure the battery is in a full state of charge.

1. Disconnect the zener diode cable and connect a 0–5 amp (minimum) ammeter in series between the diode connector and the disconnected cable. The ammeter positive lead must be connected to the diode terminal.

2. Connect a DC voltmeter between the zener diode and the heat sink. The red or positive lead of the voltmeter must be connected to the heat sink, which is grounded to the frame.

3. Make sure all lights are off, then start the engine and slowly increase its speed while observing both meters.

4. Until the voltmeter reaches 12.75 volts, the ammeter should read zero.

5. Continue increasing the engine speed until the ammeter reads 2.0 amps, at which time the voltmeter should be reading 13.5 to 15.3 volts.

6. If the ammeter registers before the voltmeter reaches 12.75 volts in step 4, or if the voltage is higher than stated in step 5 when the ammeter reads 2.0 amps, the zener diode should be replaced.

CAPACITOR IGNITION SYSTEM

A capacitor ignition system kit is available to make it possible to run the machine without a battery. The kit consists only of a mounting spring and the capacitor unit itself. The system uses the same equipment as the coil ignition/battery type, with the exception of the battery.

In operation, the capacitor stores the current from the alternator and releases it at the moment of contact breaker opening. This produces an adequate spark for starting, although not as healthy a spark as it produced by a battery. When running, the capacitor also helps to reduce DC voltage ripple. The lighting system will also operate normally, except that the parking light will not function when the engine is not running.

In addition to the obvious advantage of not requiring a battery, this system has several other points in its favor: cold weather does not affect the capacitor mounted so that it can be connected in an emergency starting situation.

INSTALLATION

1. The capacitor terminals can be identified s follows:

Single terminal—positive (ground) marked with a red dot on the mounting rivet. Double terminal—negative.

2. Install the capacitor in its spring with the terminals facing down. Push the unit into the spring until the last coils fit into the capacitor body groove.

3. Connect the capacitor negative terminal *and* zener diode to the center (brown/white lead) connector of the rectifier.

4. Connect the positive terminal of the capacitor to the rectifier center ground bolt terminal.

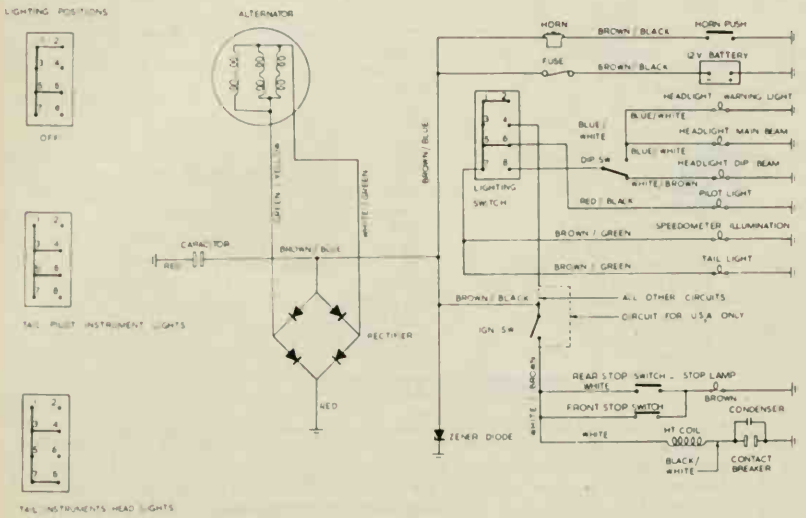
5. Mount the capacitor spring in any convenient spot near the battery carrier.

Before putting the machine into operation, a few precautions should be taken to avoid any damage to the capacitor or wiring system.

1. If the battery is to remain in the machine, it is essential that the negative lead be very carefully insulated to prevent it from shorting to the frame. This can be done by either wrapping the lead in electrical tape or, better yet, by replacing the battery fuse with a wooden dowel of similar dimensions.

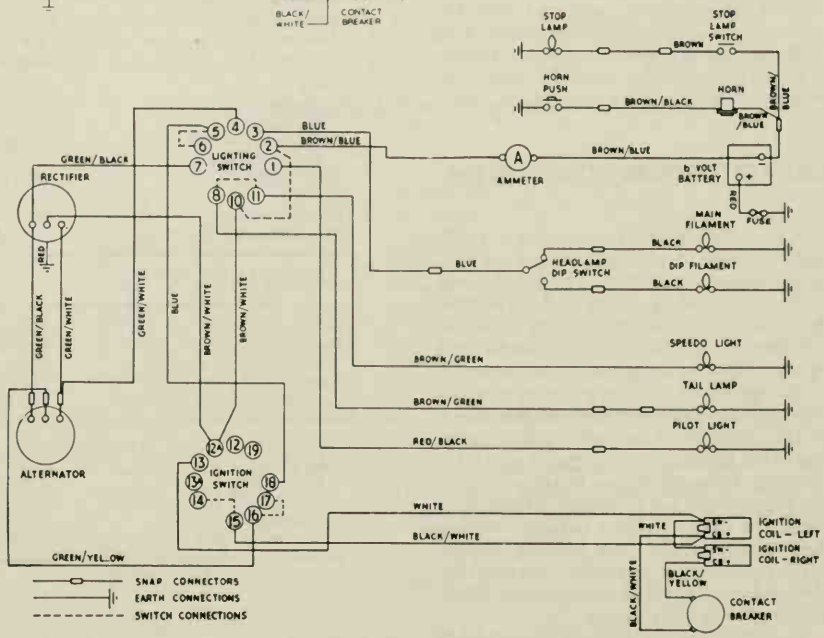
2. If the capacitor is being used as a back-up system in case of battery failure, take the time to check it occasionally to ensure that it's still operational.

3. Do not run the engine with the zener diode disconnected as the capacitor will be destroyed due to excessive voltage.



Capacitor Ignition Test

The capacitor has a limited storage life of approximately 18 months at 68° F, or 9 to 12 months at 86° F. Therefore, it would be wise to check its condition regularly if it is not in use.



1. Connect the capacitor to a 12 volt battery for approximately 5 seconds. Make sure the terminal polarity is correct or the capacitor will be ruined.

2. Let the capacitor stand for at least 5 minutes, then connect a DC voltmeter to the terminals. Note the steady reading of the meter. A good capacitor will register at least 9 volts.

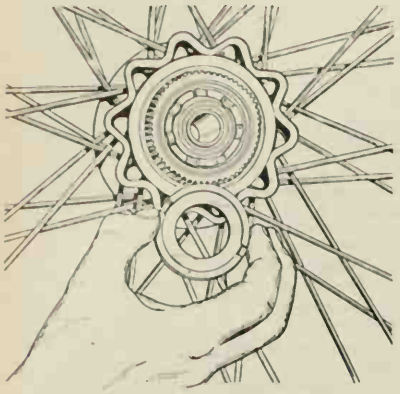
FRONT

Removal and Disassembly

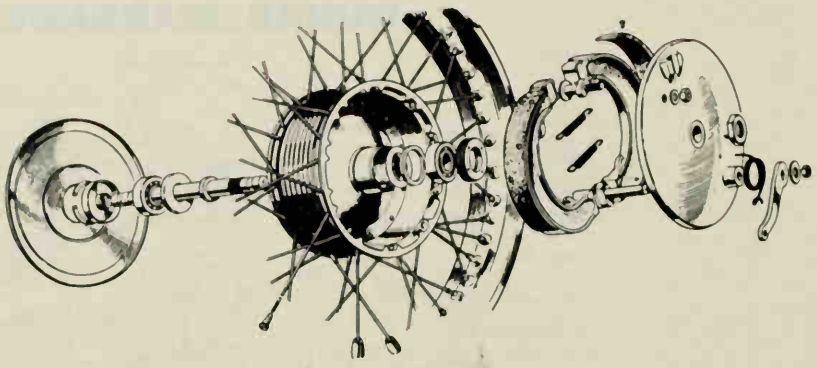
1. Support the bottom of the engine with a wooden box or wire milk basket, positioning the bike so that the front wheel is about 6 in. off the ground.

2. Loosen the front brake cable at the handlebar adjuster, then disconnect it at the brake backing plate.



3. Remove the two axle securing nuts, slide the axle through the hub, then remove the front wheel assembly.

4. Separate the front anchor plate from the wheel and remove the right retainer with Triumph special tool no. 61-3694 or a suitable substitute.



NOTE: *The retainer ring has left-hand threads.*

5. Remove the right wheel bearing by driving it out from the left side with the axle used as a drift.

6. Remove the backing ring and the inner retainer disc.

Rear wheel bearing retainer

Front wheel assembly, single-leading shoe brake

NOTE: *On machines equiped with double leading shoe brakes, the backing ring and retainer disc are replaced by a single part.*

7. Remove the left wheel bearing circlip and drive the bearing (with retaining plates) out from the right side with the axle.

8. Remove the brake backing plate center nut and withdraw the brake shoe assembly.

9. On machines equipped with double leading shoes, lift up the edge of one shoe until it is free of the backing plate. Disconnect one end of each brake return spring and then remove the second shoe. Remove the pivot pin cotter key at each end of the lever adjustment rod and lift out the pivot pin. Remove the brake cam securing nuts and washers and disconnect the return spring from the front cam. Prey off the levers one at a time and remove the brake cams.

10. On machines equipped with single leading shoes, turn the brake operating lever to relieve the pressure of the shoes against the drum, then pull out the brake and backing plate assembly. Slowly release the operating lever until the return springs can be removed, then remove the springs and the brakes shoes as shown in the accompanying illustration. Remove the operating lever securing nut and washers, then remove the lever and cam spindle.

11. Thoroughly clean all parts (except brake shoes) in kerosine or a cleaning solvent and blow them dry with compressed air.

Inspection

Examine the ball bearings for any signs of pitting or excessive wear. Replace them both if there is any doubt as to their condition.

Inspect the anchor plate for any cracks or signs of distortion, particularly in the area of the brake cam housing. Check the return springs for general condition and signs of fatigue. Measure the drum diameter in several places and check for scoring, etc. If drum diameter is 0.010 in. greater than specified, replacement is in order.

Check the condition of the brake shoes. If oil-soaked, cracked, badly scored, or if the lining is worn down to the rivets, replace the shoes.

If possible check wheel rim runout on a wheel stand. Tighten any loose spokes.

Assembly and Installation

1. On machines with single leading shoes, install the operating lever, cam spindle, and pivot pin. Fasten the return springs to their respective hooks on the brake shoes, then position the shoes over the cam and pivot pin. Snap the shoes in place by pressing on the outer edges of the shoes. Position the operating lever in a counterclockwise location then connect the return spring.

2. On machines with double leading shoes, first lubricate the spindles lightly, then install both cams—wedge shape out. Install the outside return spring on the front cam, then reinstall both brake cam levers and secure them with washers and nuts. Install the abutment plates on the anchor plate the tag side toward the anchor plate. Position the shoes with the radiused end toward the pivot pin and connect the return springs. This is most easily accomplished by installing one shoe, connecting the springs, and snapping the other shoe into place.

3. Coat the wheel bearings and retainers liberally with the recommended grease, then install the left inner retainer, bearing, and outer dust cap. Install the retaining circlip and then drive the bearing up against the circlip, using the shouldered end of the axle as a drift.

4. Install the right retainer disc and backing ring (one piece on machines with double leading brakes).

5. Using the shouldered end of the axle as a drift, drive the right bearing into place, then install the left-hand thread retainer ring.

6. The remainder of the assembly and installation procedure is a reversal of the removal and disassembly instructions.

7. Adjust the front brake.

Removal and Disassembly

1. Disconnect the speedometer drive cable, then remove the securing nut and the rear axle.

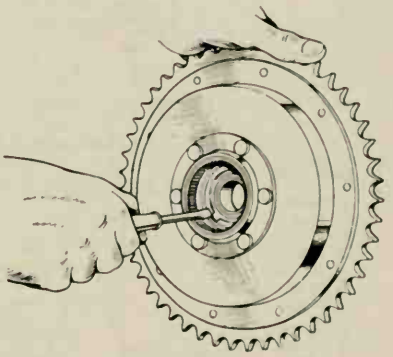
2. The distance collar that fits between the hub and the swing arm should drop out when the axle is removed, thereby facilitating wheel removal.

3. Remove the speedometer drive unit and unscrew the end cover.

4. Withdraw the wheel, leaving the brake hub assembly fastened to the swing arm.

5. Remove the left side bearing retainer.

NOTE: *This bearing retainer has lefthand threads.*



6. Using a drift slightly under ¾ in. diameter, drive out the hollow hub spindle. This will release the right bearing, inner collar, and washers.

7. Drive out the left bearing and thrust washer from the right side. Do not disturb the bearing oil seal unless it must be replaced.

8. To remove the brake hub assembly from the swing arm, disconnect the final drive chain and unscrew the brake adjusting rod sleeve. Remove the axle nut and disconnect the torque arm at the hub. Lift out the brake assembly.

9. The brake assembly can now be disassembled and inspected as previously described for the front brakes.

10. To remove the brake hub bearing, first drive out the hollow spindle from the left side and remove the bearing circlip. The bearing can then be driven out with a suitable drift.

Removing the rear hub bearing circlip

11. Do not disturb the chain sprocket unless it must be replaced. To remove it, bend back the locking tabs and remove the six securing bolts.

12. Thoroughly clean all parts (except brake shoes) in solvent and blow them dry with compressed air. *Do not spin the bearings until they have been completely dried and lubricated.*

Inspection

Examine all parts as previously described for the front wheel and hub. Replace the chain sprocket if the teeth points have become hooked or rounded.

Assembly and Installation

1. Assemble the brake hub in reverse order of disassembly. Liberally grease the bearings. Be sure to install the steel washer that fits between the bearing and circlip, otherwise the bearing will not seat properly.

2. Install the hub assembly, complete with brake shoes, etc., on the swing arm. Readjust the final drive chain.

3. Assemble the wheel hub in reverse order of disassembly. Liberally grease the bearings. Note that the bearings should be driven in place by applying pressure to the outer race only. Install the hollow spindle with the short end on the left-hand side, and install the bearing seals facing outward.

4. Install all the wheel and hub assembly in the reverse of the removal procedure. Do not forget the distance collar between the swing arm and hub. If the brake hub assembly was not removed, it will not be necessary to readjust the chain.

T100C, T100R, TR6R, TR6C, and T120R

FRONT

The front wheel assembly on the 500 and 650 cc models is basically the same as the arrangement used on the TR25W. It can be serviced in the same manner, except that on 500s, Triumph special tool no. Z76 must be used to remove the left bearing retainer ring, rather than tool no. 61-3694.

Use the accompanying illustrations for refrence.

REAR

NOTE: *The 500 and 650 cc models are equipped with either standard or quickly detachable rear wheels.*

Removal and Disassembly (Standard)

1. Disconnect the rear brake adjuster and the final drive chain.

2. Loosen the front securing bolt and swing the chainguard up out of the way.

3. Disconnect the torque arm at the hub.

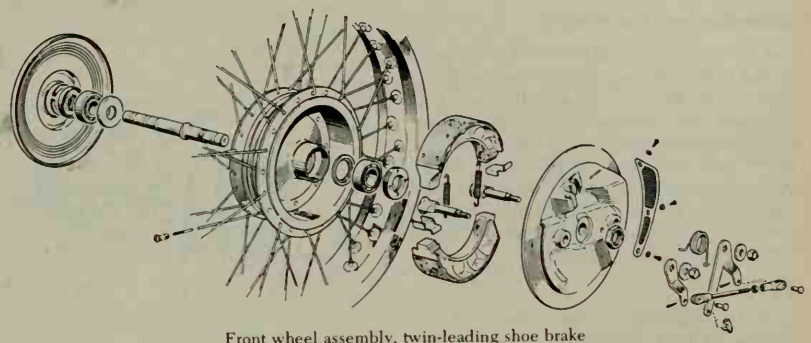
4. Disconnect the speedometer cable.

5. Loosen the axle nuts and slide off the wheel assembly.

6. Unscrew the backing plate retaining nut and withdraw the brake assembly. Service the brake assembly as described in the TR25W section.

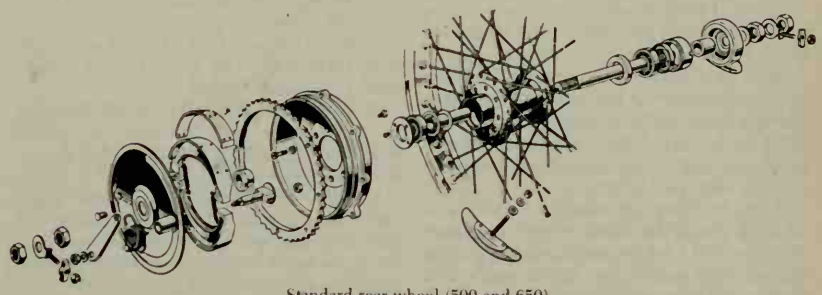
7. Remove the wheel spindle, complete with speedometer drive, out of the right side.

8. Remove the slotted screw that locks the left bearing retainer ring in place.



9. Remove the retainer ring with tool no. 276 or a suitable substitute. The ring has left-hand threads.

10. To gain access to remove the left bearing, drive the central distance piece from the left side until the grease retainer collapses. The bearing can now be driven out from the right side, using a suitable, soft drift.



11. Remove the backing ring, collapsed grease retainer and central distance piece.

12. Drive out the right bearing and dust cap with a drift approximately 1⅝ in. in diameter.

13. Thoroughly clean all parts (except brake shoes) in kerosine or cleaning solvent and blow them dry with compressed air.

Front wheel assembly, twin-leading shoe brake

Standard rear wheel (500 and 650)

Inspection

Examine all parts carefully as described in the TR25W section.

Assembly and Installation

1. Liberally grease the bearings and retainers.

2. Drive in the right grease retainer (new or straightened) and bearing. Install the dust cap after making sure that the bearing and the cavities on either side of the bearing are filled with grease.

3. Install the distance piece, right grease retainer and right bearing. Make sure everything is well packed in grease.

4. Bring the distance piece in line with the axle, then install the threaded (left-hand) retainer ring.

5. Install the retainer locking screw.

6. The remainder of the assembly and installation procedure is a reversal of the removal and disassembly instructions.

Removal and Disassembly (Quickly Detachable)

1. Disconnect the speedometer cable.

2. Unscrew the axle from the right side of the machine and pull out the distance collar.

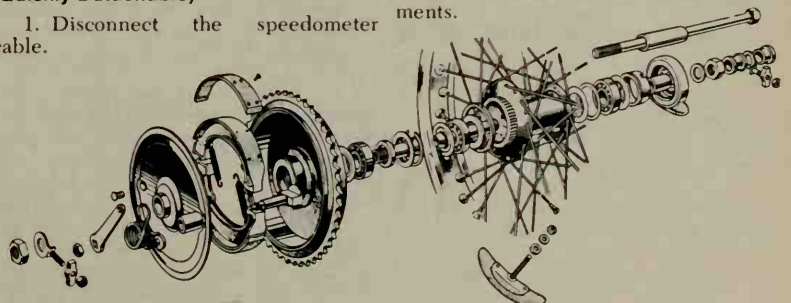
3. Pull the wheel clear of the engaging splines and remove it out the back of the machine.

4. Remove the locknut on the right side of the axle sleeve and lift off the speedometer drive unit.

5. Disassemble the wheel hub and bearings as previously described for the standard rear wheel.

6. Disconnect the final drive chain, brake operating rod and torque arm, and then remove the axle sleeve nut.

7. Disassemble the brake components as previously described in the TR25W section.



8. Press out the axle sleeve, then remove the bearing circlip located in the brake drum.

9. Pry out the retainer and felt washer, then drive out the bearing with a suitable drift.

10. Thoroughly clean all metal parts in kerosine or cleaning solvent, then blow them dry with compressed air. *Do not spin the bearings until they have been completely dried and lubricated.*

Inspection

Examine all parts as previously described and make any necessary replacements.

Quickly detachable rear wheel (500 and 650)

Assembly and Installation

Assembly and installation is a reversal of the removal and disassembly instructions. If brake work was performed and the hub was removed from the swing arm, it will be necessary to adjust the rear brake and the final drive chain. Make sure the bearings and retainers are thoroughly packed with grease and remember to soak the felt washer in oil before reassembly.

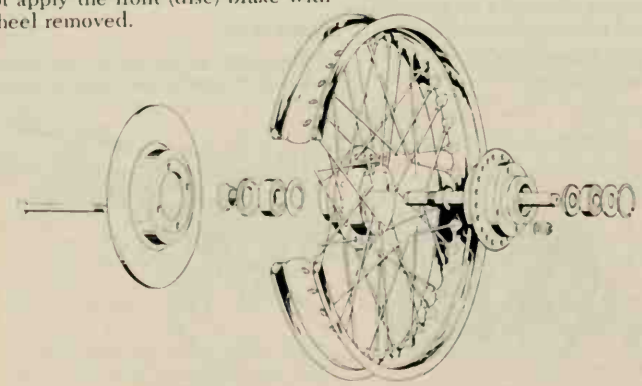
T150

Early models use a front hub not dissimilar to that described above for the TR25W. These models also used a rear hub like that of the 650 Twins (standard hub). Refer to the section above.

Note that some later model Tridents are equipped with the newer type forks (without external fork springs or fork gaitors), and these forks have four nuts on each axle cap which must be removed to remove the front wheel.

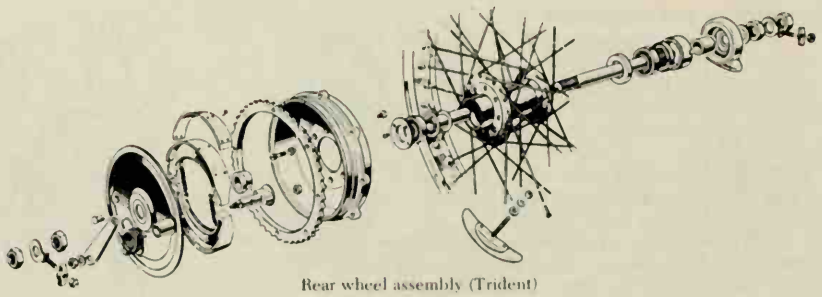
When refitting the wheel with this type of fork, place the front wheel assembly into the forks while engaging the brake anchor stud in the slot in the right fork slider. Refit the axle caps and replace all of the cap nuts, tightening them evenly until they are just a bit more than hand tight. Slacken all of them ½ turn.

Pull the wheel to the right side of the machine until the brake anchor plate facing boss touches the mating lug on the fork leg. Holding the wheel in this position, tighten the axle cap nuts *evenly* to 15 ft lbs. Check that no gap exists between the facing boss and the fork slider. Retighten the anchor stud nut.



TR7V, T140V, T150V

FRONT



Removal and Disassembly

These models are equipped with a front disc brake and the latest type of front fork. This fork is easily distinguished from earlier units in that it is *not* fitted with either external fork springs or fork gaitors. The fork tubes are chromed, and the top of each slider is fitted with a small dust seal.

1. Support the machine so that the front wheel is off of the ground.
2. Remove the four axle cap nuts at the bottom of each fork leg, remove the caps, and take away the front wheel assembly. Do not apply the front (disc) brake with the wheel removed.

Front wheel assembly (disc brake)

Rear wheel assembly (Trident)

3. Remove the axle nut on the left side, then unscrew the bearing retainer ring with the Triumph tool 61-3694 or a suitable substitute. The retainer has a standard right-hand thread.
4. Remove the left side wheel bearing by driving the axle through the wheel from the right side. Remove the grease seal beneath the bearings.
5. Take off the circlip on the right hand side of the wheel, and insert the axle into the left hand side, driving out the right hand bearing along with its two grease seals (one on each side of the bearing).

Inspection

1. Clean all parts thoroughly in a solvent and blow them dry.
2. Check the bearings for wear, pitting, play in the bearing races, and rough or uneven rotation. Replace as necessary.

Assembly and Installation

1. Refit the inner grease seal for the right side wheel bearing. Lubricate the bearing thoroughly and refit it and the outer grease seal.
2. Replace the circlip for the right side bearing. Insert the shouldered end of the axle into the left side of the wheel, and use it to drift the bearing assembly up aginast the circlip.
3. Take out the axle, and then reinsert it into the wheel from the left in its normal position.
4. Replace the left-hand bearing grease seal, the lubricated bearing, and the retainer. Screw in the retainer until tight. Tap the axle from the right until the axle shoulder contacts the left side bearing. Replace the axle nut and tighten securely.
5. Engage the brake disc into the caliper and replace the fork caps. Tighten the four nuts on the left fork slider *first*, then tighten the nuts on the right slider. In both cases, tighten the nuts evenly and in an "X" pattern. Torque the cap nuts to 25 ft lbs.

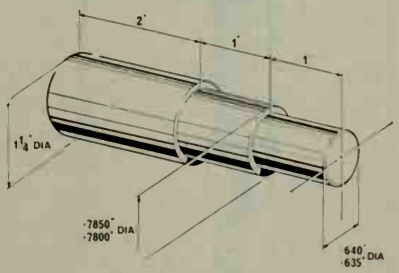
REAR

Removal and Disassembly

1. Support the machine so that the wheel is about 12 in. off the ground.
2. Disconnect the rear chain and disengage it from the rear wheel sprocket.
3. Disconnect the speedometer cable at the rear wheel. Disconnect the brake anchor at the brake plate and remove the anchor from the machine after removing the nut and bolt at the other end.
4. Loosen the bolt securing the left side shock absorber to the swing arm. Lift the chainguard so that the sprocket will clear it.
5. Loosen the axle nut (right side) and pull the wheel assembly out of the machine. Remove the axle, brake assembly, and speedometer drive.
6. To remove the bearings, remove the speedometer drive ring from the right side of the wheel.

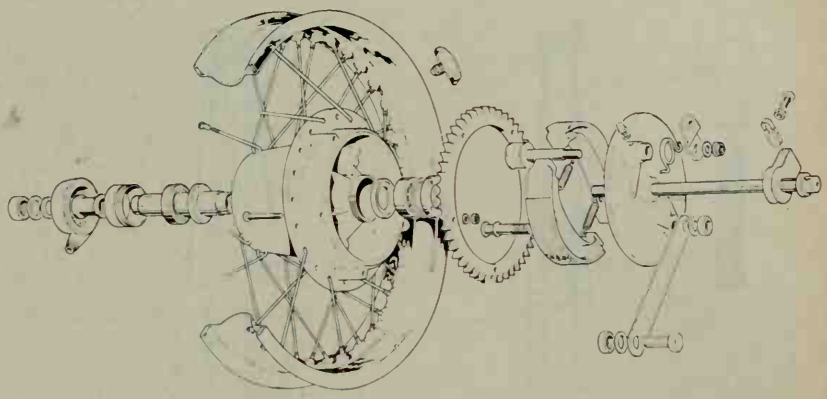
NOTE: *This ring has a left-hand thread.*

7. Remove the bearing retainer from the left side. Use Triumph tool No. 61-3694 to remove this retainer.
8. A drift is needed to remove the bearings and spacer. This drift should have dimensions as shown in the illustration. If this drift is not used, the spacer tube may be damaged, and will have to be replaced. Using the drift, insert it into either side of the wheel and knock out one of the bearings and the spacer tube out of the wheel.
9. Note that the bearing is an interference fit on the end of the spacer tube. Use the drift again to separate the bearing and the spacer tube, then reinsert the spacer tube in the hub, and use it and the drift to remove the remaining bearing. Separate this bearing from the spacer tube after removal.
10. Grease retainers behind each bearing may be left in place, but can be removed with a drift if desired by driving them out from the inside of the hub.



Inspection

1. Check the condition of the bearings and seals. If the latter have been removed, they must be replaced.
2. Wash the bearings in a solvent and blow them dry. Check for worn, dam-



aged, or pitted balls, rough rotation, and excessive play.

Assembly and Installation

1. Replace the grease retainers if they have been removed.
2. Refit one of the bearings onto the spacer tube, and place the bearing and tube into the left side of the hub. Drift the bearing into the hub until it contacts the grease retainer. When doing this, apply force to the outer bearing race only.
3. Replace the washers and the left side retainer ring and tighten it securely. Refit the other wheel bearing driving it home as with the first, and replace and tighten the speedometer drive ring (left-hand thread).
4. The remainder of the procedure is a reversal of the removal instructions.

Drift for removing rear wheel bearings (1973 and later)

Rear wheel assembly (1973 and later)

FRONT FORK

Late models (including the TR7V, T140V, an T150V) are equipped with a telescopic fork of the "slim-line" pattern easily noticeable because of its chromed fork tubes and the absence of external springs and fork gaitors.

Other models have either rod damper or shuttle valve-type forks. In general, the shuttle valve types can be identified by its longer and narrower spring, and by its overall slimmer appearance.

TR25W (Shuttle Valve Type)

REMOVAL

1. Drain the fork oil.
2. Remove the front wheel and fender.
3. Slide the boots clear of the top fork shrouds.
4. Remove the fork leg caps along with cable brackets.
5. Loosen the bottom yoke, fork pinch-bolts and screw Triumph special tool no. 61-3824 or a suitable substitute into the top of the fork stanchion.
6. Hit the tool sharply with a mallet and the stanchion taper will be freed of the top yoke.
7. The fork legs can now be removed.
8. After removing the fork legs, lift off the boots and main springs.

DISASSEMBLY

1. Wrap a piece of rubber around the fork leg and clamp the leg in a soft-jawed vise.
2. Remove the oil seal holder, using Triumph special tool no. 61-6017 or a suitable substitute. Turn the tool counterclockwise.
3. Firmly grasp the stanchion tube and move it back and forth against the top bushing until the bushing is driven out of the lower fork leg. At this time, the stanchion, complete with bushings and shuttle valve, can be removed.
4. To free the shuttle valve, remove the bottom retaining circlip, and let the valve slide out the top end of the stanchion.
5. Do not disturb the bottom bushing unless it is to be replaced. If it is, then remove the bottom bearing retaining nut and drive the bushing out with a hammer and chisel. Take care not to slip and damage the stanchion tube.
6. If it is necessary to remove the restricter at the bottom of the leg, unscrew the bolt in the spindle cutaway.
7. To remove the oil seals from their holders, take out the loose backing washer from the threaded end of the holder, and drive the seal out through the exposed slot. Note the O-ring in the threaded end of the seal holder.

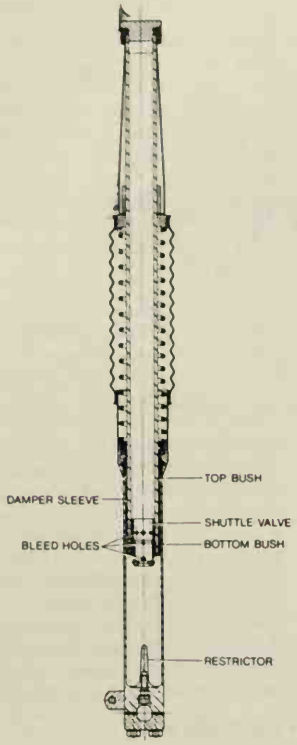
INSPECTION

1. Check the stanchion tubes for straightness by rolling them along a known flat surface. Any bow greater than 5/32 in. requires that the stanchion be replaced. If less than 5/32 in., the stanchion may be straightened.
2. Examine the top fork yoke for cracks and then insert the fork legs (if true) and tighten them down with the top caps. Take several measurements to ensure that the legs are parallel to each other and perpendicular to the top yoke. Check the bottom yoke in the same manner, but make sure at least 6½ in. of the fork legs protrude above the yoke. The bottom yoke is made of malleable metal and, therefore, can be quite easily straightened if need be.
3. Examine the bottom fork legs for any damage. Insert the stanchion tubes (with new bottom bushing) and note the amount of free-play of the bushing within the bores of the bottom legs. If excessive, or any restriction of movement is noted, the bottom legs should be replaced.
4. Check bottom fork leg and front axle alignment by installing the axle and measuring their inclusive angle with a square. Check one leg at a time, then both simultaneously.
5. Inspect the condition of the top and bottom bushings, and measure their inside or outside diameters (see specifications). Excessive wear, or too great a clearance between the bushing and its mating surface, indicates that the bushings should be replaced.
6. Check the main springs for any stress cracks etc., and measure its free-standing height. Both springs must be within ¼ in. of their original dimension.

ASSEMBLY

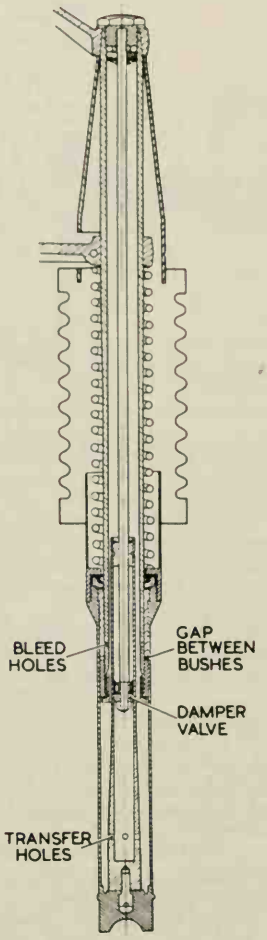
Assembly is basically a reversal of the disassembly procedure. Note the following:

1. Make sure the new bottom bushing is correctly seated before installing the retaining nut.
2. Note that the large end of the shuttle valve fits into the stanchion.
3. Thoroughly lubricate all parts in the fork before reassembly.
4. Replace the oil seals and apply locking compound to the holder threads.

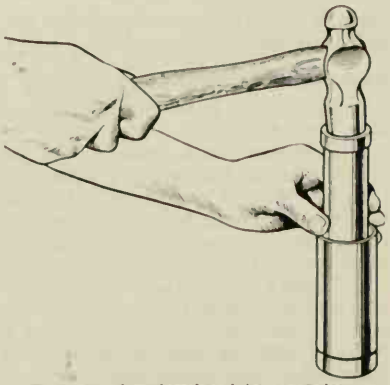


INSTALLATION

1. Slide the fork leg boots over the oil seal holders and install the main springs.
2. Insert one leg through the bottom and top yoke bores and install Triumph special tool no. 61-3824 on the top of the stanchion. Install the collar and nut, and tighten the nut until the stanchion is firmly locked in its taper.
3. Tighten the bottom yoke pinch bolts and then remove the special tool.
4. Slide the top of the fork boot over the shroud and secure it in place.
5. Repeat the previous steps for the remaining fork leg.
6. Install the front wheel and fender.

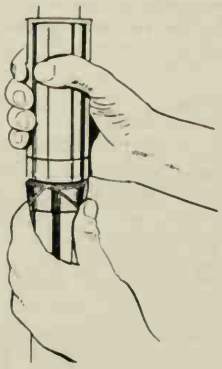


TR25W (Rod Damper Type)



REMOVAL

1. Drain the fork oil.
2. Remove the front wheel and fender.
3. Slide the fork boots off the top shrouds and loosen the bottom yoke pinch bolts.
4. Unscrew the fork leg caps and raise them high enough to loosen the damper rod locknut.
5. Remove the fork leg caps from the top of the rod damper.
6. Install Triumph special tool no.



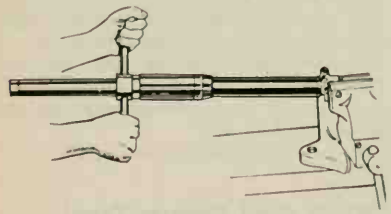
Rod-damper forks

Removing the oil seal (rod-damper forks)

Installing twine for added protection (rod-damper forks)

61-3350 or a suitable substitute into the top of one fork leg.

7. Hold the bottom of the fork leg firmly, then strike the special tool sharply with a mallet. This will free the fork leg from its taper in the top yoke.



8. Remove the other fork leg in the same manner.

9. Remove the fork boots and main springs.

DISASSEMBLY

1. Clamp the fork leg in a soft-jawed vise at the axle lug.

2. Slide Triumph special tool no. 61-3005 over the main tube and engage the dogs at the bottom of the oil seal holder.

Removing the oil seal holder (rod-damper forks)

3. While applying pressure to the end of the tool, turn it counterclockwise and free the seal holder.

4. Remove the special tool and slide the seal holder to the end of the tube. Do not attempt to entirely remove the seal holder as damage may result.

5. The main tube assembly and lower sliding leg can now be separated.

6. Clamp the un-machined portion of the tube in a soft-jawed vise and remove the large nut at the base of the shaft. Remove the bushings, spacer, and oil seal assembly.

7. Remove the allen screw that secures the damper tube to the lower portion of the fork leg.

8. Remove the two circlips at the top of the damper tube. This will free the damper rod with valve and bushing.

9. Remove the nut that secures the damper valve to the rod. Do not disturb the sealing washer and special retainer located just below the nut unless they require replacement.

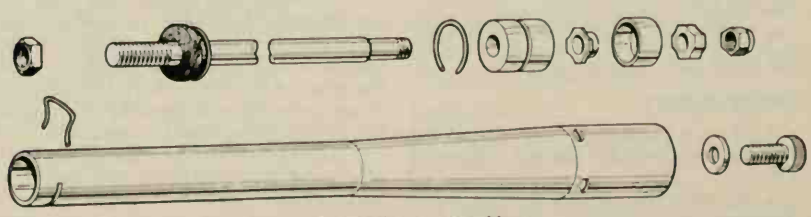
10. If an oil seal requires replacement, position the holder with the bottom edge on a wooden block and drive out the seal with Triumph special tool no. 61-3007 or a suitable substitute.

INSPECTION

Examine all parts as generally described for the shuttle-valve-type fork. Compare measurements with those given in specifications at the end of this section and made any necessary replacements.

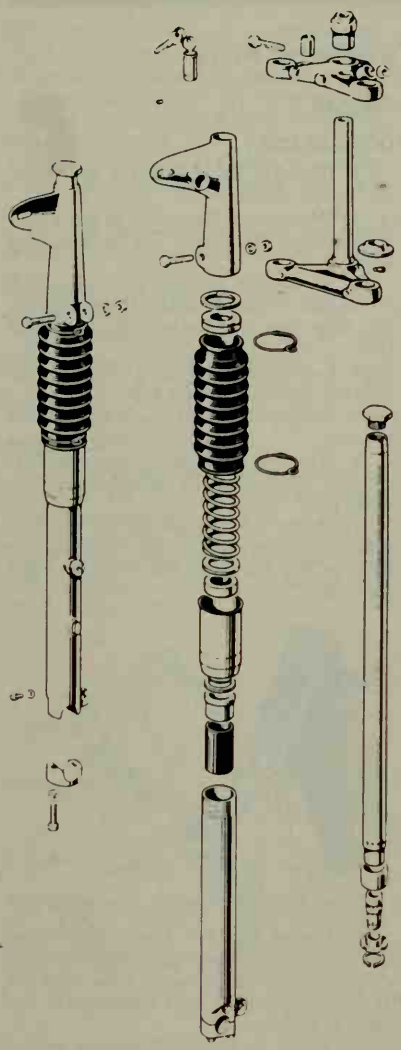
ASSEMBLY AND INSTALLATION

1. Coat the outside of the oil replacement seals with gasket sealer and drive them into their holders with Triumph special tool no. 61-3007 or a suitable substitute. Grease the feather edge of the seal before further assembly.



2. Make certain all parts are completely clean, then reassemble the remaining parts in reverse order of disassembly.

NOTE: *When tightening down the oil seal holders, it's a good idea to wrap a piece of no. 5 twine around one of the last threads. This will provide additional protection for the seals.*



3. Triumph special tool no. 61-3350 must be used to set the fork leg in its taper, and special tool no. 61-3765 must be used to raise the damper high enough in the tube to screw on the fork leg cap.

T100C, T100R, TR6R, T120R, and T150

These machines are equipped with fork assemblies nearly, if not exactly, identical to those used on the TR25W.

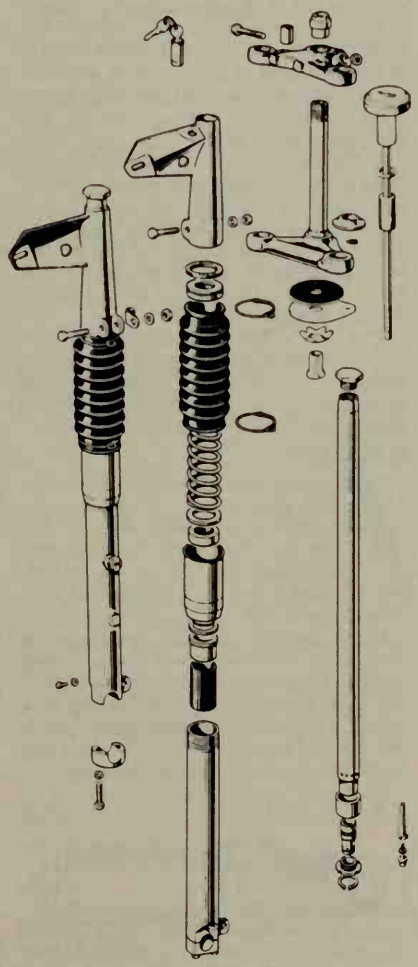
Rod and damper assembly

500 and 650 front forks

Disassembly, inspection, and assembly procedures remain the same, but the removal and installation instructions vary slightly to suit various instrument arrangements and the use of a steering damper.

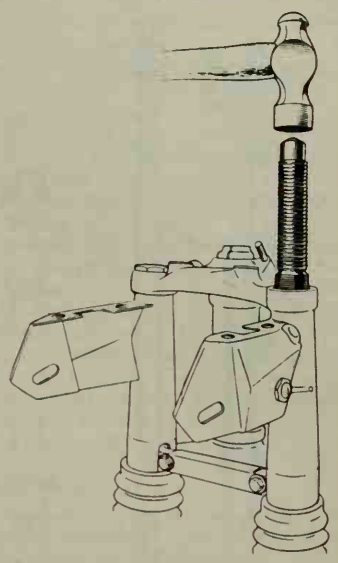
NOTE: *Some late models 650 Twins and Tridents may use the "slim-line" forks. See below.*

REMOVAL AND INSTALLATION



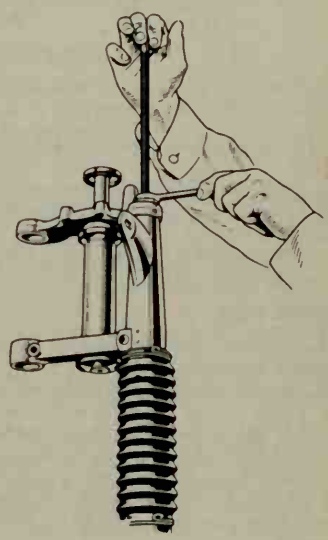
1. Drain the fork oil.
2. Remove the front wheel and fender.
3. Remove the headlight assembly.
4. Disconnect throttle, choke, and front brake cables.
5. Disconnect any instrument and/or diode wiring.
6. Remove the steering damper knob and loosen the top yoke pinch bolt. Unscrew the sleeve nuts.
7. On 500 models, also remove the steering damper anchor plate at the bottom of the frame head.
8. Remove the handlebar mounting bolts and swing the handlebar out of the way. It may or may not be necessary to disconnect all controls.
9. Hold on to the fork and then give the underside of the top yoke a good swat with a mallet. This should free the fork legs for further disassembly.
10. Installation is a reversal of the removal procedure. Special tool no. Z161 must be used to seat the fork leg in its top yoke taper on 500 cc models; tool no. 61-3824 on 650 and 750 cc models.

TR7V, T140V, T150V



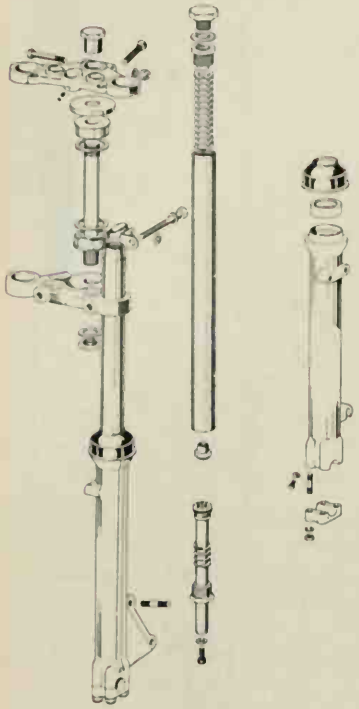
This type of fork may also be found on some 4-speed Tridents and 650 Twins.

REMOVAL AND DISASSEMBLY



1. Before beginning work on the forks, it is advisable to have two fork slider oil seals, two damper valve oil seals as well as Triumph tool 61-6113. This tool is quite necessary to the disassembly procedure.
2. Drain the forks, remove the front wheel as previously described, remove the front fender.
3. Remove the handlebars by unscrewing the two self-locking nuts which secure the handlebar clamps to the fork crown.
4. Remove the fork tube cap nuts. Disconnect the instrument cables and lights, and put them in a safe place.
5. Disconnect the hydraulic brake line at the lower triple clamp and at the fork slider.

Trident front fork assembly



Removing the fork leg stanchion

Installing the fork leg with toll no. Z161

6. Remove the caliper and put it in a safe place.
7. Loosen the pinch bolts (allen head) at the back of each fork fitting in the fork crown.
8. With an allen wrench, remove the cap screws from each fork tube, and lift out the fork springs.
9. Use special tool No. 61-6113 inserted down into the fork tube to hold the damper valve assembly in place while the allen bolt is removed from the bottom of the slider.
10. Remove the slider from the fork tube. Remove the fork tubes from the triple clamps by first loosening the pinch bolts on the lower triple clamp and yanking down on the tubes until free.
11. Lift the rubber dust cover off of the top of the slider. Remove the nut at the bottom of the damper assembly.
12. Take out the damper assembly. The damper assembly should not be taken apart unless absolutely necessary.

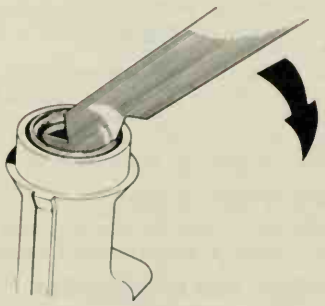
Late model "slim-line" front forks

The O-ring oil seal on the damper bleed valve should be removed and a new one fitted by hand.

13. Account for the sealing washer at the very bottom of each fork slider.

INSPECTION

1. Check all parts for wear or damage. Replace as necessary.



2. To replace the fork slider oil seal, use a tool similar to the one shown or a suitable substitute. The important thing is that the soft aluminum of the slider not be touched by the tool when removing the oil seal. Pry all around the circumference of the seal, gradually lifting it off its seat.

3. To replace the seal, cover the top of the fork tube with a thin plastic "sandwich bag" or something similar. Oil the lips of the seal, and slide it down over the top of the fork tube. Be very careful that the seal is not forced in any way. It is extremely easy to damage the seal.

Place the fork slider in position at the bottom of the fork tube, and bring the seal down to meet it.

A drift is needed to properly seat the oil seal in the slider or it will leak. After installation, remove the slider from the fork tube.

4. Clean all components thoroughly before reassembly.

Removing the slider oil seal

ASSEMBLY AND INSTALLATION

1. Refit the damper valve assembly into the bottom of the fork leg. Use a bit of thread locking compound on the damper retainer nut and tighten the nut to 25 ft lbs.

2. Locate the small sealing washer in the very bottom of the fork slider. Replace the dust cover atop the slider, and replace the slider on the fork leg.

3. Bring the slider up to meet the damper assembly and insure that the end of the damper rests on top of the sealing washer. Replace and tighten the allen screw in the bottom of the fork slider with the aid of the special tool.

4. Replace the fork leg assembly in the triple clamps. Push upward until the top of the fork tube is exactly flush with the top of the fork crown. Tighten the pinch bolts on the lower triple clamp and the fork crown to 20 ft lbs.

5. Replace the fork springs. Refill each leg with the correct grade and quantity of oil.

6. Smear the threads of the cap screws with a gasket compound, and tighten the screws to 40 ft lbs. Replace the instruments and the fork cap nuts. Tighten them to 40 ft lbs as well.

7. The remainder of the assembly procedure is the reverse of disassembly. Refer to "Front Wheel Installation" if necessary. Remember that the axle cap nuts on the left slider are tightened first.

ALIGNMENT

In the event that the fork alignment is not correct, loosen the axle cap nuts on the left slider, and tighten those on the right. Loosen the pinch bolts on the lower triple and the fork crown, including the pinch bolt just behind the fork crown center nut.

Pump the forks up and down several times and then retighten the axle cap nuts, the lower triple clamp pinch bolts, the fork crown pinch bolts at the fork tubes, and finally the fork crown pinch bolt behind the center nut. The nuts and bolts must be tightened in that order.

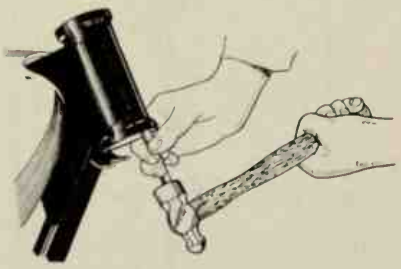
STEERING HEAD

TR25W

DISASSEMBLY

1. Remove the headlight assembly and speedometer head.

2. Disconnect the front brake cable and remove the zener diode and heat sink.



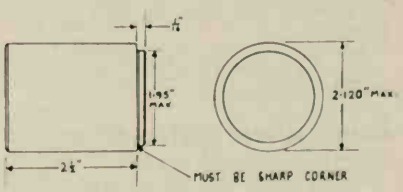
3. Protect the gas tank with a piece of cloth, then remove the handlebar mounting bolts and lay the handlebar on the tank.

4. Loosen the steering head clamp bolt and top yoke pinch bolt.

5. Remove the steering head adjusting nut.

6. Unscrew the fork leg caps and disconnect them from the damper rod (if so equipped).

7. Strike the underside of the top yoke smartly with a mallet. This should free the fork legs from their tapers in the top yoke.



Removing the top bearing cone race

8. Locate the top yoke somewhere out of the way, then pull steering stem down and out of the head. Take care not to lose the bottom ball bearings as the stem is withdrawn.

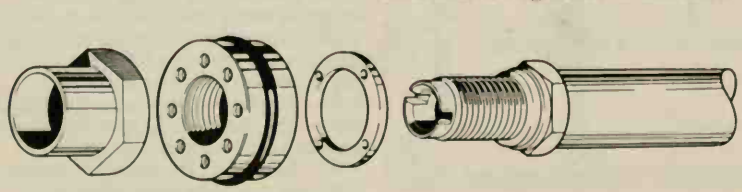
9. Drive out the top cone race with a long narrow drift and mallet.

10. Pry out the bottom cone race by forcing it up with two levers.

11. Remove the cups by installing special tool no. 61-306.

Drift for cup removal (250)

INSPECTION



Examine the bearing balls for pitting, scoring, or flat spots and, if necessary, replace the bearings, cups, and cones.

Clean out the steering head bore and remove any burrs, etc., with emery cloth. Also clean up and inspect the stem itself.

ASSEMBLY

1. Install the bearing cups by driving them into position with a drift. Make sure the cups are square in their housings.

2. Drive the bottom cone into position

Damper assembly (1973 and later)

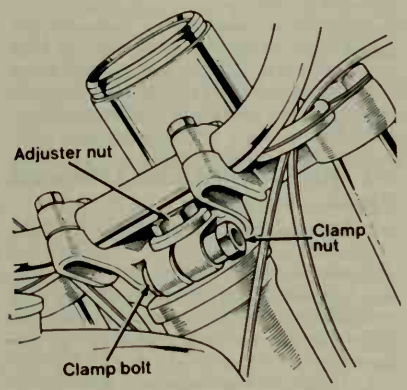
with a piece of pipe 1¼ in. in diameter and long enough to clear the column. Make sure it is squarely seated.

3. Liberally grease the bearing cups with the recommended lubricant and install the bearing balls.

NOTE: *There should be forty bearing balls all together; twenty for each race.*

4. Slide the stem back into the head and assemble the top cone and dust cover.

5. Install the top yoke and screw on the adjuster cap.



6. The remainder of assembly is a reversal of the removal procedure.

7. Adjust the steering head as described below.

ADJUSTMENT

1. Place a strong support under the engine so that the front wheel is about 6 in. off the ground.

2. Standing in front of the bike, attempt to rock the front fork back and forth. If there is any play, an adjustment will be necessary.

Steering head adjustment (250)

NOTE: *It is very difficult to distinguish between steering head play and front fork bushing wear, so a more accurate method of determining whether an adjustment is necessary is by having a helper hold the fingers of one hand on the top head bearing race while the fork is being rocked. Any play will be easily detected by the helper.*

3. Turn the fork from steering lock to steering lock. The movement should be free of any binding, etc. A "lumpy" feeling when turning the fork indicates that the bearings and races need replacement.

4. If an adjustment is necessary, loosen the steering head clamp bolt and the top yoke pinch bolt.

5. Turn the adjuster bolt until there is no rocking free-play. Make sure the bearings aren't *too* tight by centering the front fork and giving it a slight push to one side. The fork should fall freely until it reaches the steering lock.

T100C and T100R

Follow the disassembly and assembly instructions given for the TR25W, with the following exceptions:

1. When driving the bearing cones into position, use Triumph special tool no. Z24 or a piece of tubing 9 in. long with a diameter of 1 1/16 in.

2. Note that there are forty-eight bearing balls total; twenty-four in each race.

Also adjust the steering head as previously described. Adjustment is achieved by loosening a pinch bolt at the rear of the top yoke and turning the steering head sleeve nut until the bearings are at their working clearances.

TR6R, TR6C, and T120R

Follow the disassembly and assembly instructions given for the TR25W, with the following exception:

1. When installing the bearing cones, use Triumph special tool no. 61-6009 or a piece of tubing 9 in. long with a diameter of 1 1/16 in.

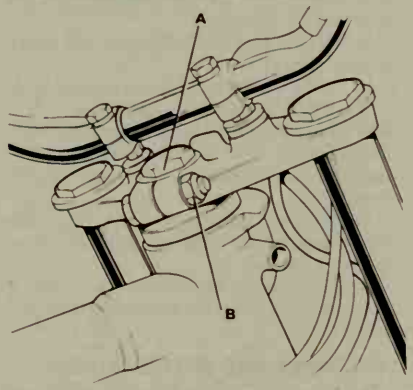
Adjust the steering head as described above for the T100C and T100R.

T150

Follow the disassembly and assembly instructions given for the TR25W, with the following exception:

1. When driving the bearing cones into position use Triumph special tool no. D2218 or a piece of tubing 9 in. long with a diameter of 1 1/16 in.

Adjust the steering head as described above for the T100C and T100R.



TR7V, T140V, T150V

DISASSEMBLY

1. Disconnect the brake line from the fork crown and lower triple clamp.

2. Disconnect the zener diode wires and remove the diode and heat sink from the machine.

3. Remove the headlight and the handlebar assembly. Remove the fork cap nuts. Place the instruments aside.

Steering head adjustment nut A and pinch bolt B (TR7V, T140V)

4. Support the machine so that the front wheel is far off the ground. Remove the front wheel and fender as described above.

5. Loosen the fork crown pinch bolt in back of the large adjuster nut, and loosen all of the pinch bolts on the fork crown and lower triple clamp.

6. Remove the fork legs from the triple clamps.

7. Remove the large adjuster nut from the fork crown and take off the fork crown while holding the lower triple clamp in place. Strike the underside of the crown with a soft-faced mallet if necessary.

8. Lower the triple clamp and steering stem from the head lug. Remove the bearings from the steering stem and the head lug.

INSPECTION

1. Clean the bearings thoroughly in a solvent and blow them dry.

2. Inspect for wear, pitting or scoring, or fractures.

3. After the barings are completely dry, lubricate them generously with bearing grease.

4. The bearing races in the head lug can be removed, if necessary, with the aid of a drift wielded from the inside of the head lug. When replacing them, note that bearing abutment rings are fitted behind the races. Use Triumph tool No. 61-6121 to refit the races.

ASSEMBLY

Assembly is the reverse of the disassembly procedure. Note that the fork tubes must be installed flush with the surface of the fork crown. The fork spring retainer nuts will stand above the fork crown.

ADJUSTMENT

Adjustment of the steering head bearings does not necessitate the removal of any components.

1. Support the front wheel off of the ground.

2. Grasp the fork sliders, and attempt to move them forward and back, noting any movements as you do so.

3. Another method, which is also recommended, is to grasp the tip of the front fender and attempt to move the fork assembly up and down. Your other hand should be positioned beneath the steering head feeling for any movement of the lower triple clamp relative to the steering head.

4. The presence of play in the forks in either of these tests would indicate that the bearings must be adjusted.

5. Also note that the forks should be able to be turned from side to side without any binding or a "lumpy" feeling. The latter may indicate worn or broken roller bearings or dented races. See section above for bearing replacement.

6. To adjust the steering head bearings, loosen the fork crown pinch bolt just behind the large bearing adjuster nut, and loosen the adjuster nut itself.

Then tighten the adjuster nut until bearing adjustment is correct. Be certain that the adjustment is not made too tight. This will be noticeable by a wobbly feeling at low road speeds, the same as though a steering damper was tightened down too much. The forks should swing from side to side very easily.

After adjusting the bearings, retighten the fork crown pinch bolt, and recheck the adjustment.

REAR SHOCK ABSORBERS

DISASEMBLY AND ASSEMBLY

The shock absorber consists of a sealed hydraulic damper unit, coil spring, dust

covers, and rubber end bushings.

1. Position the cam ring or adjusting ring in its lowest (light load) setting.
2. Clamp the bottom lug of the shock in a soft-jawed vise, then compress the spring by hand and have a helper remove the spring retaining collars.
3. If the rubber end bushings require replacement, drive them out with a suitable drift.
4. Inspect the damper unit for any signs of oil leakage, bending of the plunger rod, etc. Replace it if necessary. Examine the coil spring for any stress cracks, then measure its freestanding height and compare with specifications.
5. Assembly is a reversal of the disassembly procedure. If installing new end bushings, smear them with soapy water to aid assembly.

SWING ARM

The swing arm is mounted to the rear of the frame by a spindle supported in plain bushings. In conjunction with the rear shock absorbers, it serves as the rear wheel suspension system.

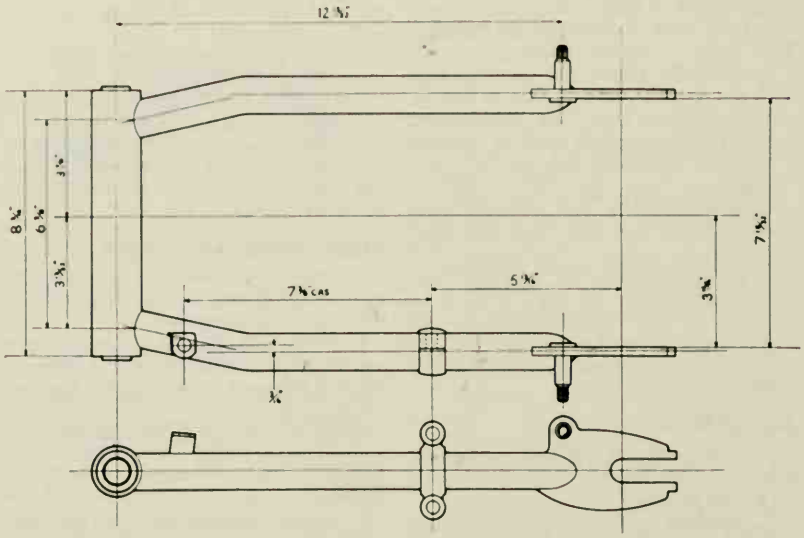
TR25W

REMOVAL AND DISASSEMBLY

1. Remove the rear wheel, chainguard, shock absorbers, and rear brake pedal.
2. Disconnect the brake light switch connectors and remove the switch with its bracket.
3. Remove the large spindle nut and washer on the right side of the machine.
4. Drive the spindle out of the swing arm bore with a suitable drift and mallet.
5. Tap the left side of the swing arm down and the right side up, using a mallet. This will free the swing arm from the frame plates.
6. Each swing arm bushing consists of two steel sleeves bonded together with rubber. The inner sleeves are slightly longer than half the width of the swing arm and are locked together, thereby putting the rubber under tension when the arm swings through its arc.

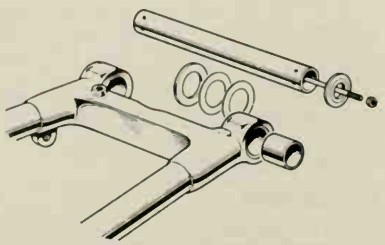
If it is necessary to replace the bushings, the rubber must first be burned out to facilitate removal. This can be done with a thin rod or strip of metal heated until cherry red.

7. When enough rubber has been removed, drive out the inner sleeves and then the outer sleeves.



ASSEMBLY AND INSTALLATION

Assembly and installation is a reversal of the removal and disassembly procedure. Do not tighten the swing arm spindle nut until after the shock absorbers have been installed.



T100C and T100R (Before Serial No. H49832)

REMOVAL AND DISASSEMBLY

1. Remove the front chainguard bolt, disconnect the stoplight switch wiring and remove the switch operating clip from the brake rod.

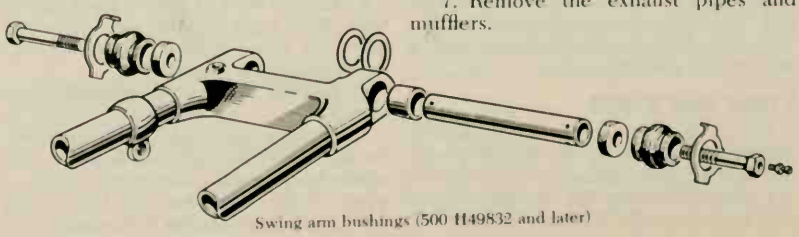
Swing arm (250)

Swing arm bushings (500 before H49832)

2. Disconnect the shock absorbers from the swing arm.
3. Remove the swing arm spindle retaining rod and caps.
4. Using a threaded extractor (see illustration), draw the spindle out the right side of the machine.
5. Disconnect the chain and rear brake torque arm.
6. Disconnect the brake operating rod.
7. Remove the rear chainguard bolt and swing the chainguard out of the way. Disconnect the speedometer cable, loosen the rear axle nuts and remove the rear wheel.
8. Remove the swing arm from the frame lugs. Take care to mark and separate the spacers.
9. Remove the swing arm bushings by driving them out with a suitable drift and mallet.

ASSEMBLY AND INSTALLATION

1. Press or drive in the new swing arm bushings. A drift can be fabricated out of 31/32 in. bar stock by machining 1 in. of one end to 7/8 in. diameter.
2. Line-ream the bushings to the bore size given in specifications, using Triumph special tool no. Z126 or a suitable substitute.
3. Assemble the swing arm to the frame lugs, using the same spacers that were removed. Lift the arm up and let it drop: the arm should just be able to move under its own weight. If movement was restricted, remove a spacer on each side and try again; if movement was too free, add spacers until the correct working clearance is obtained.



NOTE: *Spacers are available in 0.003 and 0.005 in. sizes.*

4. When the correct clearance has been obtained, grease the bushings and spindle, then press the spindle into position with the extractor tool used for removal.
5. Lubricate the swing arm grease nipple with the recommended lubricant, then assemble the remaining parts in reverse order of disassembly.

T100C and T100R (After Serial No. H49832)

REMOVAL AND DISASSEMBLY

1. Support the machine on its side stand or a wooden box, then disconnect the center stand spring.
2. Disconnect the chain and remove the rear brake adjuster.
3. Disconnect the brake torque arm from the hub.
4. Remove the rear chainguard bolt and swing the chainguard up out of the way.
5. Disconnect the speedometer cable, then remove the rear wheel.
6. Disconnect the rubber chain oiler tube.
7. Remove the exhaust pipes and mufflers.

Swing arm bushings (500 H49832 and later)

8. Disconnect the stoplight spring and wiring connectors.
9. Remove the shock absorbers and rear brake pedal, complete with operating rod.
10. Remove both rider's footpegs.
11. Remove the small, front chainguard and front. lower switch panel.
12. Remove the oil tank lower mounting nuts and tap the studs back through the mounting lug. Note the position of the distance washer that fits between the oil tank bottom bracket and frame mounting lug.
13. Remove the rear fender, front, bottom mounting bolt. Loosen the top and remove the bottom nuts and bolts that secure the front and rear part of the frame.
14. Straighten the tab lockwashers and remove both swing arm spindle end bolts.
15. Pivot the rear frame upward and support it in this position.
16. Remove both swing arm spindle distance pieces noting that the thicker one fits on the chain side.
17. Remove the swing arm spindle by tapping it out with a suitable, shouldered drift. The chain side of the spindle has an extra hole that will accept a C-wrench, should it become needed on reassembly.
18. Drive out the swing arm bushings with a suitable drift.

ASSEMBLY AND INSTALLATION

1. Install new bushings as described for the "T100C and T100R before serial no. H49832."
2. The remainder of assembly and installation is a reversal of the removal and disassembly procedure. Note that when installing the swing arm distances pieces, the ribbed sides must face the rear frame side plates.

TR6C, TR6R, T120R and T120 and T150V

REMOVAL AND DISASSEMBLY

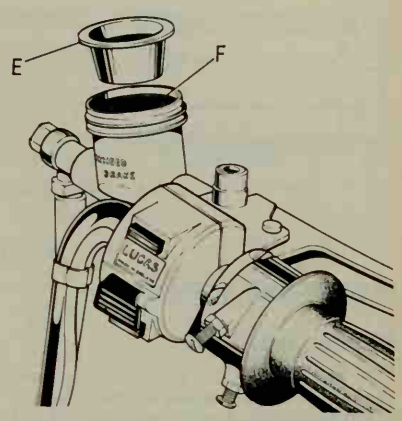
1. Disconnect the chain and rear brake torque arm, then remove the brake rod adjuster.
2. Loosen the rear axle nuts and remove the rear wheel.
3. Remove the two long and two short bolts that secure each of the rear engine mounting plates.
4. Loosen the rear chainguard bolt and remove the front chainguard bolt.
5. Disconnect the stoplight wiring connectors and remove the chainguard.
6. Remove the bottom shock absorber mounting bolts.
7. Disconnect the oil scavenge line from the oil tank for clearance, then remove the swing arm spindle locknut.
8. Unscrew the spindle until it is free to be withdrawn.
9. Remove the swing arm assembly and separate it from the end plates, outer sleeves and distance pieces.
10. Drive out the swing arm bushings with a suitable, shouldered drift.

ASSEMBLY AND INSTALLATION

1. Install new swing arm bushings as previously described for other models.
2. Thoroughly lubricate all parts with grease, then assemble them in the order shown in the accompanying illustration. Tighten the spindle bolt until the swing arm will just move under its own weight.

NOTE: *If the swing arm spindle is replaced, make sure the new one has the same thread pitch as the original.*

3. To remove any spindle side-play, it is necessary only to remove the distance sleeve and file one end to shorten the length.



TR7V, T140V

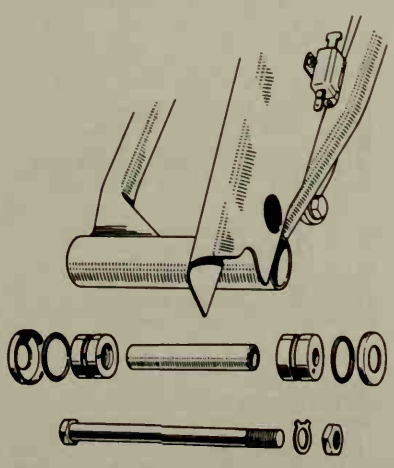
REMOVAL AND DISASSEMBLY

1. Remove the rear wheel and the chainguard. Remove the shock absorbers.
2. Remove the swing arm spindle nut on the right side and pull out the spindle.
3. Take the swing arm out of the frame.
4. Remove the four dust covers (one on each side of the swing arm bush housings).
5. Note the location of the thrust washers (the thicker of the two is fitted to the right side of the swing arm); remove the spacers.

INSPECTION

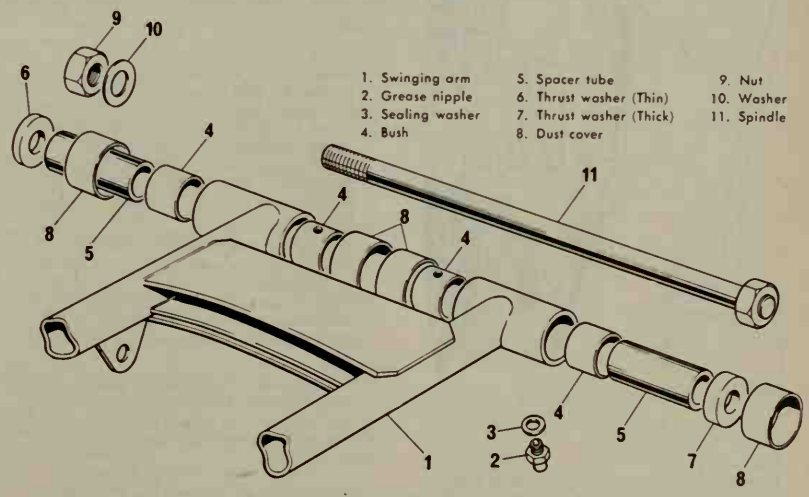
1. Clean all parts thoroughly.

Fluid reservoir diaphragm (E) and fluid level (F)



2. Check the bushes for wear or damage.
3. Check the dimensions of the bushes and spacer tubes against the standard values given at the end of this section. Replace any worn parts as is necessary.
4. A special tool (No. 61-6117) is used to remove and install the bushes in their housings. Note its operation in the accompanying illustrations. A drift can also be used, provided that it has a narrow section 1 in. in diameter and a 1⅛ in. shoulder.

Use some grease on the bushings to facilitate reassembly. Note that new bushes are pre-sized and need not be reamed to fit correctly.



ASSEMBLY

Assembly is the reverse of the disassembly procedure. Refer to the exploded diagram for the correct placement of the parts. Replace the dust covers in their proper positions, then place the swing arm in the frame. Fit the thrust washers (they are of different thickness: the thicker is fitted to the right side of the swing arm). Replace the spindle and the spindle nut.

Replace the chainguard and rear wheel.

DISC BRAKE SERVICE

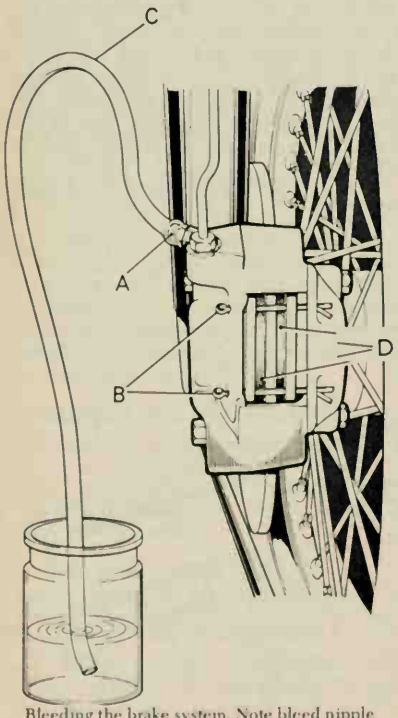
Maintenance

1. The hydraulic brake fluid level should be set at about ¼ in. from the top of the reservoir after the system has been bled. It is not necessary to add fluid to the system provided that there are no leaks in the lines. The fluid level in the reservoir will drop slightly as the brake pads wear.

2. The brake pads should be examined for wear at regular intervals. To do this, it will be necessary to remove them.

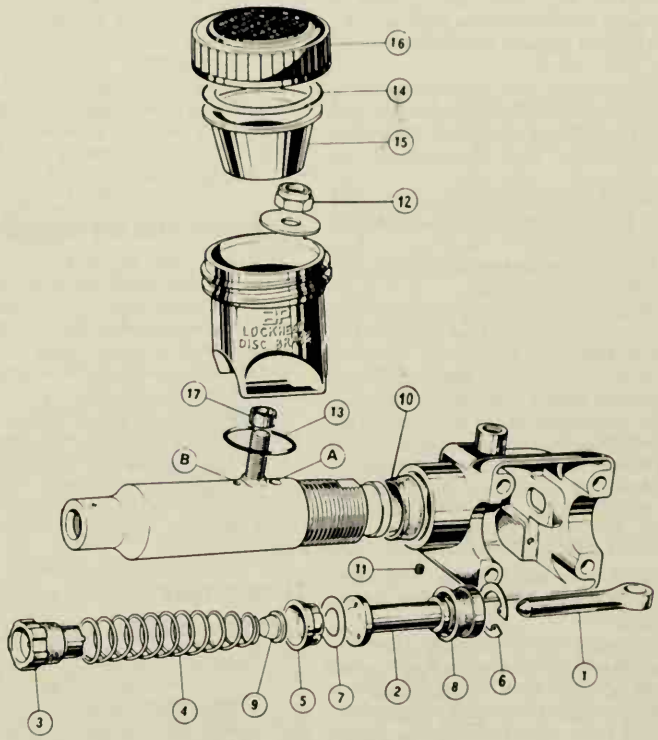
a. Remove the caliper's aluminum cover by removing the two phillips head screws.

b. Remove the two cotter pins. (These are indicated by the letter "B" in the illustration).



c. Pull out both pads.

d. Pads are bonded to the brake lining material. They must be replaced when the lining thickness is 1/16 in. (1.6 mm) or less.



e. It is recommended that new cotter pins be used upon reassembly.

Bleeding

Any time any part of the brake system has been removed or the line is disconnected, it will be necessary to "bleed"

Bleeding the brake system. Note bleed nipple (A), brake pad cotter pins (B), and brake pads (D)

the system, that is, to remove air pockets and bubbles from the system.

NOTE: *Before beginning the operation, read the following points:*

a. Brake fluid drained from the system should not be used again.

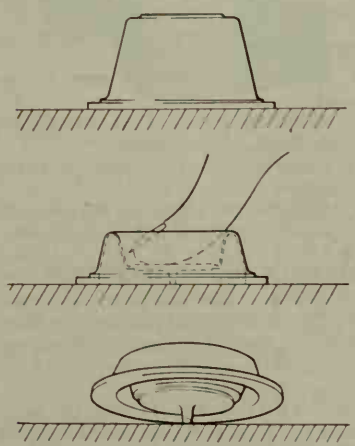
b. Insure that the master cylinder reservoir is kept at least half full during the entire bleeding operation.

c. Take all precautions necessary to insure that the brake fluid does not come in contact with any type of painted surface.

1. Refer to the illustration. Attach one end of a rubber hose to the caliper bleed nipple and immerse the other end in at least ½ in. of brake fluid contained in a jar. Note that the hose swings upward after leaving the bleed nipple. This is important.

2. Remove the fluid reservoir cap and take out the rubber diaphragm.

3. Loosen the bleed nipple from ½ to ¾ of a turn.



4. Insuring that the master cylinder reservoir is full of fluid, pull the brake lever all the way to the twist grip, holding it there for several seconds.

Note that the action of pulling the lever will force fluid and air bubbles through the hose and into the jar.

5. Release the brake lever and repeat the operation, always maintaining sufficient amount of fluid in the master cylinder, until air bubbles no longer issue from the end of the hose.

6. At this point, hold the brake lever *on*, and retighten the bleed nipple. Refill the reservoir to the proper level.

NOTE: *The correct fluid level, given as ¼ in. from the top of the master cylinder reservoir, should be maintained. It is important to remember, however, that if the brake pads in the caliper are not new when the system is bled, the fluid level will rise in the reservoir when new pads are installed. Therefore, it may be necessary to remove some fluid from the reservoir when this is done.*

Compressing diaphragm prior to installation

7. Refer to the illustrations, and fold the diaphragm, as shown, before replacing it in the master cylinder reservoir. Install the paper washer in the cap, and screw on and tighten the cap securely.

Flushing

Every three years, or if the system has accumulated any foreign matter, it should be flushed out as directed below:

1. Connect a hose to the bleed nipple, running the other end into a container, and squeeze the brake lever until all of the fluid in the system has been pumped out.
2. Fill the master cylinder reservoir with denatured alcohol and pump it out through the system in the same manner.
3. After all of the alcohol has been removed, fill the master cylinder with brake fluid, and bleed the system as described above.

Master Cylinder

REMOVAL AND DISASSEMBLY

1. Drain the brake fluid. Disconnect the brake line at the master cylinder.
2. Remove the brake lever and then the pushrod.
3. Remove the four screws which hold the master cylinder assembly on the handlebar, and remove the assembly.
4. Remove the reservoir cap, if this has not already been accomplished, and the paper washer and diaphragm.
5. Remove the nut inside the reservoir, and separate it from the master cylinder. Note the location of the spacer and O-ring beneath the reservoir.
6. Remove the set screw which locks the cylinder into the rest of the assembly, and unscrew the cylinder.
7. Remove the dust cover from the end of the cylinder. Use the pushrod, inserting it into the master cylinder, to push down the piston and remove the circlip.
8. Remove the secondary seal and piston, the piston washer, primary seal, return spring retainer, spring, and check valve. If the primary seal will not come out of the piston, try blowing into the brake line end of the piston.
9. Remove the secondary seal from the piston by stretching it over the piston flange.

INSPECTION

1. All seals and O-rings must be replaced.
2. Check the inside of the cylinder for scoring. Replace if necessary.
3. Clean all parts thoroughly in *brake fluid only.*

CAUTION: *Do not clean the parts in any sort of solvent such as gasoline.*

ASSEMBLY AND INSTALLATION

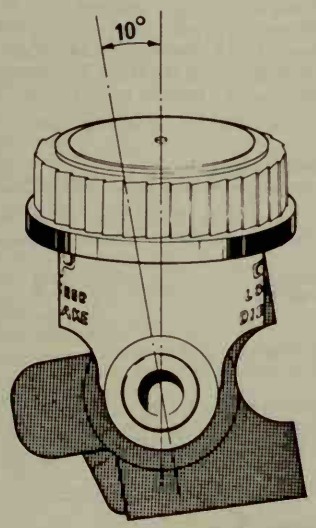
1. Fit the new secondary seal onto the piston noting that the seal lip faces the drilled end of the piston. Work the seal around the groove in the piston until it is properly seated.
2. Fit the check valve onto the large end of the return spring, and the spring retainer onto the other end. Insert the assembly into the cylinder, check valve first.
3. Fit the primary seal into the cylinder, inserting the lip end of the seal first. Do not force the seal, and make sure that the lip is not folded back upon installation.

4. Install the piston washer, convex side *outward* (towards the piston), and then the piston (drilled end piston), and then the piston (drilled end first). Depress the piston with the pushrod as on removal, and replace the circlip. Be sure the circlip is properly seated.

5. Fit the dust cover boot over the end of the cylinder.

6. Install the reservoir O-ring, spacer, and the reservoir.

7. Fill the reservoir with brake fluid, insert the pushrod into its place, and push inwards on the piston. The pushrod should be pushed in several times and then brake fluid should begin to flow out of the brake line connection at the end of the cylinder.



8. Drain the fluid.

9. The master cylinder must be properly located in the housing. Proceed as follows:

a. Remove the reservoir from the cylinder.

b. Insert the pushrod in place and install the brake lever and bolt.

c. Screw the cylinder into the housing while holding the brake lever *on* until the cylinder can no longer be turned.

Fluid reservoir installation angle

d. Refer to the exploded diagram of the master cylinder assembly. Note that the cylinder has two ports, designated "A" and "B" which flank the reservoir mounting stud. "A" is the main feed port, and "B" the breather port.

e. Place a finger over the main feed port "A" and blow through the brake line end of the cylinder. No air should escape.

f. Unscrew the cylinder while blowing through the cylinder until air just begins to escape from the breather port "B."

g. Unscrew the cylinder one full turn, and set the reservoir stud at about 10° from the vertical. This will allow the flat section on the threaded end of the cylinder to line up with the set screw.

h. Thread in the set screw and tighten it.

i. Refit the reservoir spacer, O-ring, and reservoir.

10. Install the master cylinder assembly on the handlebar and bleed the system as previously described.

Brake Caliper

REMOVAL AND DISASSEMBLY

1. Remove the caliper cover (2 screws), drain the brake fluid; disconnect the brake line from the caliper.

2. Remove the nuts which secure the caliper to the fork slider, and remove the caliper.

3. Remove the cotter pins which hold the brake pads, and remove the pads from the caliper.

4. Pry out the dust seal and the metal dust seal housing from both halves of the caliper.

5. With the aid of compressed air applied to the brake fluid inlet, eject each piston from its bore.

NOTE: *Mark each piston for location after removal. Each must be reinserted into its own bore.*

6. Pry out the fluid seals in each piston bore with a small, blunted screwdriver, being extremely careful not to damage the seal grooves.

CAUTION: *The brake caliper halves must never be separated. If this has been done, the fluid passage seal should be renewed if damaged, and the caliper mating surface and bolts thoroughly cleaned.*

Tighten the bolts to 35–40 ft lbs, and check the caliper for fluid tightness under maximum braking pressure.

The caliper should be returned to the manufacturer for an overhaul if the halves have been split.

INSPECTION

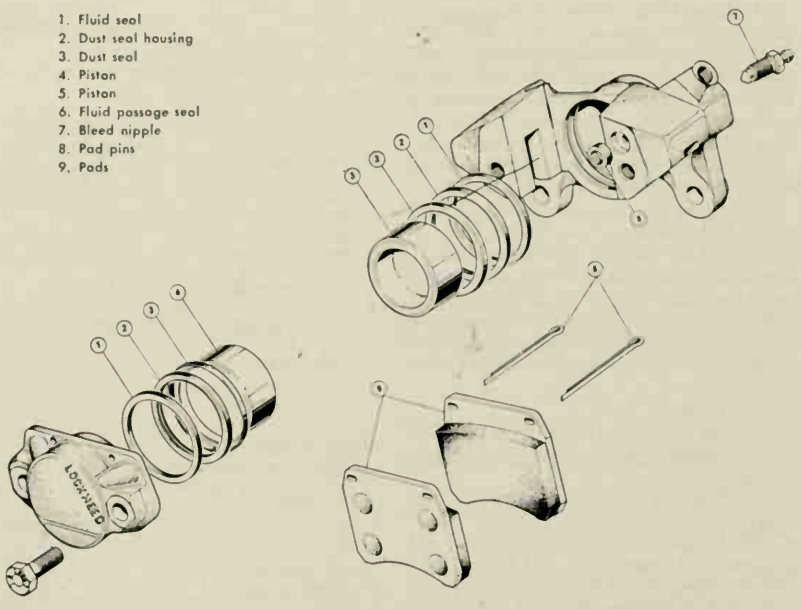
1. The dust seals and metal housings *must* be replaced.

2. The brake fluid seals must be replaced if they have been removed.

3. Inspect the pistons and piston bores for scoring or signs of seizure.

4. Clean all parts thoroughly.

ASSEMBLY AND INSTALLATION



1. Smear the fluid seals with brake fluid and replace them in their grooves in the cylinder bores. Note that the larger side faces outward, toward the open end of the bore. Be sure the seals are properly seated.

2. Coat the pistons with brake fluid, and insert each of them, closed end first, squarely into its bore. Press them in as far as possible.

3. Coat one of the dust seals with brake fluid and fit it into a metal housing. Place this assembly into one of the bores with the dust seal on the inside (facing the piston in that bore). Place a suitable shaped plate over the dust seal assembly, and use a "C" clamp to press the assembly into the bore until the outer edges of the metal housing are flush with the bore surface.

4. Repeat this procedure with the other dust seal.

1. Fluid seal
2. Dust seal housing
3. Dust seal
4. Piston
5. Piston
6. Fluid passage seal
7. Bleed nipple
8. Pad pins
9. Pads

Caliper assembly

5. Replace the brake pads, securing them with new cotter pins.

6. Secure the caliper to the fork slider, tightening the nuts securely. Reconnect the lines, and bleed the system as previously described.

Brake Disc

1. Check the disc for scoring or other damage.

2. Check for run-out with a dial gauge. Run-out should not exceed 0.0035 in. (0.089 mm). Run-out can be corrected for somewhat by loosening the four disc nuts and repositioning the disc. Retighten the nuts in an "X" pattern to 20 ft lbs.

MAINTENANCE

NOTE: Common maintenance procedures are explained in detail in "General Information."

LUBRICATION

Engine

The crankshaft bearings, cylinder(s) and piston(s) are lubricated by the Yamaha "Autolube" oil injection system.

The system does not require maintenance except for a periodic check on oil pump cable adjustment and stroke provided that the Autolube tank is kept full of oil. A level glass is provided for this purpose.

Autolube tank oil level mark (Courtesy Yamaha Int. Corp.)

"Yamalube" oil is recommended by the factory. If this is not available, one of the following types of oil can also be used:

a. Any high-quality two-stroke oil labeled "BIA certified for service TC-W.";

b. Any high-quality SAE 30W two-stroke oil designed for air cooled engines;

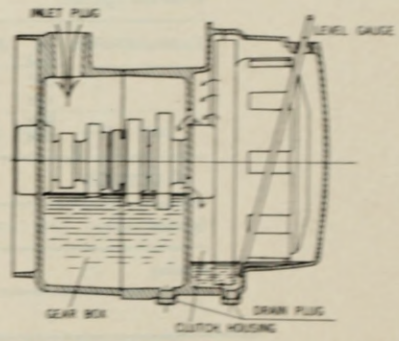
c. A high-quality detergent-type motor oil, SAE 30W, rated "SE." This should be used only if two-stroke oil is not available.

In extremely cold weather (average temperature below 15° F) use a high-quality detergent motor oil rated "SE," with a viscosity of SAE 10W-30. Each time you add oil, check that the oil tank cap breather hole is not clogged, or that the tank breather tube is not clogged or pinched at any point.

NOTE: If the tank ever runs out of oil, or if the feed line is disconnected for any reason, it will be necessary to bleed the system before operating the motorcycle. Refer to the "Lubrication System" chapter for procedures.

Transmission

The transmission and clutch are lubricated by an oil bath. Yamalube 4-cycle oil, SAE 10W–3, or SAE 30W service rating "SE" is recommended for all models.



CHECKING OIL

1. The machine should be on the center stand, preferably on a level surface, when checking the transmission oil level.

2. The engine should be warm.

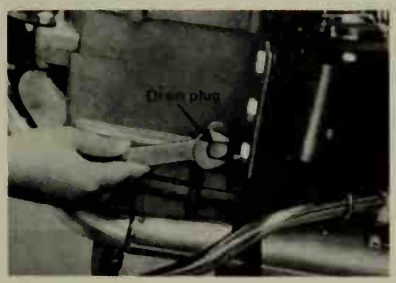
3. If a dipstick is provided, unscrew it and wipe it off. Reinsert, allowing the dipstick cap to rest on top of the threads of its hole. The oil level should be between the maximum and minimum marks on the dipstick. If too low, add oil until the level is correct.

4. On some older models, the dipstick and cap are separate. Remove the inspection cap, and then check the oil level as outlined above. A separate plug may be fitted to add oil. On machines such as the YA6, this plug is accessible after removing the left air cleaner cover. Refer to the illustration. On this type of machine, oil *must not* be added through the level inspection hole because of the difference between transmission and clutch oil levels.

On early models such as the YA6, transmission oil must be added to the crankcases only. If oil is added through the level gauge hole in the clutch cover, an incorrect level reading will be obtained (Courtesy Yamaha Int. Corp.)

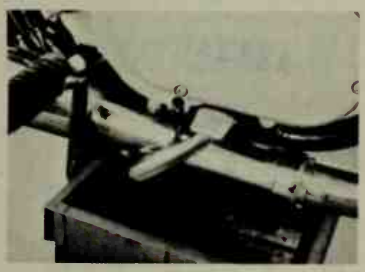
5. If no dipstick is supplied, the oil level is checked by means of a level screw or bolt near the bottom of the clutch cover. When the screw or bolt is removed the oil should just begin to seep out if the level is correct. If necessary, add oil through the filler hole on top of the crankcases or clutch cover until the oil just begins to come out of the level plug hole.

CHANGING OIL



The transmission oil should be changed at least every 2,000 miles after break-in is over.

1. The machine should be on the center stand and parked on a level surface.

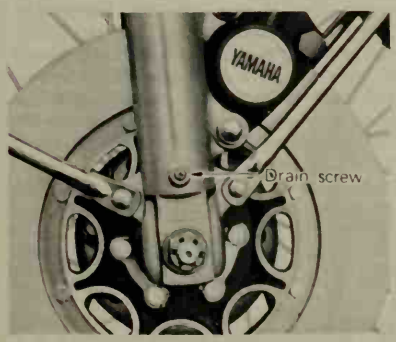


2. Remove the dipstick (or the inlet plug on older models).

3. Remove the drain plug(s) and allow the oil to drain off for several moments. Most late model machines have one drain

plug located at the bottom of the crankcases. Others have the drain plug located at the bottom side of the clutch case. Still others (DS6, R3) have plugs at both of these locations, and both should be removed to ensure that all the old oil is drained.

Removing the transmission drain plug (Courtesy Yamaha Int. Corp.)



On some models, the drain plug is located on the side of the cases (R3) (Courtesy Yamaha Int. Corp.)

4. Fill the transmission with the correct type and quantity of oil. Capacities are given in the chart at the end of this section. They are approximates. After filling, allow a moment for the oil to distribute itself, then check the level with the dipstick or level plug.

NOTE: *The use of oil additives is not recommended, since they may cause clutch slippage.*

Front Forks

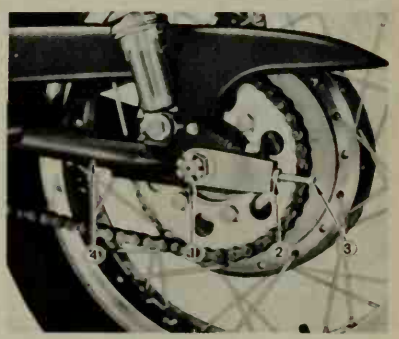
1. Yamaha fork oil is recommended for the front forks.
2. Fork oil should be changed every 2,000 miles.

Front fork drain screw location (RD350 shown) (Courtesy Yamaha Int. Corp.)

3. To drain the fork oil, remove the drain plug at the lower portion of one of the fork sliders. Allow the oil to drain into a suitable container; pump the slider up and down several times. (Sit on the machine after taking it off the center stand, apply the front brake, and push forward). After most of the oil is expelled, turn the forks all the way to the right to completely drain the right fork leg, or to the left for the left fork leg. Check the condition of the drain plug gasket. Replace it if necessary. Refit and tighten the drain plug.
4. Repeat the procedure with the other fork leg.
5. Remove the fork filler bolt from the top of each fork leg. If a large filler bolt is fitted (as on most twins), the handlebar clamps may have to be loosened and the bars pulled back to allow access to the fork bolts. Loosening the triple clamp pinch-bolts may make removal easier.

Removing the fork filler bolt (Courtesy Yamaha Int. Corp.)

6. Add the correct quantity and viscosity of oil to each fork leg. Capacities for each model are given in the "Maintenance Data" chart at the end of this section.
7. Inspect the condition of the fork bolt O-rings, if they are fitted to your model, and replace them if torn or cracked. Fit the bolts and tighten them securely. Tighten the handlebar and pinch-bolts if they were loosened. Allow a moment for the oil to settle in the forks before operation.



Chassis Lubrication

1. The swing arm pivot is fitted with a grease nipple. This item should be lubricated with a good grade of chassis grease every 2,000 miles. Grease should be applied until some of it shows at either end of the swing arm.
2. Some older models are fitted with grease fitting for the brake cams. These should receive no more than one shot of a good quality chassis grease approximately every 2,000 miles.
3. Wheel and steering head bearings are lubricated with bearing grease. This should be accomplished every 4,000 miles. Refer to the "Chassis" section for procedures.

SERVICE CHECKS AND ADJUSTMENTS

Drive Chain

1. The chain should have about ¾ in. (20 mm) of total up-and-down free-play measured in the middle of the lower chain run.
2. *Before* checking or adjusting the chain slack, the following conditions should be met:
   a. The machine should be off the center stand, and with a rider sitting on the seat;
   b. The chain should be clean and well lubricated;
   c. The chain should have been checked for any tight spots by slowly rotating the wheel and checking for variances in the chain tension at different points. If a tight spot exists, the chain should be adjusted to the prescribed free-play at the tight spot. Note, however, that such a condition is indicative of a worn chain and probably sprockets which should be replaced as soon as possible.
3. To adjust the chain, first back off the rear brake adjuster nut if a rod-operated brake is fitted.
4. Remove the axle nut cotter pin and loosen the axle nut several turns. On RD400C models, loosen the caliper bracket shaft nut; loosen the tension bar locknut. Loosen the sprocket hub securing nut. Loosen the locknut on each adjuster bolt.

To adjust the chain, loosen the axle nut (1), loosen the adjuster locknut (2), and turn the adjuster bolts (3) clockwise to move the wheel back (Courtesy Yamaha Int. Corp.)

5. Turn each of the adjuster bolts in by equal amount until chain tension is approximately correct.
6. Check wheel alignment by means of the adjusting marks inscribed on both sides of the swing arm. Be sure that both adjusters are lined up with the same mark on each side. If not, turn one of the adjuster bolts in or out so that alignment is achieved.
7. Tighten the sprocket nut and the axle nut and check the chain tension. Correct if necessary. After adjustment is correct, torque the axle nut to 42–50 ft lbs (under 350cc) or about 100 ft lbs on larger machines. On the RD400C, tighten the caliper bracket shaft nut to 58 ft lbs and the tension bar locknut to 10–16 ft lbs. Fit a new cotter pin. Tighten the adjuster locknuts. Readjust the rear brake.

Clutch

1. The clutch lever should be able to be moved 2–3 mm (1/16–⅛ in.) away from the lever holder before the clutch begins

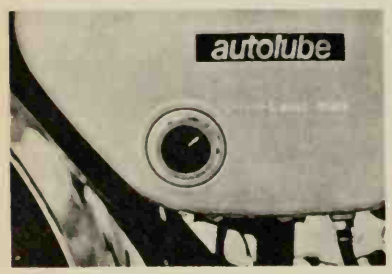
MAINTENANCE



NOTE: *Common maintenance procedures are explained in detail in "General Information."*

LUBRICATION

Engine

The crankshaft bearings, cylinder(s) and piston(s) are lubricated by the Yamaha "Autolube" oil injection system.

The system does not require maintenance except for a periodic check on oil pump cable adjustment and stroke provided that the Autolube tank is kept full of oil. A level glass is provided for this purpose.

Autolube tank oil level mark (Courtesy Yamaha Int. Corp.)

"Yamalube" oil is recommended by the factory. If this is not available, one of the following types of oil can also be used:

a. Any high-quality two-stroke oil labeled "BIA certified for service TC-W.";

b. Any high-quality SAE 30W two-stroke oil designed for air cooled engines;

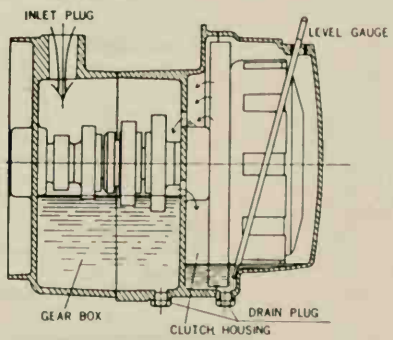
c. A high-quality detergent-type motor oil, SAE 30W, rated "SE." This should be used only if two-stroke oil is not available.

In extremely cold weather (average temperature below 15° F) use a high-quality detergent motor oil rated "SE," with a viscosity of SAE 10W-30. Each time you add oil, check that the oil tank cap breather hole is not clogged, or that the tank breather tube is not clogged or pinched at any point.

NOTE: *If the tank ever runs out of oil, or if the feed line is disconnected for any reason, it will be necessary to bleed the system before operating the motorcycle. Refer to the "Lubrication System" chapter for procedures.*

Transmission

The transmission and clutch are lubricated by an oil bath. Yamalube 4-cycle oil, SAE 10W-3, or SAE 30W service rating "SE" is recommended for all models.



CHECKING OIL

1. The machine should be on the center stand, preferably on a level surface, when checking the transmission oil level.

2. The engine should be warm.

3. If a dipstick is provided, unscrew it and wipe it off. Reinsert, allowing the dipstick cap to rest on top of the threads of its hole. The oil level should be between the maximum and minimum marks on the dipstick. If too low, add oil until the level is correct.

4. On some older models, the dipstick and cap are separate. Remove the inspection cap, and then check the oil level as outlined above. A separate plug may be fitted to add oil. On machines such as the YA6, this plug is accessible after removing the left air cleaner cover. Refer to the illustration. On this type of machine, oil *must not* be added through the level inspection hole because of the difference between transmission and clutch oil levels.

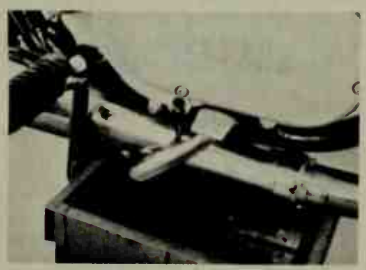
On early models such as the YA6, transmission oil must be added to the crankcases only. If oil is added through the level gauge hole in the clutch cover, an incorrect level reading will be obtained (Courtesy Yamaha Int. Corp.)

5. If no dipstick is supplied, the oil level is checked by means of a level screw or bolt near the bottom of the clutch cover. When the screw or bolt is removed the oil should just begin to seep out if the level is correct. If necessary, add oil through the filler hole on top of the crankcases or clutch cover until the oil just begins to come out of the level plug hole.

CHANGING OIL

The transmission oil should be changed at least every 2,000 miles after break-in is over.

1. The machine should be on the center stand and parked on a level surface.



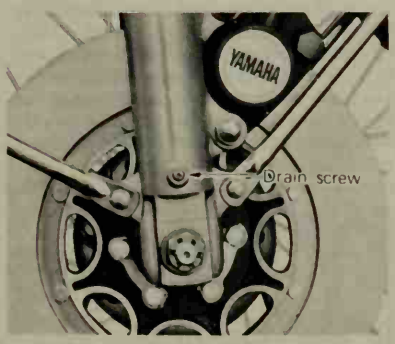
2. Remove the dipstick (or the inlet plug on older models).

3. Remove the drain plug(s) and allow the oil to drain off for several moments. Most late model machines have one drain

plug located at the bottom of the crankcases. Others have the drain plug located at the bottom side of the clutch case. Still others (DS6, R3) have plugs at both of these locations, and both should be removed to ensure that all the old oil is drained.

Removing the transmission drain plug (Courtesy Yamaha Int. Corp.)

On some models, the drain plug is located on the side of the cases (R3) (Courtesy Yamaha Int. Corp.)



4. Fill the transmission with the correct type and quantity of oil. Capacities are given in the chart at the end of this section. They are approximates. After filling, allow a moment for the oil to distribute itself, then check the level with the dipstick or level plug.

NOTE: *The use of oil additives is not recommended, since they may cause clutch slippage.*

Front Forks

1. Yamaha fork oil is recommended for the front forks.

2. Fork oil should be changed every 2,000 miles.

Front fork drain screw location (RD350 shown) (Courtesy Yamaha Int. Corp.)

3. To drain the fork oil, remove the drain plug at the lower portion of one of the fork sliders. Allow the oil to drain into a suitable container; pump the slider up and down several times. (Sit on the machine after taking it off the center stand, apply the front brake, and push forward). After most of the oil is expelled, turn the forks all the way to the right to completely drain the right fork leg, or to the left for the left fork leg. Check the condition of the drain plug gasket. Replace it if necessary. Refit and tighten the drain plug.

4. Repeat the procedure with the other fork leg.

5. Remove the fork filler bolt from the top of each fork leg. If a large filler bolt is fitted (as on most twins), the handlebar clamps may have to be loosened and the bars pulled back to allow access to the fork bolts. Loosening the triple clamp pinch-bolts may make removal easier.

Removing the fork filler bolt (Courtesy Yamaha Int. Corp.)

6. Add the correct quantity and viscosity of oil to each fork leg. Capacities for each model are given in the "Maintenance Data" chart at the end of this section.

7. Inspect the condition of the fork bolt O-rings, if they are fitted to your model, and replace them if torn or cracked. Fit the bolts and tighten them securely. Tighten the handlebar and pinch-bolts if they were loosened. Allow a moment for the oil to settle in the forks before operation.

Chassis Lubrication

1. The swing arm pivot is fitted with a grease nipple. This item should be lubricated with a good grade of chassis grease every 2,000 miles. Grease should be applied until some of it shows at either end of the swing arm.

2. Some older models are fitted with grease fitting for the brake cams. These should receive no more than one shot of a good quality chassis grease approximately every 2,000 miles.

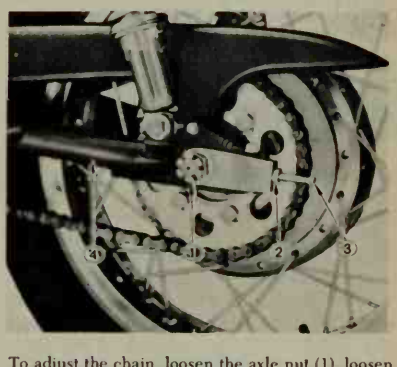
3. Wheel and steering head bearings are lubricated with bearing grease. This should be accomplished every 4,000 miles. Refer to the "Chassis" section for procedures.

SERVICE CHECKS AND ADJUSTMENTS

Drive Chain

1. The chain should have about ¾ in. (20 mm) of total up-and-down free-play measured in the middle of the lower chain run.

2. *Before* checking or adjusting the chain slack, the following conditions should be met:



a. The machine should be off the center stand, and with a rider sitting on the seat;

b. The chain should be clean and well lubricated;

c. The chain should have been checked for any tight spots by slowly rotating the wheel and checking for variances in the chain tension at different points. If a tight spot exists, the chain should be adjusted to the prescribed free-play at the tight spot. Note, however, that such a condition is indicative of a worn chain and probably sprockets which should be replaced as soon as possible.

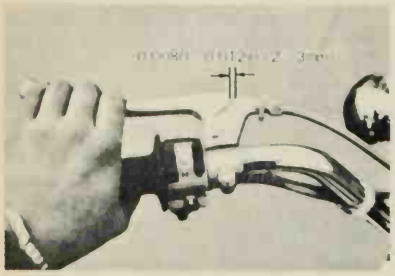
3. To adjust the chain, first back off the rear brake adjuster nut if a rod-operated brake is fitted.

4. Remove the axle nut cotter pin and loosen the axle nut several turns. On RD400C models, loosen the caliper bracket shaft nut; loosen the tension bar locknut. Loosen the sprocket hub securing nut. Loosen the locknut on each adjuster bolt.

To adjust the chain, loosen the axle nut (1), loosen the adjuster locknut (2), and turn the adjuster bolts (3) clockwise to move the wheel back (Courtesy Yamaha Int. Corp.)

5. Turn each of the adjuster bolts in by equal amount until chain tension is approximately correct.

6. Check wheel alignment by means of the adjusting marks inscribed on both sides of the swing arm. Be sure that both adjusters are lined up with the same mark on each side. If not, turn one of the adjuster bolts in or out so that alignment is achieved.



7. Tighten the sprocket nut and the axle nut and check the chain tension. Correct if necessary. After adjustment is correct, torque the axle nut to 42–50 ft lbs (under 350cc) or about 100 ft lbs on larger machines. On the RD400C, tighten the caliper bracket shaft nut to 58 ft lbs and the tension bar locknut to 10–16 ft lbs. Fit a new cotter pin. Tighten the adjuster locknuts. Readjust the rear brake.

Clutch

1. The clutch lever should be able to be moved 2–3 mm (1/16–⅛ in.) away from the lever holder before the clutch begins

to disengage.

2. If your model is equipped with an adjuster and locknut at the clutch lever, use these to effect the proper adjustment. If not, an adjuster is fitted to the clutch

cable where it enters the crankcase cover. Loosen the locknut, and turn the adjuster in or out to increase or decrease lever free-play as needed.

3. If adjusting the cable does not provide satisfactory clutch performance, the pushrod should be adjusted.

On most twins, the pushrod is accessible after removing the cover plate from the left crankcase cover. On the RD60, the alternator cover is removed. On G-series machines, remove the right crankcase cover. On some older models, the pushrod is covered by a rubber plug on the crankcase cover.

Adjusting the clutch pushrod

4. Run down the cable adjuster until a good amount of free-play exists in the cable.

5. Remove the cover or plug to gain access to the pushrod adjuster. Loosen the pushrod adjuster locknut and back it off several turns.

6. Turn the pushrod adjuster screw in until it just touches the clutch pushrod (a slight resistance will be felt). Back off the screw ¼ turn. Holding this adjustment, tighten the locknut.

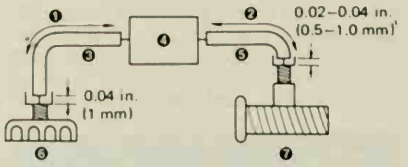
7. Adjust the cable to give the proper lever free-play, and check clutch operation.

Throttle Cables

ALL MODELS EXCEPT RD400

1. Throttle cables should be adjusted *after* the idle speed. This procedure is given in the "Tune-Up" section.

2. The oil pump cable must be adjusted after adjusting the throttle cable(s).



3. A cable adjuster is fitted to the top of the carburetor and another at the twist-grip. One throttle cable runs from the twist-grip to a junction box. There, it is connected to the oil pump cable and one or two (on twins) shorter throttle cables which run to the carburetor(s). Therefore, each cable must be adjusted.

4. After setting the idle speed, use the adjuster on the carburetor cap to give 1 mm (0.04 in.) of cable free-play. This can be measured by gently lifting the cable out of the adjuster. It should come out no

Checking throttle cable free-play by lifting the cable nut of the adjuster until tension is felt

more than the amount shown before the throttle slide begins to rise. On twins, adjust both cables. Loosen the locknut and

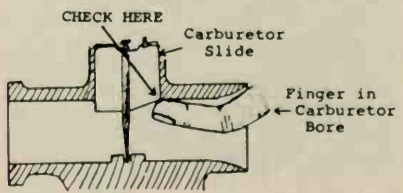
screw the adjuster clockwise (in) to increase the slack and counterclockwise (out) to decrease it. Tighten the locknut.

5. Adjust the long throttle cable with the adjuster at the twist-grip. This cable should be adjusted to give 0.5–1.0 mm (0.02–0.04 in.) of free-play.



6. On twins, the throttle slides must now be synchronized. Remove the air

On twins, the throttle slides must be synchronized as shown (Courtesy Yamaha Int. Corp.)

cleaner. Turn the twist-grip until the throttle slides just begin to move. Both must begin to move at the same time.

Another synchronization method is to insert your fingers into the carburetor bores to ensure that both throttle slides clear the bore at the same time. You will be able to feel when one slide becomes just flush with the uppermost part of the bore. The other slide must be in exactly the same position. See the illustration.

Throttle slide synchronization may be checked by noting when each slide clears the carburetor bore. When one slide is in this position, the other must be also (Courtesy Yamaha Int. Corp.)

If adjustment is necessary to synchro-

nize the throttle slides, raise or lower the adjusters on the carburetor caps as needed. Screwing one adjuster in a small amount while turning the other out is recommended rather than turning only one of the adjusters to synchronize the slides.

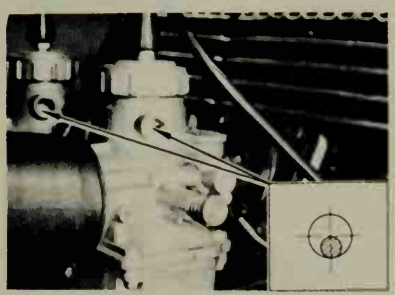
7. On all models, after adjusting the throttle cables, start the engine and turn the forks slowly from lock-to-lock, noting any variation in idle speed. If the revs change, either the cables are adjusted too tightly or are binding somewhere along their routing.

8. Adjust the oil pump cable.

RD400

1. Refer to Steps 1–5 for other models, above.

2. Remove the inspection plugs from the carburetors.



3. Turn the twist-grip fully open. In this position, the punch marks on the throttle slides should align with the lower edge of the inspection holes.

4. If they do not, use the cable adjusters atop each carburetor so that the slides are properly synchronized.

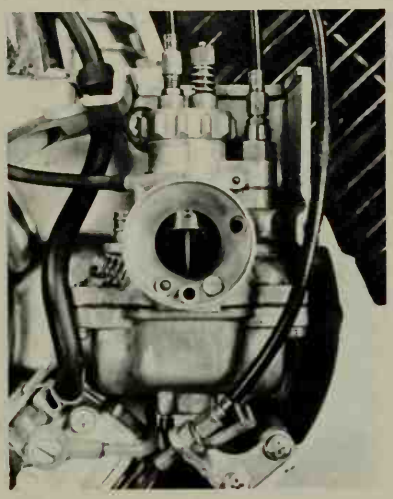
5. Snap the throttle open and shut several times and recheck alignment of the punch marks.

6. Check that proper free-play exists in the cables.

7. Check the oil pump cable adjustment.

Throttle slide punch marks aligned (RD400C) (Courtesy Yamaha Int. Corp.)

Oil Pump Cable

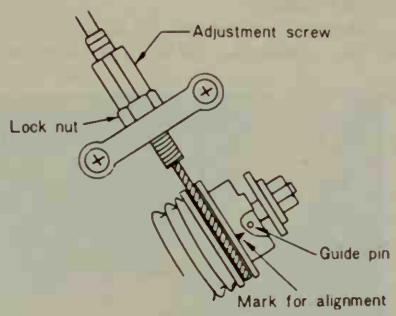


ALL MODELS EXCEPT RD400

1. Set the throttle cable adjustments as previously described.

2. Remove the oil pump cover. On rotary valve models, this will expose the carburetor as well.

3. On rotary valve models, note the punch mark on the throttle slide. Turn the throttle twist-grip until the upper part of the punch mark aligns with the top of the carburetor bore. Holding the throttle in this position, check that the mark on the oil pump pulley is aligned with the oil pump guide pin. If it is not, loosen the locknut, and turn the oil pump cable adjuster in or out until alignment is achieved. Tighten the locknut.



4. On piston-port models, turn the throttle twist-grip until all slack is taken out of the cables, but the throttle slide(s) have not moved. At this point, the raised mark on the oil pump pulley should align with the oil pump guide pin. If it does not, loosen the locknut on the oil pump cable adjuster located in the sidecover and turn the adjuster in or out until adjustment is achieved.

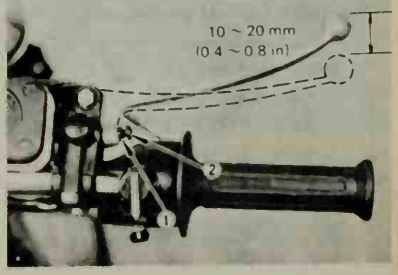
5. Periodically, the oil pump minimum stroke should be checked. Refer to the "Lubrication System" section.

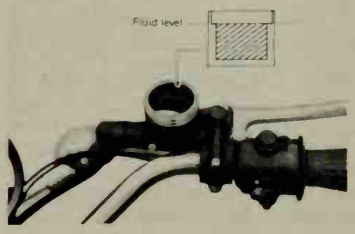
RD400

1. Set the throttle cable adjustments as previously described. Remove the oil pump cover.



2. With the throttle held fully open, the plunger pin on the oil pump should align with the mark on the pump pulley.

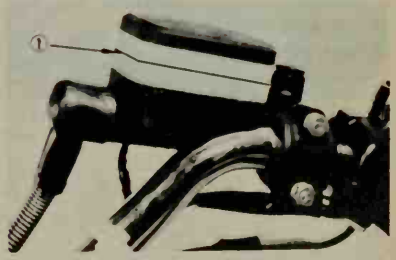
3. If it does not, adjust with the oil pump cable adjuster threaded into the crankcase cover until the plunger pin and pulley mark are aligned.



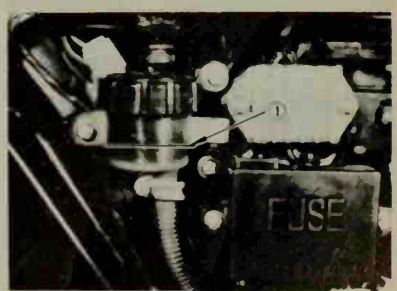
Brakes

FRONT DISC

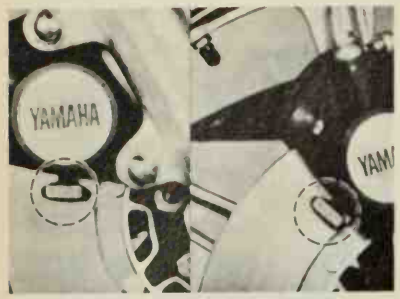
1. The brake lever is fitted with an adjusting screw. The lever should have about 20 mm (0.8 in.) of free-play, measured as shown in the illustration. To adjust, loosen the locknut and turn the adjusting screw in or out. Then tighten the locknut.



Front disc brake lever adjustment (Courtesy Yamaha Int. Corp.)



Master cylinder fluid level (Courtesy Yamaha Int. Corp.)



2. Maintain the brake fluid level in the master cylinder at the level line inscribed on the master cylinder. Although the fluid level may drop slightly as the pads wear, this drop should not be significant.

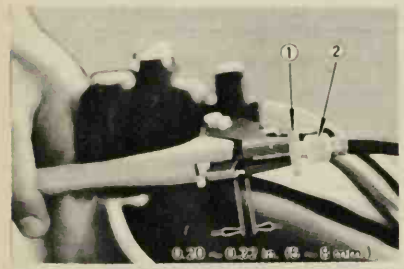
Rear disc brake lower fluid level mark (1) (RD400C) (Courtesy Yamaha Int. Corp.)

Front and rear brake pad wear indicators (Courtesy Yamaha Int. Corp.)



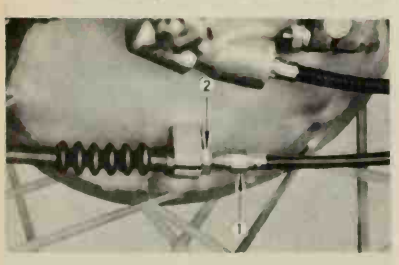
3. Pads should be checked periodically for wear. Replace them when worn to or near the red limit line or when the wear indicator shows the need for replacement. Refer to the "Chassis" section for pad replacement procedures.

4. The brake hoses should be checked for seepage or abrasion damage often, and should be replaced if they show wear or leakage of any kind. Make sure that the lines touch the frame or forks at the mounting points only.

5. Every 8,000 miles or 1 year, the brake system should be flushed and refilled with fresh fluid. Refer to the "Chassis" section for procedures.

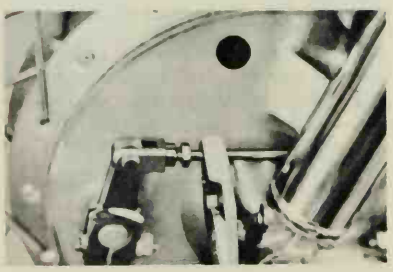
FRONT DRUM

1. Use the cable adjuster on the brake plate to allow about ¼ in. (6 mm) of brake handlebar lever free-play before the shoes contact the drum. This free-play is to be measured between the lever and the lever holder.



Front drum brake lever adjustment is measured between the lever and the holder (Courtesy Yamaha Int. Corp.)

2. This free-play can be maintained as the shoes wear by using the adjuster at the handlebar lever.



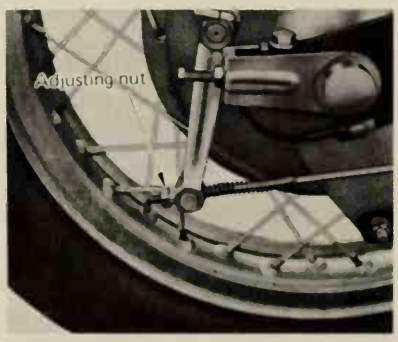
3. The linkage of twin-leading shoe front brakes ordinarily does not need adjustment. If the backing plate has been disassembled, or adjustment is felt to be necessary because of weak brakes, proceed as follows:

a. Loosen the locknut on the rod connecting the two brake cam levers on the brake plate;

b. Use a vise-grip pliers (protecting the rod with a rag) to turn the rod so that the distance between the ends of the two levers *decreases;*

Front brake adjuster on the brake plate (Courtesy Yamaha Int. Corp.)

Adjusting the twin-leading shoe brake rod (Courtesy Yamaha Int. Corp.)



c. Apply the brake. The lever which is connected directly to the cable will raise its brake shoe to contact the drum;

d. Turn the connecting rod so that the distance between the two levers *increases*, and continue until it is no longer possible to turn the rod. The second lever will have raised its shoe against the brake drum at this point and the linkage is adjusted. Tighten the rod locknut.

e. Adjust the brake cable.

REAR DRUM

Use the adjusting nut on the end of the cable or rod so that the brake pedal has 25 mm (1 in.) of free-play before the linings contact the drum. On models with rod-operated brakes, make the adjustment with a rider on the machine.

Rear brake adjusting nut (Courtesy Yamaha Int. Corp.)

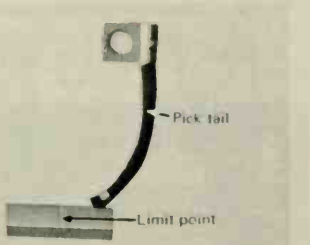
NOTE: *If the angle between the brake cable or rod and the lever on the brake plate exceeds 90° when the brake is applied, the lining thickness should be checked. On some models, this can be done by removing the brake plate inspection cap.*

REAR DISC

The RD400C is fitted with a rear disc. All points noted above for front disc brakes are applicable. A wear indicator is fitted to check pad condition.

To adjust the brake pedal, loosen the brake rod locknut and turn the adjuster in or out so that the brake has 5–10 mm (0.2–0.4 in.) of free pedal movement. Tighten the locknut.

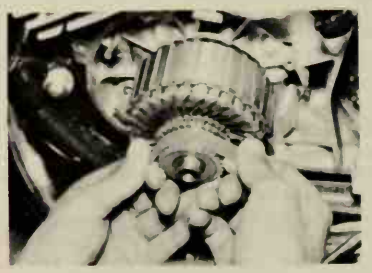
BRAKE LIGHT SWITCH



The switches should be checked for operation after the brake is adjusted. The rear brake light switch is mounted in a slotted bracket and secured by locknuts. Moving the light switch up on the bracket allows the brake light to turn on sooner. Moving it down allows it to come on later. Generally, the brake light should come on just before the linings contact the drum.

Steering Stem Bearings

The steering stem bearings should be checked periodically and adjusted if necessary. Refer to the "Chassis" section.



Generator

1. Begin inspection of the carbon brushes on machines with (DC) generators after 4,000 miles. Brushes will usually have a wear limit line marked on them. Refer to the "Electrical Systems" section for wear limits.

Generator brush wear limit line (Courtesy Yamaha Int. Corp.)

2. Clean off the generator commutator with a gasoline-soaked rag. The commutator surface can be polished with #400–600 sandpaper or fine emery cloth. After polishing, clean the commutator thoroughly. Check the mica undercut.

Periodic Maintenance

Mileage intervals indicate maintenance under average riding conditions. Services should be performed more often under adverse conditions or hard usage.

Daily (before each ride)
- Check lighting equipment and horn operation
- Check operation and adjustment of the brakes
- Tire condition
- Chain tension
- Cable adjustments
- Autolube tank oil level

Weekly
- Transmission oil level
- Tire pressure (cold)
- Spoke tension
- Battery electrolyte level
- Chain condition
- Critical nuts and bolts

Monthly
- Trickle charge stored battery

Every 200 miles
- Lubricate chain

Every 2000 miles
- Change transmission oil
- Remove, clean, and lubricate chain
- Lubricate grease fittings
- Lubricate control and instrument cables
- Decarbonize engine
- Check oil pump adjustment
- Clean fuel petcock
- Check brake fluid level (disc brake)
- Grease speedometer drive mechanism
- Change fork oil

Every 3000 miles
- Clean or replace air cleaner

Every 4000 miles
- Disassemble and clean carburetors
- Check generator brushes
- Check brake linings
- Pack wheel and steering head bearings

Every 8000 miles
- Flush hydraulic disc brake system

or replacing the air cleaner, and cleaning the carburetor(s).

2. The carburetor(s) should be removed, disassembled, and cleaned every 4,000 miles. The procedures are outlined in the "Fuel Systems" section.

Removing the petcock sediment bowl

3. The petcock should be serviced every 2,000 miles. Shut the fuel off, then unscrew and remove the petcock sediment bowl. Take out the fuel filter. Clean the parts in a solvent and reinstall. Check for leaks.

4. The air cleaner should be serviced or replaced every 2–3,000 miles, depending on conditions. If the air cleaner is the paper type, it should be kept free of water, solvents, etc.

The paper filters can be cleaned, after a fashion, by tapping off heavy dirt deposits, or brushing off the outside, and blowing compressed air through the inside of the filter element. These techniques, however, are limited in usefulness, and it is really preferable to replace the element every 5,000 miles or so (once again, depending on conditions).

Where filters are a tight fit in their housings, some liquid detergent or a bit of oil can be applied to the end plates to facilitate installation.

If a foam-type air cleaner is used, wash it in gasoline to remove dirt, and squeeze until it is dry. Immerse the filter in light motor oil (20 or 30 W) and squeeze off the excess oil. Then install on the machine.

TUNE-UP

NOTE: *Common tune-up procedures are explained in detail in "General Information." A dial gauge and "Points Checker" (ohmmeter) are necessary for ignition timing. On battery-ignition machines, a test or continuity light can be used in place of the Points Checker.*

CONTACT BREAKER POINTS

Location

1. On single-cylinder machines with magneto ignition, breaker points are located beneath magneto flywheel (rotor) on the left-side of the engine. Remove the left-side engine cover to gain access to the points. Cutouts are provided in the rotor to allow the points to be cleaned and gapped.

2. On single-cylinder machines with electric starters, the points are located beneath a cover plate on the left-side engine cover.

3. Twin-cylinder machines have two sets of points which run off the crankshaft. Except for YDS and DS6 models, the points are located on the left-side of the engine and are accessible for cleaning and gapping or replacing after removing the point cover.

On YDS and DS6 models, the points are located on the right-side of the engine.

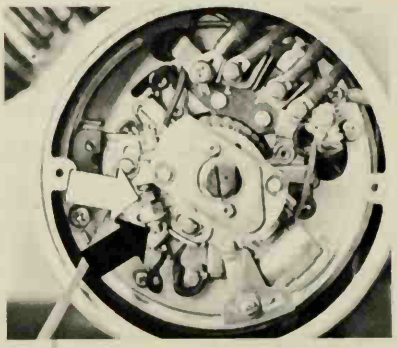
Gapping

Points should be filed (if necessary) or cleaned before gapping.

SINGLES—MAGNETO IGNITION

1. After removing the magneto cover, turn the magneto rotor so that the breaker points are visible through one of the cutouts.

2. Position the rotor so that the breaker points are fully open, then check the gap with a feeler gauge. Refer to the "Tune-Up Specifications" chart at the end of this section for the proper point gap for your model. The feeler gauge should be a light slip fit between the open points.



3. If the gap is not within specification, adjust by loosening the locknut and screwing the fixed point in or out on its bracket to increase or decrease the gap until it is correct. Retighten the locknut and recheck the gap.

SINGLES—BATTERY IGNITION

1. Remove the points cover and turn the engine over until the points are fully open.

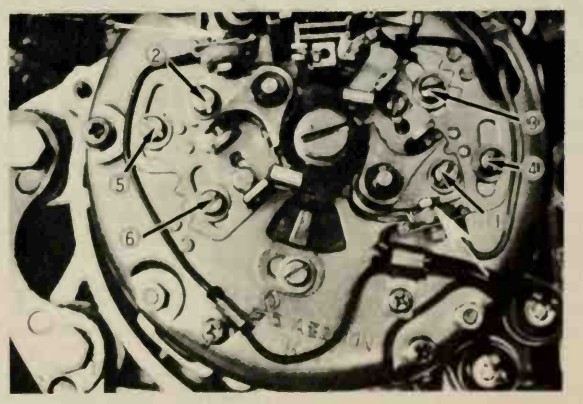
2. With the proper feeler gauge, check the point gap. Be sure to use the correct gap for your machine as given in the "Tune-Up Specifications" chart at the end of this section.

3. The feeler gauge should be a light slip fit between the points.

On early models, the point gap is adjusted by loosening the locknut and turning the adjuster screw (black arrow) so that the fixed point (white arrow) is the correct distance from the moveable point

4. If the gap is not within specification, loosen the locknut, and screw the fixed point in or out on its bracket to increase or decrease the gap as needed. Retighten the locknut and recheck the gap.

TWINS



Two sets of points are used and they are adjusted independently. Be sure that both sets are set to exactly the same gap.

1. After removing the breaker point cover plate, rotate the engine so that either set of points is fully open.

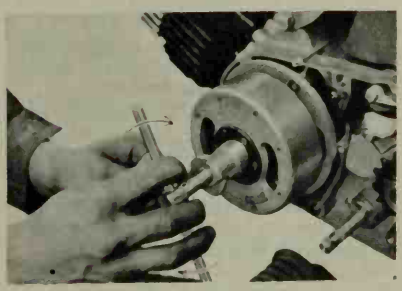
2. Check the gap with the proper feeler gauge. Refer to the "Tune-Up Specifications" chart at the end of this section for the proper point gap for your machine.

3. If the gap is not within specification, it must be adjusted. On older models (those with a fixed point secured by a locknut), loosen the locknut and screw the fixed point in or out on its bracket so that the gap is correct. Secure the locknut.

On all newer models, the fixed point is a part of a plate and is secured with a screw; refer to the accompanying illustration. Loosen the fixed point securing screw and with a thin screwdriver applied to the pry slot provided, move the fixed point towards or away from the

On recent twins, the point gap is adjusted after loosening the screws (1 and 2). Screws 3, 4, 5, and 6 are used to adjust the ignition timing. The white arrows indicate the points' primary wire terminals (Courtesy Yamaha Int. Corp.)

movable point until the gap is correct.



4. Tighten the fixed point securing screw and recheck the gap.

5. Turn the engine over until the other set of points is open, and repeat the procedure.

Replacement

MAGNETO IGNITION

Two special tools are needed to replace the points on magneto-ignition machines. A holder is used to hold the magneto rotor steady while the nut is removed, and a special puller, threaded

Removing the magneto rotor (Courtesy Yamaha Int. Corp.)

into the center of the rotor, is used to pull it off its tapered shaft.

CAUTION: *The rotor puller is essential for this job. It is not wise to attempt to remove the rotor in any other way.*

1. Remove the left-side engine cover, after loosening the pinch-bolt and pulling the gearshift lever off its shaft. The use of an impact driver to remove and install phillips head case screws is recommended.

2. Holding the magneto rotor with the special tool, or a suitable substitute, loosen and remove the rotor nut.

NOTE: *Alternately, engage the transmission and apply the rear brake to hold the rotor if a shop holder is not available.*

3. Thread the rotor puller into the rotor. The puller bolt should be backed off enough so that the puller outer has a good number of threads in the rotor.

NOTE: *The puller outer has a left-hand thread. Thread it into the rotor in a counterclockwise direction.*

4. Tighten the puller bolt against the end of the crankshaft to remove the rotor. The rotor should come off the taper. If it is stuck, tighten the puller bolt as much as possible and give it a sharp rap with a hammer. This should free the rotor. Note the key fitted to the crankshaft.

CAUTION: *Never use heat in an attempt to remove the rotor, since this may affect its magnetic properties. Handle the rotor with care: avoid dropping or striking it, as this, too, will affects its magnetism.*

5. Disconnect the primary wire from the breaker point terminal, then remove the securing screw. Remove the old points set.

6. Clean the contact surfaces of the new set of points to remove any protective coating present. Install the points and reconnect the primary wire.

7. Grease or oil the crankshaft taper slightly before fitting the rotor to make removal easier next time. Line up the slot in the rotor with the key in the crankshaft. Push the rotor into place. If the puller is still fitted back off the puller bolt, and strike the puller bolt once or twice to ensure that the rotor is firmly seated, but do not strike the rotor itself. Refit the rotor nut and tighten it securely. Reset the point gap and check the ignition timing.

BATTERY AND COIL IGNITION

1. Remove the breaker point cover.

2. Disconnect the primary wire at the breaker points terminal, and remove the securing screw. Remove the old points. On twins, install one set of new points before removing the other old set.

3. Before installing new points, be sure to clean off the breaker point surfaces with a solvent to remove any protective coating.

4. Install the new points, tightening the securing screw lightly. Reconnect the terminal primary wire. Be sure that the small nut is firmly secured.

5. Adjust the point gap and recheck the ignition timing.

Lubrication

1. Whenever the point gap is checked or points replaced, it is necessary to lubricate the cam follower fiber heel and the pivot point of the contact breaker. This minimizes wear and ensures that the timing will remain accurate for a longer period. A worn heel will retard the timing.

2. A small dab of grease (high melting point, if possible) or oil should be applied to the lubricator felt so that the lubricator can distribute it onto the breaker cam. A drop of engine oil should be applied to the pivot point.

3. In both cases it is imperative that care be taken to keep the lubricant away from the points.

4. The lubricating felt should be adjusted so that it just contacts the breaker cam.

5. If the felt is missing, or the model not equipped with it, the grease can be sparingly applied to the cam itself.

IGNITION TIMING

NOTE: *Points must be cleaned and gapped before checking the timing. Dirty points will cause inaccurate readings.*

Magneto Ignition

The timing on magneto ignition models is adjusted by changing the point gap. A dial indicator and a points checker are necessary for ignition timing.

1. Clean and gap the points.

2. Remove the spark plug and fit the dial gauge in its place.

3. Slowly rotate the engine until the gauge indicates its highest reading and begins to reverse. The highest reading is top dead center. Turn the engine a few degrees in either direction to recheck your finding. Then zero the gauge.

4. Attach the negative (black) lead of the ohmmeter or Point Checker to the engine case (ground), and the positive (red) lead to the breaker point primary wire.

5. Turn the engine "backward" (rotate the rotor clockwise) to a position about 3–4 mm BTDC as indicated by the dial gauge. Since most models fire about 2 mm BTDC, the points will be closed at this point. (Zero resistance on the meter).

6. Slowly turn the engine in the normal direction of rotation until the dial gauge indicates that the piston is at the firing point. This point is given for each model in the "Tune-Up Specifications" chart at the end of this section.

7. When the piston reaches this point, the points should open (as indicated by the reaction of the checker (if the ignition is correctly timed. If the points open before the correct position, the timing is too advanced. If they open when the piston is past it, the timing is retarded.

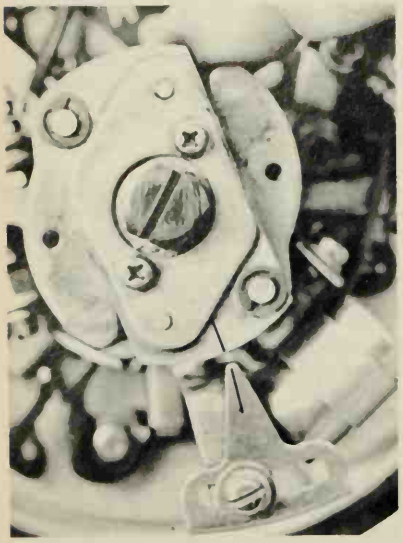
8. If adjustment is necessary, increase or decrease the point gap until the timing is right on. It should be possible to change the gap to correct the timing while still staying within the limits outlined under "Gapping."

9. If the timing was advanced, loosen the fixed point locknut and turn the fixed point to *decrease* the gap. If the timing was retarded, turn the point to *increase* the gap.

10. Repeat the procedure until the points open at the instant the piston reaches the correct distance BTDC. Timing should be within 0.1 mm of the given value. After adjustment, recheck the point gap in the fully open position. As noted above, it should still be within the proper specification. If not, the points should be replaced.

Battery Ignition

On battery ignition machines, a dial gauge is used to find piston position, while the moment of points opening can be determined either with the Point Checker or with a test or continuity light.



On twins, the timing is adjusted for each cylinder independently. Be sure that both sets of points are gapped to the same value, and that the ignition timing is the same for both when you are through.

1. Remove the points cover and clean and gap the breaker points.

2. If a timing advance mechanism is fitted, wedge the counterweights in the OPEN (fully advanced) position.

3. Remove the spark plug(s) and fit the dial gauge. On twins, either cylinder may be timed first.

4. Position the piston at top dead center by turning the engine over by hand until the dial gauge indicates the highest reading and then begins to reverse. The highest reading is top dead center. Turn the crankshaft a few degrees in either direction to check your finding,

On models so equipped, the timing advance weights should be propped open (full advance) when setting the timing

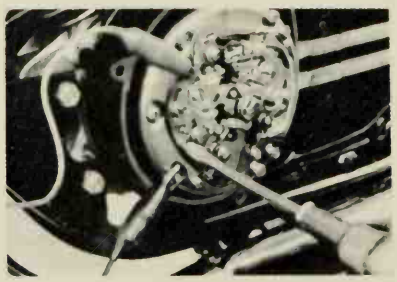
then position the piston at TDC and zero the gauge.

5. Refer to the "Tune-Up Specifications" chart at the end of this section for the proper timing for your machine. Ordinarily, the firing point will be 2 mm or more BTDC.

6. Hook up the test light or Point Checker: one lead to ground on the engine or frame, the other to the primary wire terminal of the points. On twins, the "LH" point set (orange wire) fires the left cylinder, and the "RH" (gray wire) the right cylinder.

7. Turn the crankshaft opposite the normal direction of rotation to about 3–4 mm BTDC. The points should be closed at this position.

8. Slowly rotate the engine in the normal direction of rotation. When the dial indicator shows that the piston is at the proper distance BTDC, the points should open.



9. If the points open before the piston reaches this distance, the timing is too advanced; if they open after it passes the timing distance, the timing is retarded.

10. To adjust the timing, loosen the two timing screws which hold the point mounting plate to the generator housing just enough to allow the points to be moved. Move the points in the direction of crankshaft rotation to correct advanced timing; move them opposite the direction of crankshaft rotation to correct retarded timing.

11. After adjustment, recheck the timing. The points should open at the precise instant which the dial gauge indicates that the piston is correctly positioned. Accuracy must be within 0.1 mm of the given specification.

NOTE: *Tightening the timing screws may change the timing slightly. So check your setting after they are secured.*

12. On twin-cylinder machines, repeat this procedure for the other set of points.

Adjusting the ignition timing: a screwdriver is used to move the points plate as shown (Courtesy Yamaha Int. Corp.)

The timing of the two cylinders must be as nearly identical as possible. They must be at least within 0.05–0.10 mm of each other.

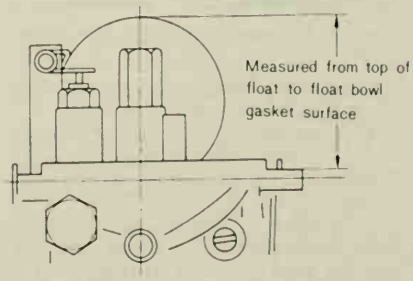
NOTE: *Although not recommended except for emergency situations, the timing marks on the breaker assembly and generator housing can be used as a rough approximation of piston position in the event that a dial gauge is not available. When these marks are aligned (see illustration), the piston is at the firing point and the breaker points should just begin to open. This can be verified with a test light as above or by trapping a very thin piece of paper or cellophane between the points. Tug gently on the paper while slowly rotating the engine. As the timing marks align, the paper should come free. If the points open before the marks align, the timing is too advanced; if they open after the moving mark passes the stationary mark, the timing is retarded. Adjust the points as described above to correct.*

Ignition timing marks can be used to approximate ignition timing

Note that this procedure is not as accurate as that using a dial indicator.

CARBURETOR

Three adjustments to be made to the carburetor are float height, idle mixture, and idle speed. For the first of these, the carburetor(s) must be removed from the machine.

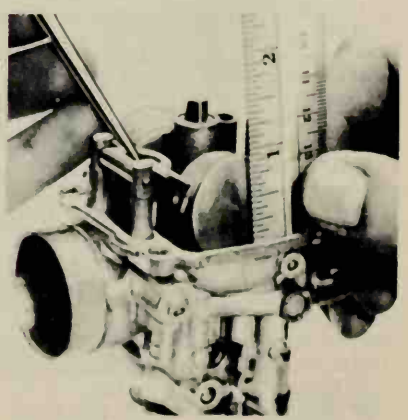


Adjusting Float Height

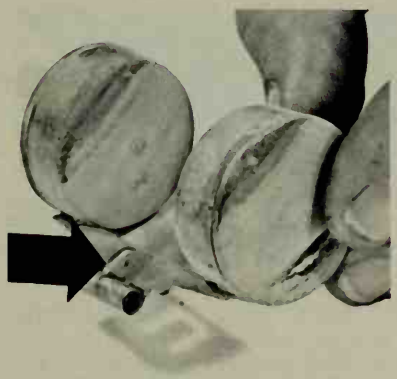
1. Remove the carburetor(s) as outlined in the "Fuel Systems" section.

2. Turn the carburetor upside down, and remove the four float bowl screws carefully lifting off the float bowl.

3. Remove the float bowl gasket.



4. Float height can be measured with a steel rule or a vernier caliper. Float height is defined as the distance from the float bowl gasket surface to the top of the float, when the tang of the float arm is just touching the float needle.



The float level is measured from the top of the float to the gasket surface. The gasket itself must be removed before checking (Courtesy Yamaha Int. Corp.)

NOTE: *Lower the float down until the tang just contacts the float needle. Hold the float in this position, then measure the float height.*

5. Compare the value obtained with the correct specification for your machine given at the end of this section. If the float height is too high or low, pull out the pin which holds the float in place, and bend the tang very slightly to correct the adjustment.

Checking float height

To adjust the float height, bend only the small tang indicated

NOTE: *If float height is too high, bend the tang away from the carburetor body. If too low, bend it toward the carburetor body.*

6. Refit the float and recheck the adjustment.

CAUTION: *Bend only the float tang to make an adjustment. Do not bend the float arms. The floats must be level. If the floats show different heights, the float assembly should be replaced. This indicates that the float assembly has been mishandled.*

7. Float height will not be correct if the needle is worn or if there is foreign matter on the needle seat.

Idle Speed and Mixture

NOTE: *These must be adjusted when the engine is at operating temperature.*

1. On all rotary valve, and the smaller piston-port models, the idle speed (or throttle stop) screw is located on the carburetor top. On other models it is located on one side of the carburetor body.

2. On some rotary valve models, the pilot air screw is located in the carburetor mouth, and is accessible after removing the carb cover plate (see the illustration). On all other models it is located on one side of the carburetor body.

3. The throttle cable(s) should be adjusted after making the idle speed and mixture adjustments. After adjusting the throttle cables, adjust the oil pump cable. Both of these operations are covered in the "Maintenance" section.

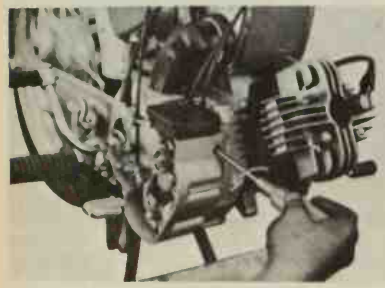
10. On generator-equipped motorcycles, disconnect the wiring harness terminals on the generator.

NOTE: *On some early models, the wiring harness must be disconnected in the battery compartment because the generator terminals are soldered.*



11. Remove the drive chain masterlink spring clip with pliers, remove the cover plate and the masterlink. Disengage the chain from the countershaft sprocket. Install the masterlink on one end of the chain to avoid loss.

12. Remove the carburetor cover. Use an impact driver to loosen the cover screws.

13. Remove the small rubber plug at the side of the carburetor/oil pump compartment. Insert a screwdriver through the hole and loosen the carburetor clamp. Shut off the fuel petcock. Disconnect the carburetor overflow line. Disconnect the fuel feed line at the carburetor. Pull the carb off the mounting spigot and tie it safely out of the way.

14. Remove the screws which secure the oil pump cable adjuster holder, and disconnect the cable from the oil pump.

15. If the clutch cable adjuster is threaded into the crankcase itself, remove the clutch release lever cover (if necessary), disconnect the cable from the lever, and unscrew the cable adjuster from the crankcase.

16. Disconnect the oil pump feed line

at the Autolube tank and plug the tank to prevent oil loss.

17. Remove the air cleaner and disconnect the air cleaner housing from the hose.

18. Disconnect the neutral indicator wire, if accessible; if not (as on G-series machines) proceed to the next step.

19. Remove the upper engine mounting bolts. Loosen the footpeg bolts. Tilt the engine forward until the neutral indicator switch on top of the crankcase is accessible. Disconnect the wire.

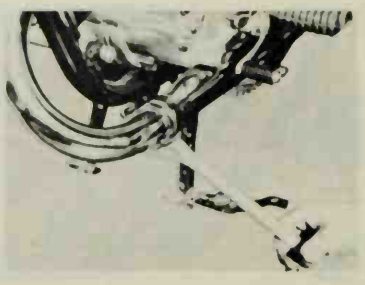
20. Remove the footpegs and take the engine out of the frame.

TWINS

1. Warm the engine up and drain the transmission oil. Replace the drain plug(s) hand-tight. Remove the spark plugs.



2. Shut off the fuel petcock and disconnect the fuel lines at the carburetors.

3. Remove the exhaust pipes. On late models, the headers are unbolted from

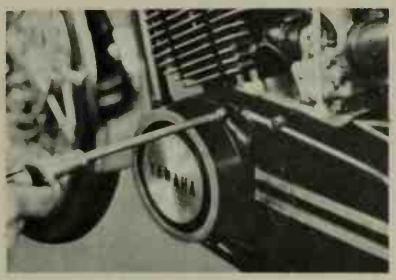
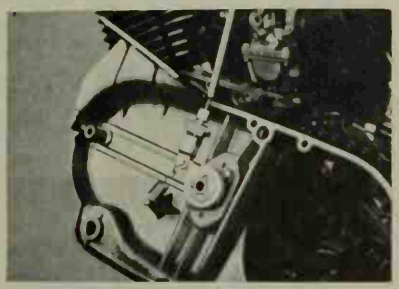
4. Remove the footpegs and the gearshift lever, pulling it carefully off the splined shaft after the pinch-bolt is removed. Remove the shift lever dust seal if fitted.



Removing the oil pump cover (Courtesy Yamaha Int. Corp.)

5. Remove the oil pump cover. Remove the alternator or generator cover and the countershaft sprocket cover. On some machines this side cover is one piece; on others, the sprocket and generator have separate covers.



6. Disconnect the clutch cable at the clutch release lever at the engine and detach the cable from the side cover.

7. Disconnect the alternator or generator wires at the connectors. Disconnect the neutral indicator switch as well.

8. Remove the alternator/generator stator mounting screws and remove the stator assembly.

NOTE: *If the countershaft sprocket will have to be removed after the engine is out of the frame, loosen the sprocket nut or bolts before disconnecting the drive chain. Applying the rear brake hard should stop the sprocket from turning so the nut or*

bolts can be removed. Use a chisel to bend down the tab on the nut lockwasher if fitted.

9. Disconnect the drive chain. On older models this can be done by removing the spring clip with a pair of pliers, taking off the masterlink plate and removing the masterlink. On newer machines (RD-series), the masterlink is pressed on and the chain must be "broken" at the masterlink with the special tool. This tool, or a substitute, must also be used to press the link together for installation. If the special tool is not available and the chain will not come apart, move the rear wheel forward on the adjusters, apply the rear brake hard, bend down the tab on the sprocket lockwasher with a chisel, remove the countershaft sprocket nut, and remove the countershaft sprocket from the shaft.

10. Remove the oil feed line from the tank, plugging the outlet to prevent oil loss. Disconnect the oil pump cable from the pump, then lift up the rubber cover, loosen the locknut, and unscrew the pump cable adjuster from the engine. Some models have the oil pump cable adjuster fitted onto a bracket inside the oil pump compartment. In this case, remove the adjuster bracket screws and arrange the cable out of the way.

11. Loosen the carburetor cap ring nuts and pull the throttle slide assemblies out of the carburetors. Tie the assemblies out of the way so that they will not be damaged during the engine removal procedure.

12. Loosen the carburetor air cleaner clamp screws. On the HS1/B, YAS1/C, AS2 and early YDS models, remove the air cleaners.

13. Loosen the carburetor manifold clamp screws; remove the carburetors from their manifolds together. On most models the carburetors will be connected by a balance tube and starter linkage. Put the carburetors in a safe place after draining off the gasoline in the float bowls.

14. Disconnect the tachometer cable at the engine.

15. On 250, 305, 350 and 400cc models:

a. Remove the engine mounting bolts;

b. On the DS7, R5, and RD-series, remove the upper right rear engine mounting plate;

c. Straddle the machine, grasping the engine by the cooling fins on one side and the kick-starter lever on the other. Pull the engine back slightly, then remove it from the right-side of the frame.

16. On other models:

a. Support the engine with a crate or by having an assistant hold it;

b. Remove the engine mounting bolts, and lower the engine from the frame.

17. On the 100 cc YL1 models:

a. Loosen the upper downtube bolt;

b. Remove the front mounting bolts, and swing the downtube out of the way;

c. Support the front of the engine; remove the upper rear mounting bolt and lower the engine down onto a crate or scisssors jack;

d. Remove the rear mounting bolt and remove the engine from the frame.

Engine Installation

ALL MODELS

1. Installation is basically the reverse of the removal procedure, but the following points should be noted:

a. Engine mounting bolts should be properly torqued. Refer to the chart at the end of this section;

b. On magneto-ignition machines, apply a bit of grease to the crankshaft taper before refitting the magneto rotor. This will make removal easier next time;

c. On all machines, do not forget to install the crankshaft woodruff key for the rotor/armature;

d. Coat the threads of engine case screws with anti-seize compound or a general purpose lubricant to prevent them from seizing in the engine cases. Install them with an impact driver;

e. Replace any worn or damaged exhaust pipe ring nut gaskets;

f. Make sure that all fuel and oil lines are properly seated and secured with circlips;

g. After refilling the transmission and bleeding the oil pump, check all points of adjustment: cables, chain rear brake, ignition timing, carburetor synchronization, oil pump stroke, pump cable adjustment, etc. Install the drive chain masterlink spring clip with the closed end facing the direction of rotation.

TOP END

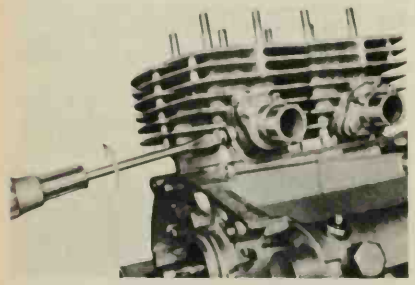
Cylinder Head, Cylinder and Piston

REMOVAL

1. Clean the engine thoroughly to remove any dirt or deposits. The area around the cylinder base is especially important.

2. Remove the spark plug.

3. Disconnect the exhaust pipe from the cylinder. Refer to "Engine Removal" for details.



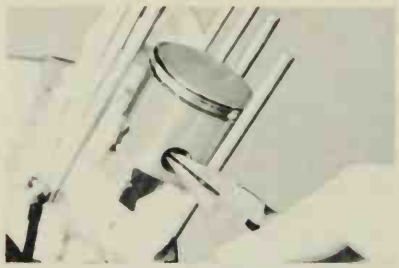
4. On piston-port motorcycles, remove the carburetor from the cylinder.

5. Loosen the four cylinder head nuts ¼ turn at a time in an "X" pattern until they are loose, then remove them and their washers from the studs.

6. Remove the cylinder head and the aluminum cylinder head gasket as well.

NOTE: *The cylinder head may become stuck to the cylinder due to carbon build-up. In this case, tap around the lower edge of head with a plastic mallet until the head is free. Do not strike the cooling fins.*

7. On piston-port models, disconnect the oil feed banjo at the cylinder. Wrap a piece of plastic around the banjo, bolt, and washers. Secure it with a rubber band to prevent the entry of dirt.



Disconnecting the oil line banjo bolts at the cylinders (Courtesy Yamaha Int. Corp.)

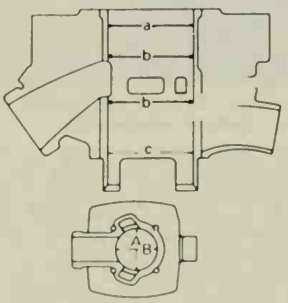
8. Place the piston at top dead center and lift the cylinder off the crankcases until there is enough room to stuff a clean rag between the cylinder and the cases. This will serve to catch any pieces of broken piston ring or dirt which may drop into the cases when the cylinder is removed. Pull the cylinder straight up, catching the piston with one hand when the cylinder is free so that the piston won't hit the studs.

NOTE: *If the cylinder is stuck, it may be freed by tapping around the fins with a plastic mallet.*

9. Remove and discard the cylinder base gasket.

10. Remove the piston wrist pin snap-rings with a needlenose pliers. The rag should remain in place while doing this to prevent one of the snap-rings from falling into the crankcase. Grasp the piston with one hand and push out the wrist pin with a suitable drift. If the pin will not come out, the piston crown may be heated, evenly and gently, with a propane torch. If the pin still resists, it is advisable to use the shop wrist pin removal tool. This consists of a steel band or bands which fit around the piston while the attached screw device is used to push out the pin.

Removing the piston wrist pin snap-rings (Courtesy Yamaha Int. Corp.)



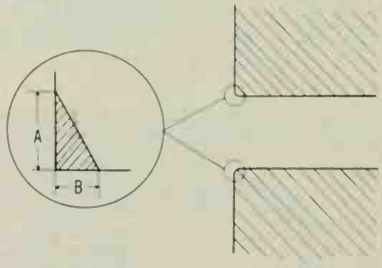
11. When the wrist pin is about ¾ in. out of the piston, grasp the exposed end with a needlenose pliers, and pull it out until it is clear of the connecting rod. Remove the piston from the engine.

CAUTION: *Never strike the wrist pin or attempt to use brute force to drive it out. The connecting rod may be bent in the attempt.*

Cylinder and Piston

INSPECTION AND SERVICE

1. To check for wear of the bore, use an inside micrometer and take bore diameter measurements at the following points, holding the instrument in line with the intake and exhaust ports: just below the top edge of the cylinder; just above the exhaust port; just below the lower edge of the exhaust port; just above the top edge of the cylinder spigot. Record the diameters. Then turn the micrometer 90° and take another set of readings at the same points.



Measure the diameter of the cylinder bore at the four places shown and in directions "A" and "B" (Courtesy Yamaha Int. Corp.)

2. If the difference between the highest and lowest of these eight measurements exceeds 0.05 mm (0.0019 in.), the cylinder should be bored and the next oversize piston fitted (see below).

3. With a micrometer, measure the diameter of the piston perpendicular to the wrist pin at a point 10 mm above the bottom edge of the piston skirt. Compare this reading of the piston diameter with the *smallest* of the cylinder bore measurements made earlier. Subtracting the piston diameter from the smallest of the bore measurements will give the piston-to-cylinder clearance. If the measured value is more than 0.1 mm (0.0039 in.), the cylinder should be bored and the next oversize piston fitted.

If the wear has occurred primarily on the piston, fitting a new piston of the same original size you have might serve to bring the clearance into tolerance. This is, however, not often the case.

After boring, the edges of the ports should be chamfered so that there are no sharp edges

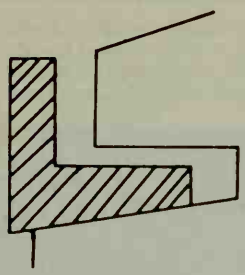
After boring, the difference between the largest and smallest cylinder bore diameters should not exceed 0.01 mm (0.0004 in.).

After the cylinder is bored, use a small file to put a slight chamfer on the edges of all the ports. This is important since rings will catch on the edges of unchamfered ports.

4. Check ring side clearance by inserting the proper size feeler gauge between the ring and the top of the ring groove. Clearance should be 0.04–0.08 mm (0.0016–0.0032 in.) for the top ring, and 0.03–0.07 mm (0.0012–0.0028 in.) for the bottom. If old rings do not have the correct side clearance, they will have to be replaced. If new rings show the wrong clearance, the piston will have to be replaced since either the ring grooves are worn (clearance too large), or have been closed up by a piston seizure. If the rings are not on the piston, roll each around the piston in its own groove as shown and check that it neither sticks nor binds in its groove.

5. Check the ring end gap with the proper feeler gauge. Refer to the "Piston Specifications" chart at the end of this section for the correct gaps for your machine.

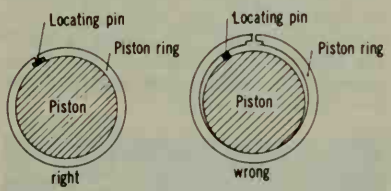
Cylinder Head, Cylinder, and Piston



ASSEMBLY

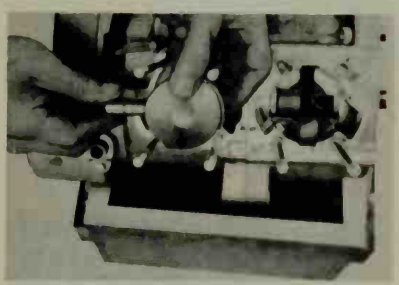
1. Assemble the piston and rings. Pistons which use keystone rings have a "K" marked on the piston crown. Keystone rings are marked with a number (1 or 2) and a letter: "1N," "2N," etc. The number is the ring position. "1" is the top ring, and "2" is the bottom ring. The rings are not interchangeable.

The RD200 uses an "L" shaped top ring.



On models with two plain rings, the chrome plated ring is installed in the TOP groove.

All rings are installed with the stamped mark facing *up*.



"L"-shaped piston ring

Spread the ring ends with your thumbs, while moving the other end of the ring down onto the piston. When the rings are in their proper groove, align the ring ends with the locating pin in the ring groove. Be sure that the rings are in this position when the piston is inserted into the bore.

Ensure that the ring ends are located on either side of the locating pin in the ring grooves (Courtesy Yamaha Int. Corp.)

2. Lubricate the connecting rod small end with two-stroke oil. Place the piston over the rod with the arrow on the piston crown pointing towards the *exhaust* port. Push the wrist pin into the piston until it is located between the snap-ring grooves.

Install the pistons so that the arrow stamped on the crown faces the exhaust port (Courtesy Yamaha Int. Corp.)

3. Install *new* wrist pin snap-rings.

4. Clean off the crankcase mating surface and fit a new cylinder base gasket. Check again to ensure that the piston is correctly installed, and the ring ends are on either side of the locating pins.

5. Lubricate the piston rings and skirt and the cylinder bore with two-stroke oil. Place the piston at top dead center. Move the cylinder down on the studs until the piston begins to enter the bore. Then carefully compress the rings with your fingers until they enter the bore. Continue moving the cylinder downward until it is seated in the crankcase.

6. Clean off the top of the cylinder. Apply some clean oil to both sides of the head gasket and install it on the cylinder. Apply a bit of oil to the threads of each of the studs.

7. Install the cylinder head; tighten the head nuts gradually and evenly in an "X" pattern until the proper torque is reached. Refer to the "Torque Specifications" chart at the end of this chapter.

8. The remainder of the procedure is the reverse of removal. Use new exhaust pipe gaskets where applicable.

ENGINE COVER ASSEMBLIES

On all models with the exception of the YM, YDS, and DS6 series, the magneto, generator or alternator is located on the left-side of the crankshaft; the clutch is on the right-side of the engine, as is the primary drive, and the countershaft sprocket is on the left.

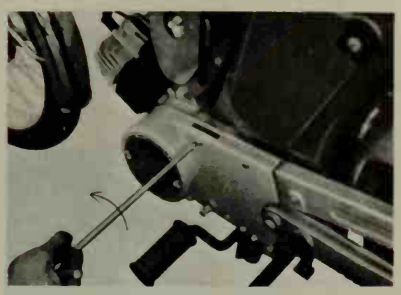
On all models so equipped, the rotary valve is located on the right end of the crankshaft.

On YM, YDS, and DS6 motorcycles, the generator is on the right, and the clutch on the left.

Before beginning work on the side cover assemblies, note the following points:

a. A puller will be needed to remove the magneto rotor, generator armature, or alternator rotor;

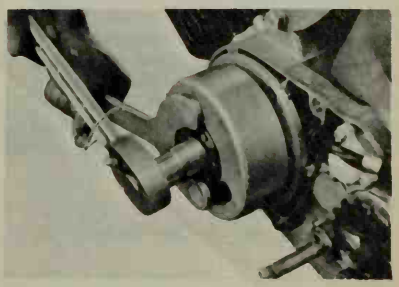
b. The clutch on all models is the wet-type. Transmission oil must be drained before removing the clutch cover. In addition, a new clutch cover gasket should be used upon reassembly;



c. All phillips head engine cover screws should be removed and installed with an impact driver. Additionally, coat the threads of engine case screws with a lubricant or anti-seize compound before installing, as this will make removal much easier the next time.

Magneto

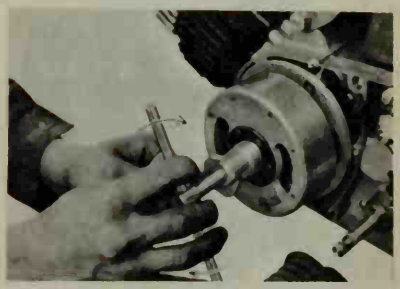
REMOVAL



1. Remove the left footpeg. Remove the gearshift lever pinch-bolt and carefully pull the lever off the splined shaft.

2. Remove the side cover securing screws and take off the cover.

Removing the left crankcase cover (Courtesy Yamaha Int. Corp.)



3. Hold the magneto rotor in place either with the special holder (if the engine is out of the frame), or by placing the transmisssion in First gear and applying the rear brake hard. Then remove the

Removing the magneto rotor nut (Courtesy Yamaha Int. Corp.)

rotor nut. An impact driver can also be used to break this nut loose.

4. Use the special puller to remove the magneto rotor. Back the puller bolt off several turns so that the puller can be threaded a good way into the rotor. Thread in the puller (left-hand thread). When it is in as far as possible, hold the puller with a wrench and turn the puller bolt clockwise until the rotor comes off the crankshaft.

Removing the rotor with the special puller (Courtesy Yamaha Int. Corp.)

NOTE: *If the rotor resists removal, tighten the puller bolt as much as possible, then give the end of the bolt a sharp rap with a hammer which should break it loose.*

CAUTION: *Do not strike the rotor itself.*

5. Unscrew and remove the stator securing screws and take off the magneto stator.

6. With a hammer and punch, remove the rotor woodruff key from the crankshaft.

INSPECTION

1. Magneto electrical tests can be found in "Electrical Systems."

2. Handle the magneto rotor carefully. Do not drop or strike it as this may decrease its magnetic properties.

3. Check the rotor for loose hub rivets or cracks. Check the inside of the rotor and note any scoring which may have been caused by contact with the stator coil cores. If such scoring exists, the cause must be determined and remedied.

4. Check the stator assembly for any damage visible to the eye such as scored coil core ends, broken or frayed wiring, loose coils, etc.

5. The tapered portion of the crankshaft should be smooth and free of corrosion, rust, etc. Finish off any scratches

or scores with fine emery cloth. Clean the area thoroughly.

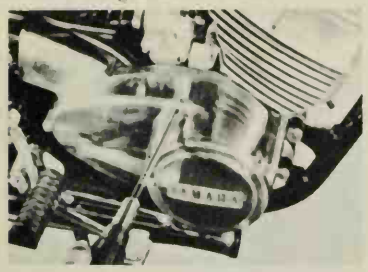
6. Check the end of the crankshaft for play which would indicate a bad crank bearing. This is one thing which would cause the rotor to strike the coil cores.

7. Check the woodruff key for condition and replace it if step-wear has taken place or if the key is too loose in the keyway.

INSTALLATION

1. Installation is the reverse of removal.

2. Do not forget to install the woodruff key. Apply some oil or grease to the crankshaft taper.



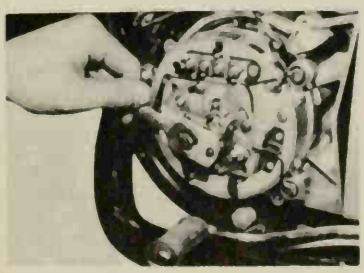
3. Push the rotor on by hand after lining up the rotor slot with the key.

4. Use the rotor nut to seat the rotor. Do not strike the rotor.

Generator

REMOVAL

1. Remove the generator cover screws and then the generator cover.



Removing the generator cover (DS6) (Courtesy Yamaha Int. Corp.)

2. Disconnect the generator wiring at the generator terminals, and the neutral switch wire (if fitted) at the connector.

Disconnecting the generator wires (Courtesy Yamaha Int. Corp.)

Removing the armature bolt (Courtesy Yamaha Int. Corp.)

3. Unscrew and remove the armature bolt and take off the timing plate. Place the transmission in gear and apply the rear brake to hold the armature if necessary. If the engine is out of the frame, secure the countershaft sprocket.

Removing the generator stator (Courtesy Yamaha Int. Corp.)

4. Remove the stator screws and take off the stator.

5. Thread a suitable bolt into the end of the armature to pull it off the crankshaft.

6. Use a hammer and punch to remove the armature woodruff key from the crankshaft.

INSPECTION

1. Refer to "Electrical Systems for component test procedures.

2. Check the woodruff key for wear and replace it if worn or loose in the keyway.

3. Inspect the generator armature for wear or scoring of the commutator segments. If the armature has been rubbing against the stator, the cause must be determined. This may be caused by an improperly mounted stator, a bent crankshaft, damaged crank bearing, etc. When the armature rotates it must not touch the stator at any point.

4. Clean up the armature with a solvent-soaked rag.

INSTALLATION

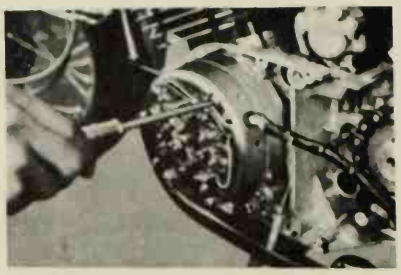
1. Installation is the reverse of the removal procedure.

2. When installing the stator, ensure that the carbon brushes are not crushed against the armature.

3. Arrange the wires so that they won't be pinched when the cover is refitted.

Alternator

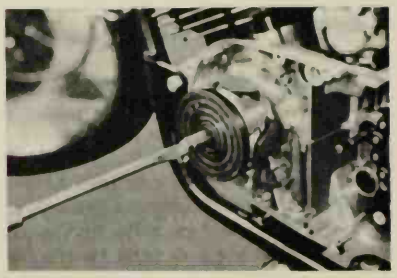
REMOVAL



1. Remove the pinch-bolt and pull the gearshift lever carefully off the splined shaft.

2. Remove the alternator cover and the crankcase side cover screws and remove the covers.

Disconnecting the alternator wires (Courtesy Yamaha Int. Corp.)

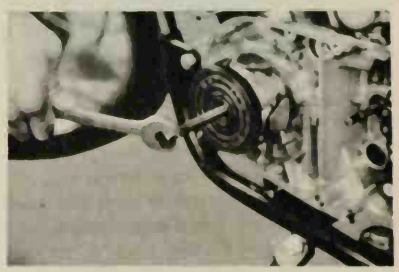


3. Disconnect the alternator wires and the neutral switch wire at the plastic couplers. On some older models, unscrew the neutral switch wire at the switch.

Removing the alternator stator (Courtesy Yamaha Int. Corp.)

4. Remove the alternator stator mounting screws and take away the stator.

5. Hold the rotor by placing the transmission in First gear and applying the rear brake hard. If the engine is out of the frame, loop a length of drive chain around the countershaft sprocket and lock the ends in a vise.



Removing the alternator rotor bolt (Courtesy Yamaha Int. Corp.)

6. Remove the rotor bolt and breaker cam.

7. Thread the special puller bolt into the rotor and pull it off the crankshaft.

8. Use a hammer and punch to remove the woodruff key from the crankshaft.

Pulling off the alternator rotor (Courtesy Yamaha Int. Corp.)

INSPECTION

1. Refer to "Electrical Systems" for component tests.

2. Check the rotor for scoring or wear which would indicate that the rotor has been contacting the stator. If this is the case, the cause must be determined. Either the stator is improperly mounted, the crankshaft is bent, or the crankshaft bearing is damaged.

3. Check the end of the crankshaft for

play which would indicate a damaged bearing.

4. Most models are fitted with rotor slip rings and these should be cleaned off with a solvent and rag.

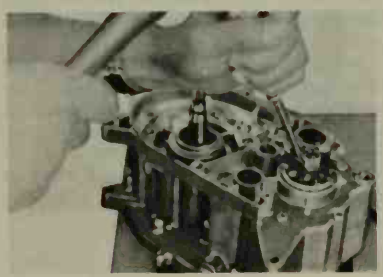
5. Check the condition and length of the carbon brushes. Replace them if shorter than the specification given in the "Electrical Systems" section or if they are worn near the limit line scribed on them.

6. Check the condition of the crankshaft woodruff key and replace it if worn or if it is a loose fit in the keyway.

INSTALLATION

1. Reverse the removal procedure to install the components. Ensure that the rotor does not contact the stator at any point.

2. When fitting the stator, be careful that the carbon brushes are not crushed.

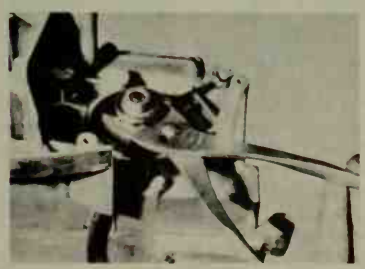


3. Arrange the wiring so that none of the wires will be pinched when the cover is refitted.

Countershaft Sprocket

REMOVAL

1. Remove the sprocket side crankcase cover.



2. With a hammer and punch, bend down the tab on the countershaft sprocket nut washer.

Bending down the locking tab on the sprocket nut washer (Courtesy Yamaha Int. Corp.)

3. Loosen the sprocket nut. If the engine is in the frame, the sprocket may be held while this is done by applying the rear brake hard. If the engine is not in the frame, loop a length of old drive chain around the sprocket and clamp the ends in a vise. Then remove the nut.

4. If the drive chain is still connected, disconnect it at this point. If a pressed-on masterlink is fitted and no chain-breaker is available, move the rear wheel all the way forward in the adjustment slots, then pull the sprocket off the countershaft. Remove the felt seal.

Removing the sprocket spacer (Courtesy Yamaha Int. Corp.)

5. Check for any spacers or thrust washers fitted behind the sprocket.

INSTALLATION

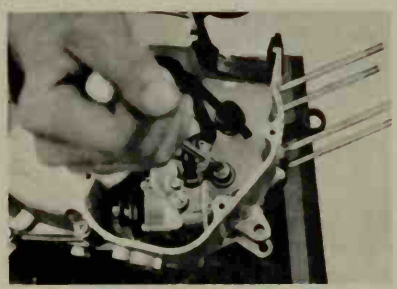
Installation is the reverse of the removal procedure. Ensure that the sprocket nut is firmly tightened and that the tab on the washer is bent up across one of the nut flats.

Clutch

Removing the clutch-side engine cover on rotary-valve models entails removing the carburetor. Refer to "Carburetor Removal" in "Fuel System" for procedures.

On all models, the oil pump may be left in place when the clutch-side cover is removed.

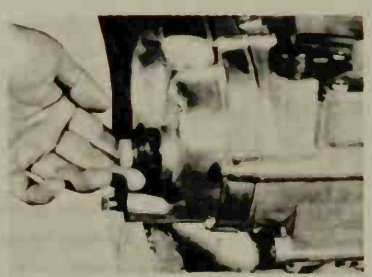
REMOVAL



1. Drain the transmission oil.

2. Remove the oil pump compartment cover.

3. Disconnect the oil feed line at the oil tank and plug the tank outlet.



4. On rotary-valve machines, remove the carburetor. Disconnect the air cleaner hose.

5. Disconnect the oil pump cable from the pump and the adjuster holder or adjuster from the cover. Disconnect the oil pump feed line(s) from the engine. On piston-port models, this is on the cylinder at the intake manifold; on rotary valve engines it is located in the oil pump compartment (see the illustration). Cover the banjo bolt(s) and washers with a plastic bag to prevent the entry of dirt.

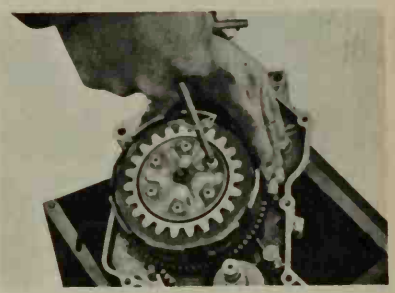
6. Remove the kick-starter pinch-bolt and carefully pull the kick-starter off the shaft.

Removing the kick-starter shaft oil seal (DS6) (Courtesy Yamaha Int. Corp.)

7. On machines which have a kick-starter shaft oil seal accessible from the outside of the cover (such as the DS6-series) remove the oil seal now.

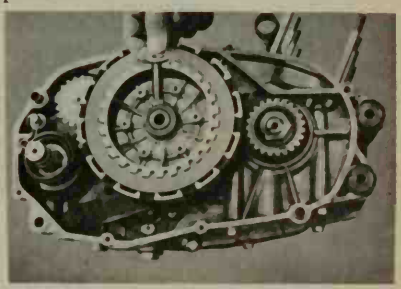
8. Disconnect the clutch cable and lever from the side cover if fitted. On most models, the cable is on the other side of the engine and can be left in place.



9. Place a drip pan beneath the cover to catch any oil residue. Loosen all of the phillips head cover screws with an impact driver and remove them. Tap around the edges of the cover with a plastic mallet to free it, if stuck, and remove the cover. Pull off the cover gasket; it should be replaced with a new one upon assembly.

10. The clutch is now accessible for disassembly and service.

NOTE: *If the primary drive (crankshaft) gear must be removed, it is advisable to loosen the primary drive gear nut with the clutch installed. Stuff a rag between the clutch and primary gears to lock them in place, then loosen the nut. Using impact rather than steady pressure on this nut will make removal easier.*

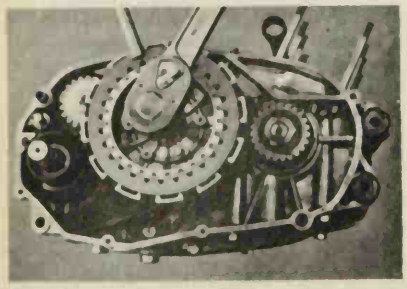


11. On centrifugal clutches only, bend in the stopper ring and lift out the ring, clutch, and friction plates. On YDS3 models, remove the clutch push crown.

12. On manual clutches, loosen the clutch pressure plate screws gradually and evenly, then remove them.

Removing the clutch pressure plate screws (Courtesy Yamaha Int. Corp.)

13. Remove the clutch pressure plate. Remove the springs; take out the pushrod.



Removing the pushrod (Courtesy Yamaha Int. Corp.)

14. Remove the clutch steel and friction plates. Note the cushion bands fitted between each pair of friction and steel plates. Handle them carefully. Note the order of the plates and bands as they are removed. All components must be installed in the same order.

15. Remove the clutch hub nut after bending down the nut washer tab with a hammer and chisel (if fitted).

To remove the hub nut, either hold the

Removing the hub nut (Courtesy Yamaha Int. Corp.)

hub stationary with the special tool, as shown, or engage the transmission and lock the countershaft sprocket in place using a method described earlier.

16. Remove the clutch hub, noting any thrust washers behind it.

17. Remove the clutch housing. The housing bushing will remain in the housing in most cases. Note any thrust washers which may be fitted to the shaft after the housing is removed.

INSPECTION

Centrifugal Clutch

Clutch plate—With the assembly mounted on the shaft, measure the clearance between the stopper ring and clutch plate. Adjust the clearance to 1.0–1.2 mm (0.040–0.047 in.) by installing replacement clutch plates of an appropriate thickness.

NOTE: *Clutch plates are available in 1.2 mm(0.047 in.), 1.4 mm (0.055 in.), and 1.6 mm (0.063 in.) thicknesses.*

Spacer—Install the bushing in the primary driven gear and check it for radial play. If any play is present, replace the bushing because it will cause premature clutch wear and excessive noise.

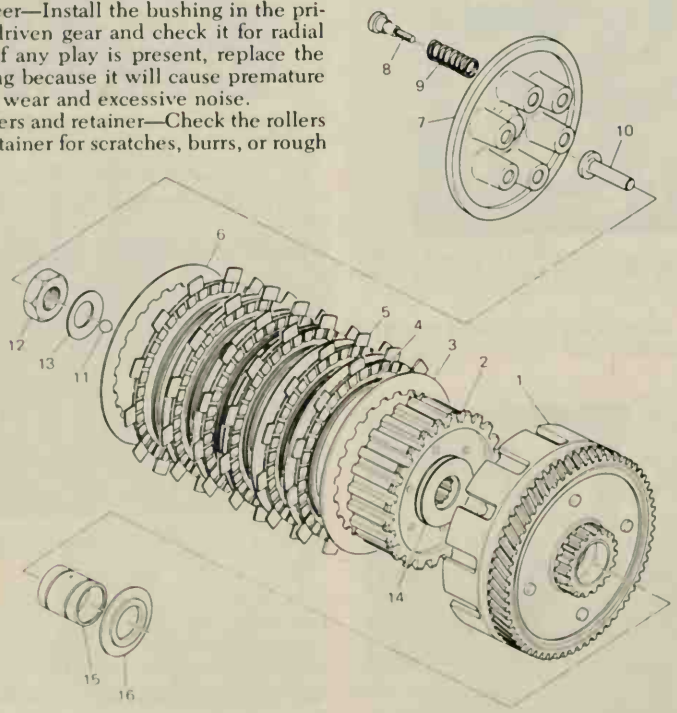
Rollers and retainer—Check the rollers and retainer for scratches, burrs, or rough spots. Place the rollers in the retainer grooves and roll them back and forth to make sure that their movement is smooth.

Manual Clutch

1. Refer to the "Clutch Specifications" chart at the end of this section for individual model specifications.

2. With a vernier caliper, check the thickness of each friction plate. If any of them is 0.3 mm (or more) less than the standard value, replace the friction plates as a set.

Clutch springs should be replaced as a set if any is 1.0 mm (0.04 in.) less than the standard free length.

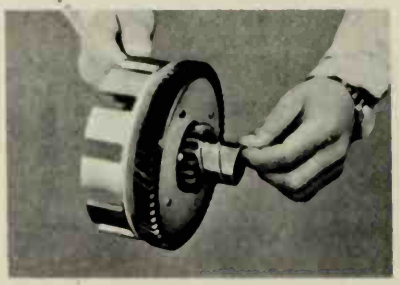


3. If any steel plate is warped more than 0.1 mm (0.004 in.) on early machines, or 0.05 mm (0.002 in.) on recent models, all of the plates should be replaced.

4. Remove the bushing from the housing and inspect both inner and outer surfaces for scoring, scratches, or wear. Remove any such imperfections with emery cloth or sandpaper. If the damage cannot be remedied in this way, replace the bushing.

5. Insert the bushing into the housing and check for play. If the clearance is excessive, replace the bushing. If a new bushing yields an excess of play, replace the housing.

6. Place the bushing on the mainshaft. If excessive play is noted here, the bushing should be replaced.



A worn or scored bushing will cause excessive clutch noise and possibly impair operation.

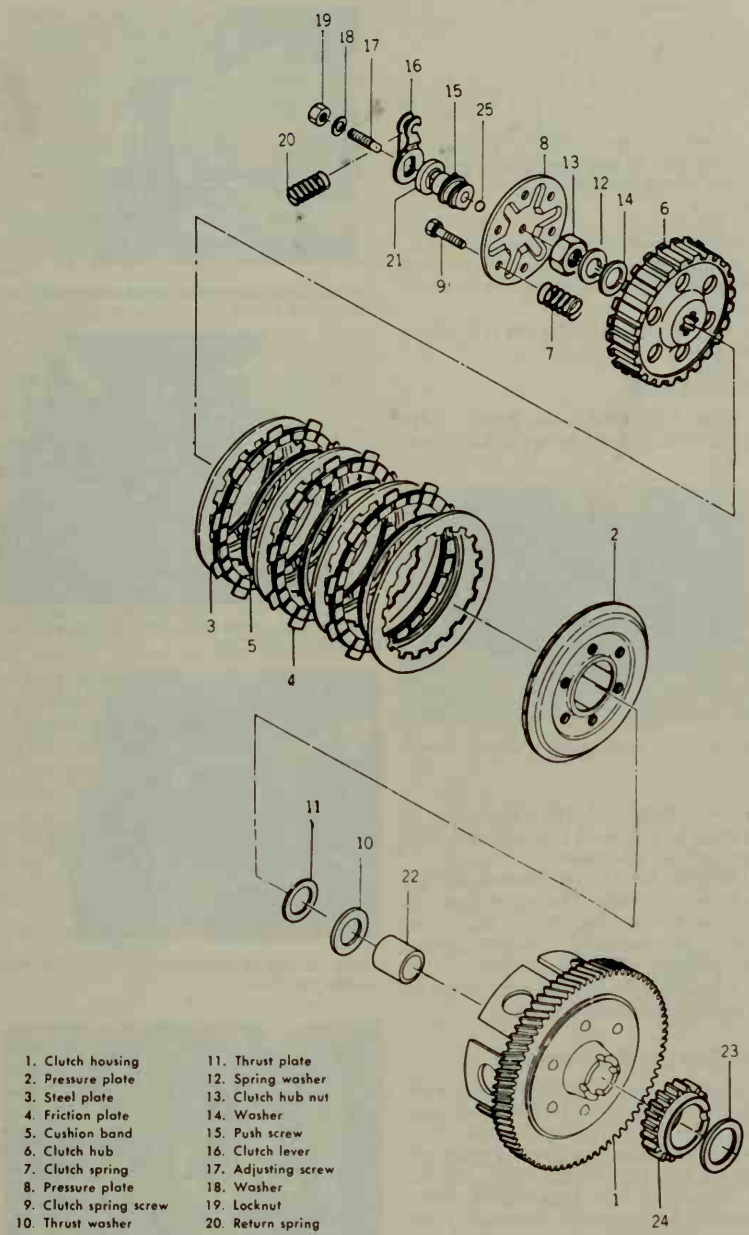
The bearing should be checked for wear, discoloration, or damage to the needles or cage, and replaced if necessary.

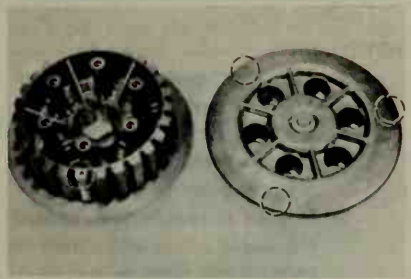
Some models may be fitted with ball bearing-mounted clutch housings. This bearing can be removed from the housing after removing its securing snap-rings. This bearing should be checked for rough or binding rotation or obvious signs of damage to the balls or races. Replace the bearing if damaged.

INSTALLATION



1. Clean all metal parts in a solvent. Lubricate them with transmission oil before assembly.

Fitting a clutch cushion band (Courtesy Yamaha Int. Corp.)



2. Install the clutch components in the reverse of the removal procedure, referring to the accompanying illustrations if necessary. Be certain that all thrust washers are correctly located. Note that the plates on the RD400 have a cut-away edge. Install the plates so that these cut-aways are about 60° apart, all around the clutch hub.

3. Be sure all of the cushion bands are in place between the friction and steel plates.

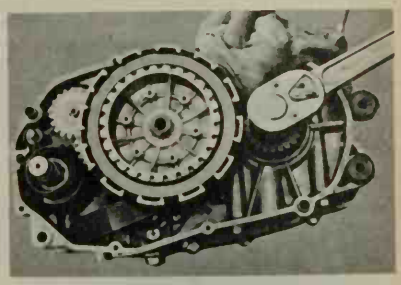
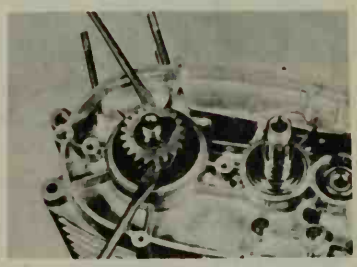
4. Tighten the clutch hub nut securely. Bend up the tab on the washer (if fitted). When installing the pressure plate, note that some models have one or more marks on the plate. Install the plate so that a pressure plate mark aligns with the clutch hub mark.

5. Clutch spring screws should be tightened gradually and evenly.



Primary Gear

REMOVAL



1. As noted, the primary drive gear nut should be loosened with the clutch installed.

2. Bend down the locking tab on the gear nut washer (if so equipped).

3. Stuff a rolled up rag between the primary and clutch housing gears to lock them in place, then remove the nut.

Removing the primary gear nut (Courtesy Yamaha Int. Corp.)

4. Some models have the oil pump drive gear mounted on the outboard side of the primary gear. This gear should be pried off with two small pry bars. Remove the woodruff key as well.

5. The primary drive gear may be secured either with splines or with a woodruff key. To remove the gear, use two small pry bars or long, thin screwdrivers.

CAUTION: *Do not use the crankcase as a lever point. Protect it with rags. Take care that the oil seal beneath the primary gear is not damaged.*

6. Remove the primary gear woodruff key from the crankshaft (if fitted), and the spacer (RD60).

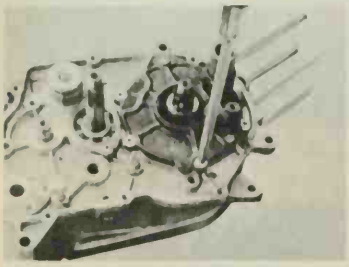
INSTALLATION

1. Reverse the removal procedure. The crankshaft should be smeared with some oil before installing the gear.

2. Do not forget to install the woodruff key.

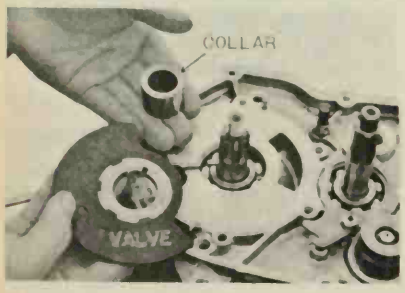
3. Tighten the primary gear nut securely, and bend up the locking tab on the washer if one is fitted.



Rotary Valve Assembly

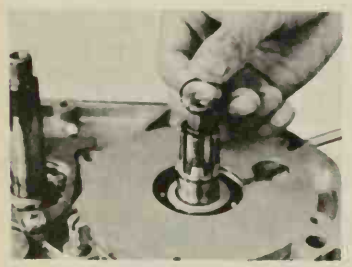
REMOVAL

1. Remove the engine side cover, pri-



mary drive gear, and clutch assembly as outlined in the preceding sections.

2. Remove the phillips head screws which hold the rotary valve cover to the engine. Carefully remove the valve cover.



Removing the rotary valve cover (Courtesy Yamaha Int. Corp.)

3. Remove the rotary valve and the rotary valve collar.

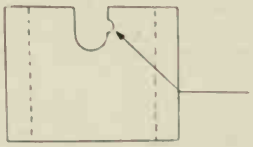
4. Remove the rotary valve locating pin from the crankshaft either by pulling it out with pliers, or by tapping it out.

CAUTION: *Take care not to damage the crankcase or rotary valve mating surfaces during this operation.*

5. Remove the O-ring from the crankshaft and discard it, a new one must be fitted on assembly.

INSPECTION



1. The rotary valve must be close to perfectly flat. If warped, replace it.

2. Inspect the valve collar for step-wear caused by the valve locating pin. Replace the collar if wear shows at this point.

3. Insert the collar into the valve. If play is excessive, replace the valve.

4. Place the collar onto the crankshaft; if play is excessive here, the collar must be replaced.

5. Remove any score marks from the collar surfaces with emery cloth. Check

for excessive clearances after polishing.

6. Check the cover oil seal for cracked or damaged lips and replace it if necessary.

7. Replace the locating pin if it is bent or damaged in any way.

INSTALLATION

1. The crankshaft and rotary valve cover O-rings should be replaced if they

Fitting the valve cover O-ring (Courtesy Yamaha Int. Corp.)

have been disturbed. The valve cover O-ring must be replaced if it will no longer fit properly in its groove.

2. Grease the O-rings thoroughly before installing them. The valve cover O-ring should be seated in the cover groove. The crankshaft O-ring should be located in the crankshaft groove.

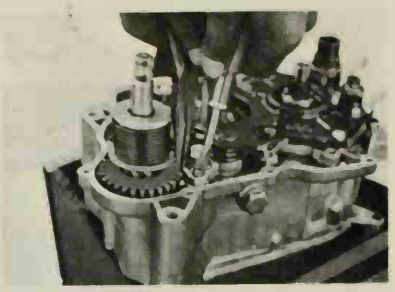
3. Grease the lips of the valve cover oil seal before installing the cover.

Kick-Starter Mechanism

On all late model machines the kick-starter mechanism can be removed (complete) from the right (clutch) side of the engine after the engine cover is removed.

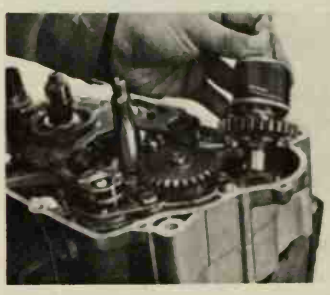
On machines such as the DS6, R3, YM, and YR-series, the kick-starter return spring can be inspected or replaced after removing the side cover. Removal of the shaft and gear, however, requires splitting the crankcases. If the cases are to be split, remove the clutch assembly, the kick-starter idler gear, and the kick-starter assembly. The clutch must be removed to remove the idler gear.

REMOVAL AND DISASSEMBLY



1. On DS6, YM, R3, and YR-series machines, remove the kick-starter return spring cover; disconnect the return spring from the case and remove it from the shaft.

2. On all late models, disconnect the kick-starter return spring from the engine and pull off the kick-starter assembly complete, if desired. Note the location of any thrust washers which may be fitted to the engine side of the kick-starter shaft.



NOTE: *If the kickstarter is to be disassembled, this is made somewhat easier by leaving the shaft in place and removing one component at a time.*

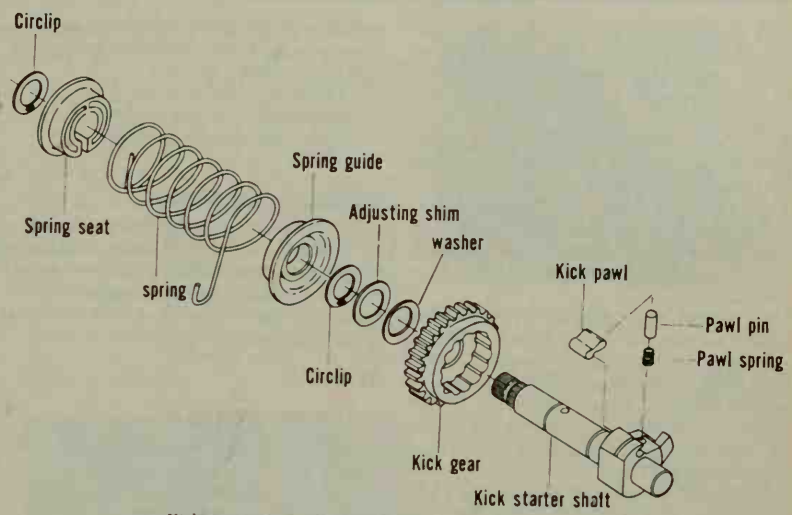
3. Remove the kick-starter idler gear circlip and remove the idler gear from the shaft. This is only necessary if the cases are to be split. The clutch assembly must be removed before removing the idler gear.

Disassembly procedures will vary slightly depending on model.

Singles (except YL2)

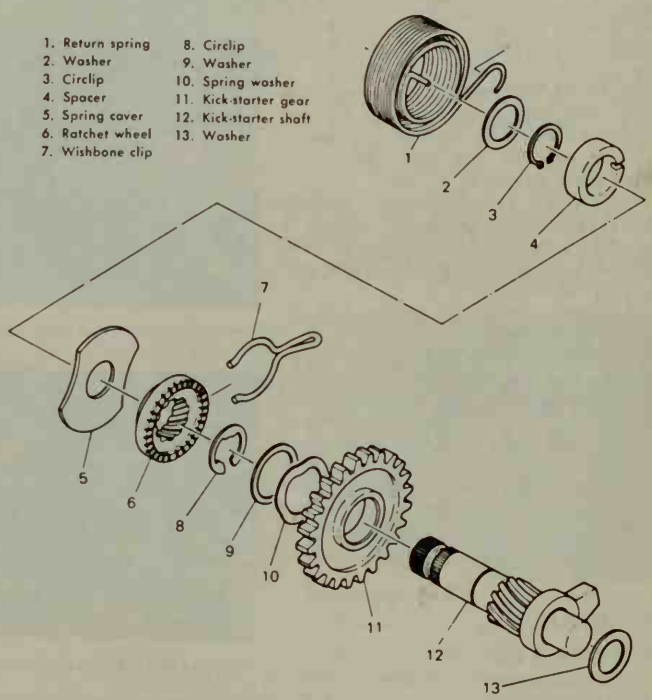
a. Remove the kick-starter shaft circlip.

b. Remove the spring cover, spring, spring guide from the shaft.



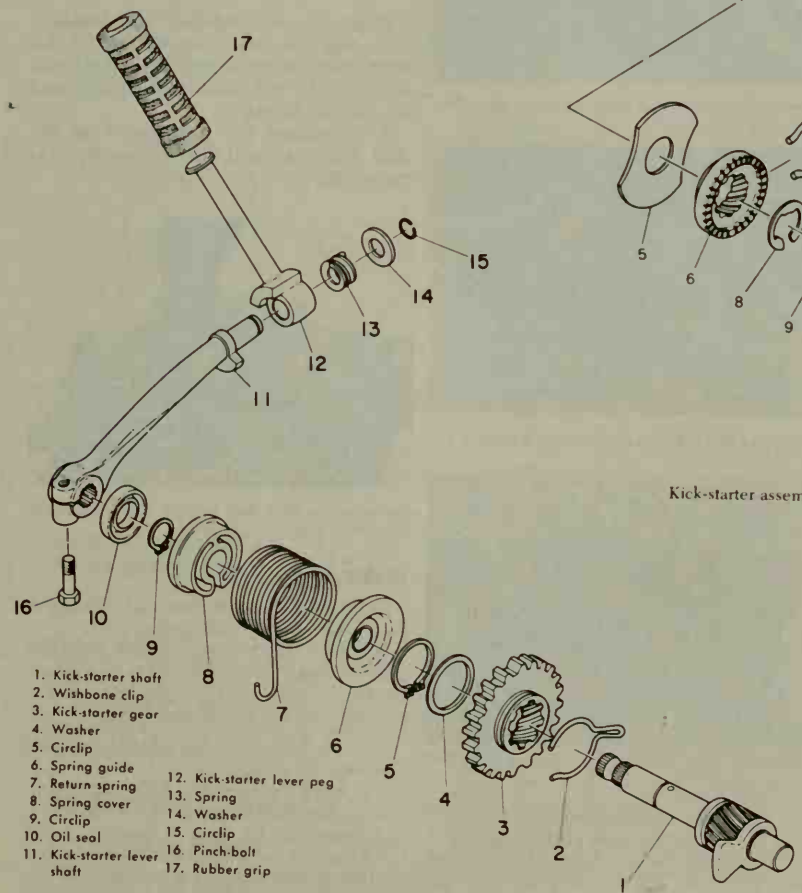
c. Remove the second circlip. Remove the shim, kick-starter shaft gear wishbone-shaped clip, and separate the kick-starter gear from the shaft.

Small Displacement Twins, YL2



a. For models such as the HS1, RD125, RD200, and CS-series, refer to "Singles," above. The same type of assembly is used.

b. On the YL1 and YL2, the procedure is essentially the same except that no wishbone clip is fitted. After removing the kick-starter gear circlip, remove the shim(s), spring washer, and slide the gear off the shaft.



CAUTION: *The gear holds down the kick pawl which is spring-loaded. Remove it carefully and note the position of the pawl pin and spring on the kick-starter shaft.*

Kick-starter assembly (YL1) (Courtesy Yamaha Int. Corp.)

Kick-starter assembly (RD250/350) (Courtesy Yamaha Int. Corp.)

Large Displacement Twins

a. On models such as the DS7 and RD250/350/400, remove the return spring.

b. Remove the shim, kick-starter shaft circlip, spacer, and spring cover.

c. Remove the ratchet wheel wishbone clip and take off the ratchet wheel.

d. Remove the shaft circlip, shim, and spring washer, and remove the kick-starter gear from the shaft.

INSPECTION

All Models

Follow the inspection procedures applicable to your model.

1. Check the splines on the kick-starter shaft. If torn, worn, or splintered to the extent that they will not hold the kick-starter lever in place, replace the shaft.

2. Check the gear teeth on the shaft. If any are broken or worn, the shaft should be replaced.

3. Check the condition of the kick-starter pawl on models so equipped. If the edge of the pawl is chipped, grooved, or shows signs of wear, it should be replaced.

4. Check the condition of the ratchet wheel on models so equipped. The inside gear teeth should be in good condition. Replace the gear if they are worn or broken. Make a close inspection of the ratchet teeth (on the sides of the gear). The gear must be replaced if these show signs of wear. If they are worn, check the condition of the ratchet teeth on the kick-starter gear in the same manner. Replace this gear as well if the teeth are worn.

5. If the kick-starter gear has a plain bore, check it for scoring and finish up any defects with a fine emery cloth. Check that the gear does not have excessive play on the shaft.

6. Check kick-starter gear teeth for wear, chipping, and other damage, and replace the gear if the teeth are damaged.

7. Inspect the kick-starter idler gear in the same ways (Steps 5–6).

8. If a pawl-type kick-starter mechanism is fitted, check the inside surfaces of the kick-starter gear. If the internal ribs are worn or chipped, replace the gear and the pawl as well.

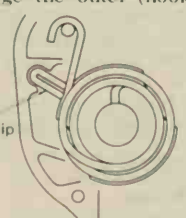
9. Check the wishbone clip and replace it if twisted or deformed.

10. Check the condition of the kick-starter return spring. If the spring has fatigued or twisted ends, it should be replaced.

11. Replace any broken or twisted circlips.

12. Check the kick-starter shaft for wear in any area a gear rides on. Insert the shaft into its bushing. If there is excessive play, either the shaft or the bushing should be replaced.

INSTALLATION



All Models

1. Installation is the reverse of the removal procedure.

2. Models using a ratchet wheel should have the extension in the ratchet wheel wishbone clip positioned in the recess in the crankcase.

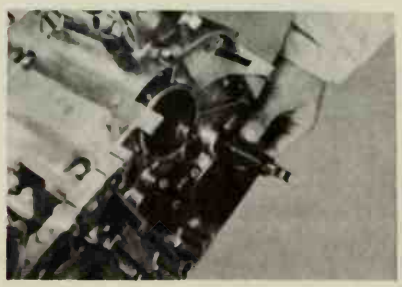
3. When installing the return spring, ensure that the inner end of the spring is inserted into the hole in the crankcase. Then turn the spring in the direction required to engage the outer (hooked) end onto its stud. The spring should have some tension in this position to hold the kick-starter lever in place.

CAUTION: *Failure to preload the spring may cause damage to the kick-starter gear during operation.*

Fit the wishbone clip into the recess in the crankcase (Courtesy Yamaha Int. Corp.)

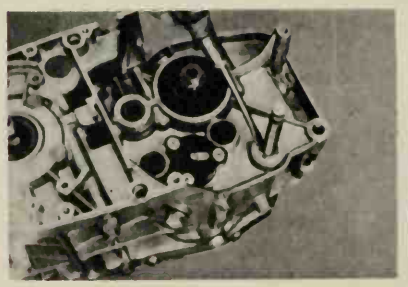
Shifter Mechanism

On most models, with the exception of YDS, DS6, YM and YR-series machines, the shift arm and shaft can be removed and inspected with the engine in the frame. On these models, a different type of shift mechanism is used.



REMOVAL

DS7, RD250/350/400, R5



1. Remove the right-side cover, the clutch, and kick-starter assemblies.

2. Remove the gearshift lever and the countershaft sprocket cover.

2. Remove the circlip and washers from the left (countershaft) side of the shift shaft. On the RD60, remove the circlip from the right-side shift linkage and remove the linkage.

3. Disengage the shift arm from the shift drum and pull the shift shaft out of the engine from the right-side.

INSPECTION

Follow those procedures applicable to your type of shift mechanism.

1. Check the splines on the gearshift shaft for wear or splintering, and replace the shaft if they are too badly damaged to properly secure the gearshift lever.

2. Check the shaft for a bent condition and replace it if bent.

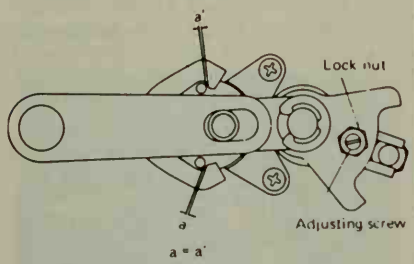
3. Check the shift arm for straightness. Check the shift fingers for straightness, and especially for wear at the tips.

4. Inspect the shifter return spring and replace it if broken, or if the ends of the spring show signs of twisting or fatigue.

5. Check the other springs in the shift

linkage and replace any that are deformed or damaged.

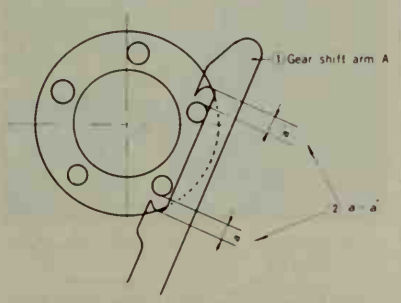
6. Inspect the shift arm roller and replace it if worn.



INSTALLATION

1. Installation is the reverse of the removal procedure.

2. When installing the return spring, be sure that both ends of the spring bear tightly against the pin. the spring ends should be parallel to one another. This will provide the tension needed to keep the (foot) shift lever in position after each shift.



3. Adjust the linkage, after installation, with the adjusting screw.

a. Place DS7 and RD250/350/400 models in Second gear;

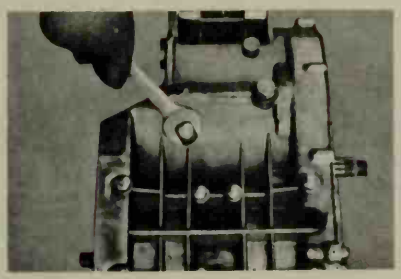
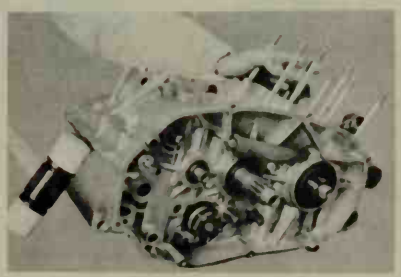
LOWER END AND TRANSMISSION



The following section deals with service to the crankshaft, transmission, shifter drum assembly, crankcase bearings and seals. Removing the engine and splitting the crankcases is necessary to service these components.

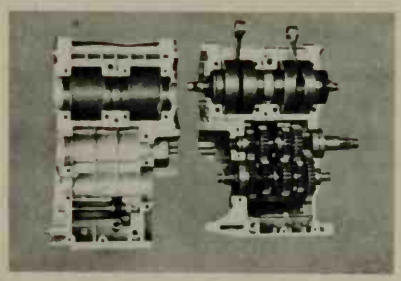
Splitting the Crankcases

LATE MODEL TWINS



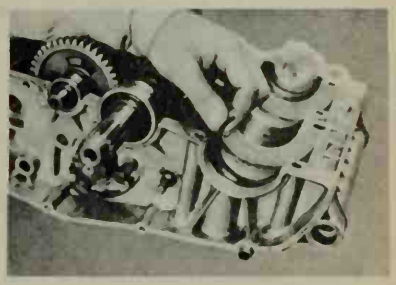
The following procedure is applicable to the DS7, R5, and RD250/350/400 models. These machines have horizontally split crankcases. No special tools are needed to split the cases.

1. Remove the engine from the frame. Remove the top end assembly. Remove the side cover components: alternator, countershaft sprocket, clutch, primary drive gear, kick-starter assembly, shift mechanism. See previous sections for procedures. Remove any bearing stopper plates which are fitted. Turn the engine upside down. The crankcase bolts are numbered. Beginning with the highest number, turn each bolt ¼ turn until all are loose, then remove them. (To assemble the cases, tighten the bolts in the same way, but begin with the lowest numbered bolt.)



Removing the crankcase bolts (Courtesy Yamaha Int. Corp.)

2. Turn the engine right side up. Tap all around the crankcase mating surface with a soft-face or plastic mallet. When the upper case comes free, remove it. The crankshaft and gear clusters will remain in the lower case half.



Splitting the crankcases (Courtesy Yamaha Int. Corp.)

3. To remove the crankshaft from the crankcase, tap upwards on one end of the shaft with a plastic mallet. Lift out the crank carefully. Note the clutch side crank bearing locating ring in the case half. Be sure that they are in place upon installation.

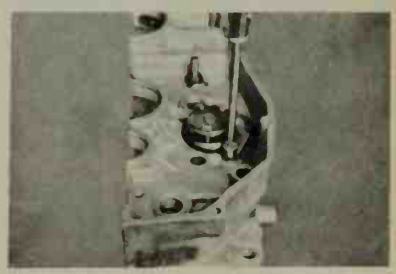
4. Inspection of the transmission gears can be carried out with the gear clusters in place. Do not remove the gear clusters unless it is necessary to do so.

5. Lift out the mainshaft, complete with gears, tapping upwards on the clutch end of the shaft with a plastic mallet to free it if necessary.

6. Remove the countershaft and gears in the same manner.

NOTE: *Check the location of the transmission shaft bearing locating rings in the crankcase: rings are found on both sides of the countershaft and the clutch side of the mainshaft. Locating rings must be in place when the shafts are installed.*



7. Before removing the shift drum and forks, mark the location of each fork so that they may be reinstalled in their proper locations.

8. Remove the neutral switch from the left-side of the shift drum.

9. Remove the shift lever guide, and the shift drum stopper plate (mounted at the right end of the shift drum). Both are secured with phillips screws.

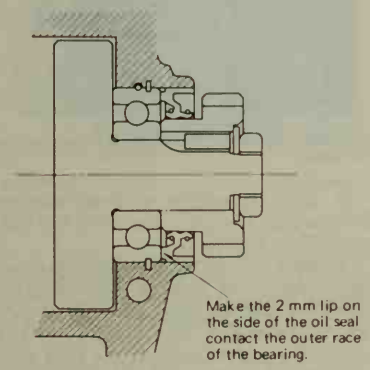
Assembly

1. Inspect the components as outlined in the sections following.

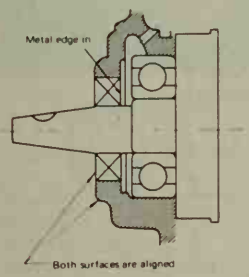
2. Note the following points upon assembly:



a. When installing the crankshaft, be sure that the bearing locating rings are in place in the cases;

b. Fit the bearing locating pin on each crankshaft bearing into the pin hole at the forward end of the crankcase;

Ensure that the bearing locating pin is fitted into the recess in the crankcase (Courtesy Yamaha Int. Corp.)



c. Crankshaft oil seals should be installed as follows: the clutch side seal should be installed so that the lip on the inner side of the seal touches the outer race of the bearing. The alternator side seal should be installed so that the outer edge of the seal is flush with the crankcase surface;

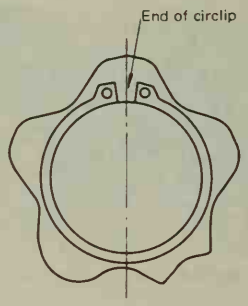
shafts, be sure that the bearing retainer rings are correctly installed in the crankcase;

f. Install the countershaft oil seal on the shaft before the case halves are assembled;



g. Lubricate the gears and the crankshaft bearings before the cases are assembled;

h. Clean the crankcase mating surfaces thoroughly then coat them with Yamaha Bond # 4;

i. Thread in the crankcase bolts and tighten them gradually in the order stamped on the crankcase until the following torque is reached:

6 mm bolts—7.5 ft lbs

8 mm bolts and nuts—15.0 ft lbs

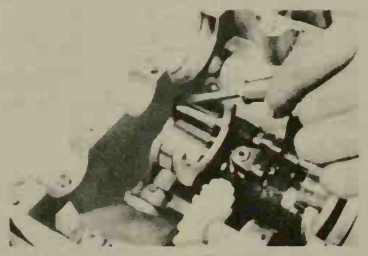
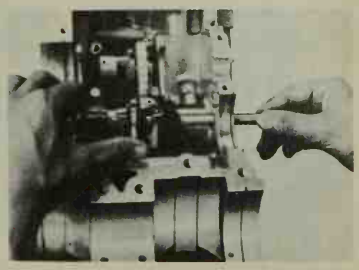
R3, YR-SERIES

1. In most respects, the R3 is similar to the DS7/R5/RD models and the procedure above should be consulted. Note the following differences:

2. When the crankcases are split, the



Crankcase components (Courtesy Yamaha Int. Corp.)



gear clusters and crankshaft will remain in the *upper* crankcase half.

3. The kick-starter shaft assembly should be removed and inspected as outlined in the "Kick-starter Mechanism" section.

4. To remove the shift mechanism, remove the two circlips which secure the shift fork shaft. One of the clips is on the right-side of the shaft and the other is inside the crankcase. Tap out the shaft and remove the shift fork.

6. Remove the four screws which secure the tachometer drive box to the upper crankcase and remove the drive box.

7. Pull out the shift drum until the shift fork cotter pin (alternator side) is accessible. Remove the cotter pin and pull out the cam follower roller with needle nose pliers.

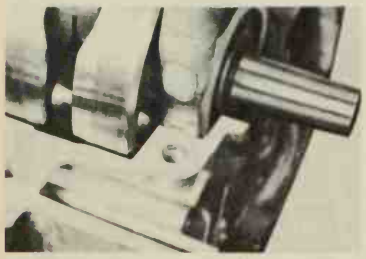
8. Remove the cotter pin and roller from the center and clutch side shift forks in the same manner, moving the shift drum as necessary to gain access to the cotter pin.

9. Remove the shift drum.

Assembly



1. Refer to the assembly section for the late model twins, above. Note the following differences:

a. The upper crankcase half is fitted with locating pins for the crankshaft bearings and the center crankshaft oil seal. When installing the crank, line up the scribed marks on the bearing races with the crankcase mating surface and ensure that each bearing locating pin is seated in its bearing. Make sure that

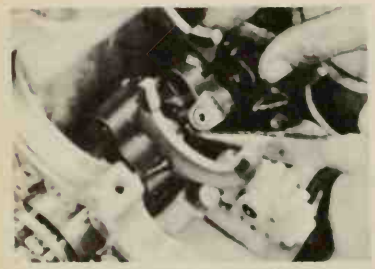
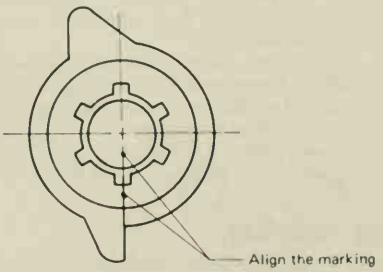
the center oil seal locating pin is fitted into the hole in the seal;
CAUTION: *Do not attempt to force the crankshaft to seat properly.*

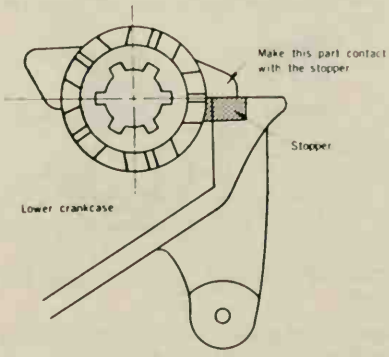


Bearing marks should be aligned with the crankcase mating surface (Courtesy Yamaha Int. Corp.)



Position the snap-ring of the right-side crank bearing so that the oil groove machined into the upper crankcase is halfway between the snap-ring ends (Courtesy Yamaha Int. Corp.)

b. Align the snap-ring on the right-side crankshaft bearing so that the oil groove machined into the upper crankcase half is halfway between the snap-ring ends;



Bend down the ends of the cotter pins so that they will not touch the shift forks or crankcase when the forks move (Courtesy Yamaha Int. Corp.)

c. When installing the shifter mechanism, bend down the ends of the cotter pins so that they will not touch other forks or the crankcase when the forks move. Check clearances by shifting the gears by hand. New cotter pins should always be used.

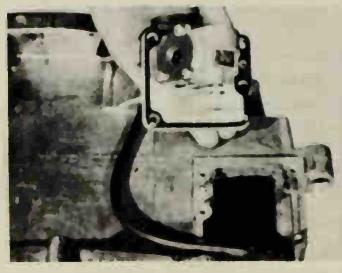
d. When installing the kick-starter mechanism, fit the ratchet wheel onto the shaft so that the punch marks align. Install the shaft into the crankcase so that the ratchet wheel arm bears against the stopper in the lower crankcase half;



e. Adjust the shifter mechanism with the adjusting screw so that the fingers of the shift arm are equidistant from the pins on the shift drum.

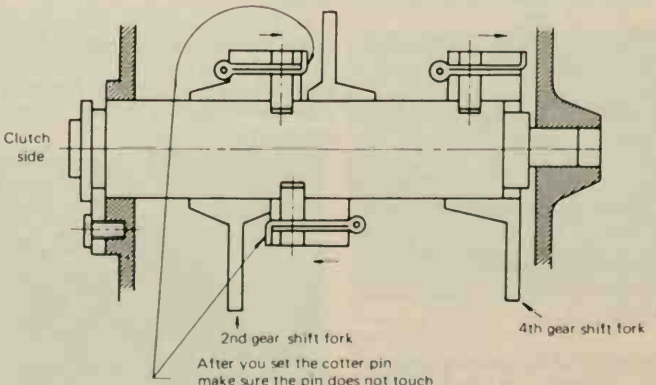
EARLY TWINS

The following procedure is applicable to machines such as the DS6, YDS, and YM-series. A special jig is needed to split the cases, which are vertically mated. Another shop tool is required to seat the crankshaft in the crankcase.

1. Remove the engine from the frame; remove the top end, clutch generator, kick-stater, and primary drive assemblies.

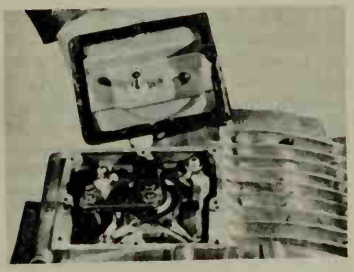
2. Remove the four phillips head screws which secure the tachometer drive box on top of the crankcase.

Tachometer drive box removed (Courtesy Yamaha Int. Corp.)



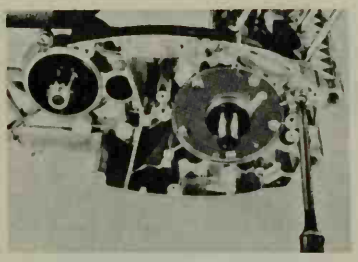
3. Turn the engine over and remove the gearshift linkage cover from the bottom of the crankcase.

4. Stuff a clean rag into the crankcase around the shift linkage. Carefully remove the clip securing the shift arm to the cam assembly. Remove the washer and spring and disconnect the shift arm.



5. Remove the phillips screws, and lift out the shifter cam assembly.

6. Remove the shift shaft circlip and pull the shaft out of the cases.



7. Mark the shift forks for position so that they may be installed in the same locations.

8. Remove the shift fork shaft circlips on the outside of the crankcase. Push the shafts in, then remove the shaft circlips on the inside of the case.

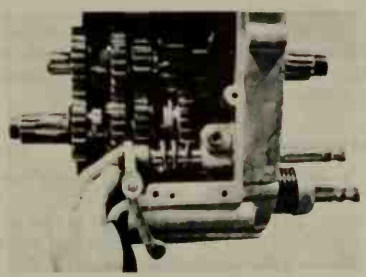
9. Pull out the shafts and remove the shift forks.

10. Remove the crankcase screws in the right crankcase half. Two of the screws have rubber caps. Be sure they are in place when reassembling the engine.



11. Secure the crankcase splitting jig in place. Threaded holes are provided. Tighten the bolt while tapping lightly around the case mating surface and on the end of the countershaft with a plastic mallet. Separate the cases evenly.

12. The crankshaft and transmission shafts will remain in the left crankcase half, as will the kick-starter shaft.

13. To remove the crankshaft from the case, fit the crankcase splitting jig to the left case half and press out the crankshaft.

14. Check the gear clusters in place. If removal is required, tap lightly on the ends of the shafts with a plastic mallet and remove the shafts together from the cases.

15. To remove the gearshift shaft assembly, remove the shaft circlip from the outside of the left crankcase half and pull out the shaft.

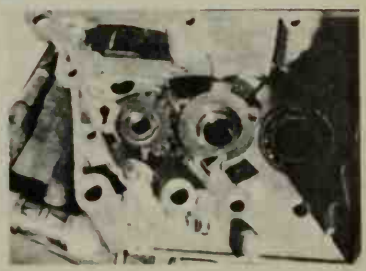
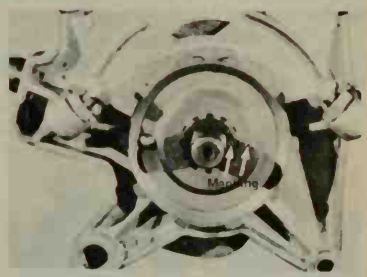
16. Remove the kick-starter shaft circlip on the outside of the crankcase after removing the spring cover and return spring. Pull the shaft out from the inside of the case.



17. Refer to component inspection procedures below.

Assembly

1. Assembly is the reverse of the disassembly procedure. Note the following points.



2. Install the crankshaft in the right-side crankshaft half using the special tool. Engage the kick-starter ratchet gear with the kick-starter gear. After the gear clusters are installed, install the shift forks to the gears and slide in the shift fork shafts. Secure them with the snap-rings.

3. When ready to assemble the cases, coat the mating surface of the right-side crankcase with Yamaha Bond #5. Tap the cases together with a plastic mallet with the con rod at top dead center.

4. When assembling the shifter mechanism, align the punch mark on the shift cam splined shaft with the mark on the shift cam.

5. Place the transmission in Neutral then install the cam in the engine. Install the shift arm, fitting a spring, washer, and clip to the end of the shift arm. Adjust the shift linkage so that with the stopper ball engaged in the cam stopper notch, the gap between the pawl and stop is about 1 mm.

6. Use a new gasket on the gearshift linkage cover.

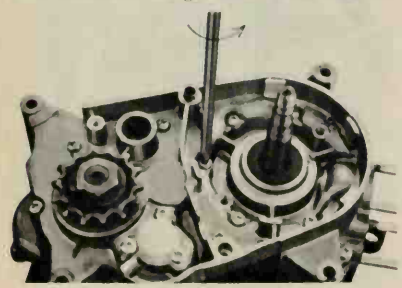
SINGLES AND SMALL DISPLACEMENT TWINS

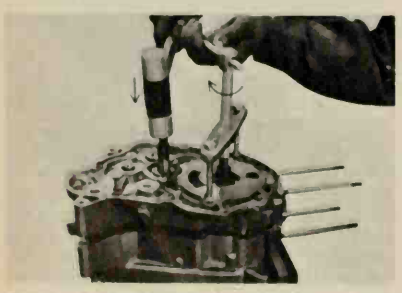
The following procedure is applicable to all machines with vertically mated crankcases. Examples: G-series, RD60, YL, YA, YAS, AS2, RD125, YCS, RD200, HS1, 1-S2, and CS-series machines. A jig to separate the cases is needed.

1. Remove the engine from the frame.



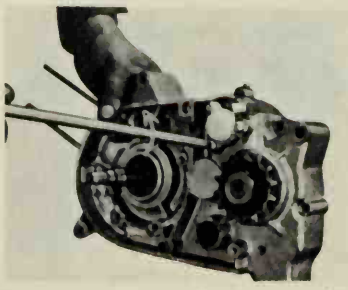
2. Remove the top end; remove the left and right-side covers, clutch assembly, primary drive gear, electrical generator, countershaft sprocket, shift arm, kick-starter shaft and gears, rotary valve (if fitted), etc.

3. Remove the gearshift drum stopper spring and lever.



4. Unscrew and remove the crankcase screws in the right or left crankcase half. Fit the crankcase separating jig to the right case half, and tighten the jig bolt, while tapping lightly on the end of the countershaft sprocket with a plastic mallet. Separate the cases gradually and evenly.

5. The crankshaft and transmission components will remain in the left case half.



6. Remove the gearshift drum neutral

switch. Remove the neutral stopper bolt, spring and plunger from the top of the case half.

7. Remove the shift drum circlip, washer, and keeper.

8. With a plastic mallet, tap out the countershaft while holding the shift drum and mainshaft. The transmission and shift mechanism should be removed as an assembly.

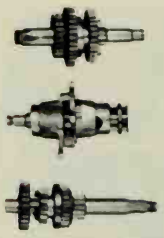
9. Fit the crankcase splitting tool to the left case half and use it to press out the crankshaft.

10. Refer to component inspection procedures, below, for service work on the crank, bearings or seals, transmission or shifter.

Assembly

1. When assembling the cases, note the following points:

a. Draw the crankshaft into the left case half with the special puller, while holding the connecting rod at TDC;



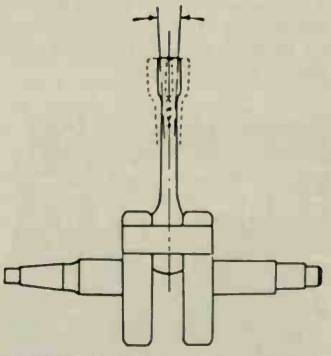
Pulling the crankshaft into place (Courtesy Yamaha Int. Corp.)

b. Assemble the shift drum and gear clusters as an assembly. Be sure that the shift drum is positioned in Neutral while refitting the assembly to the cases;

c. Coat the mating surface of the left case half with Yamaha Bond #4. Join the cases with care. Tighten the crankcase screws securely.

CAUTION: *Do not use the crankcase screws to force the cases together. They should be tightened only after the cases have been mated.*

Shift drum and gear clusters assembled (Courtesy Yamaha Int. Corp.)



Crankshaft

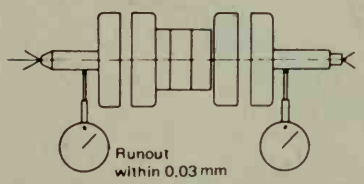
1. Crankshafts on all models are pressed together. To disassemble any crankshaft (which would be necessary in the event of a bent connecting rod, worn big end bearing, or worn inner crank bearings on twins), a special tool is needed.

2. Lubricate the big end bearing with two-stroke oil. Rotate the rod slowly around the crankpin. The movement should be smooth and noiseless.

3. With the crankshaft mounted in a jig, and a dial indicator mounted to bear against the small end of the connecting rod, check the lateral movement of the small end. It should not exceed 2.0 mm (0.08 in.). If the movement exceeds this figure, the con rod big end bearing is worn, and it must be replaced.

When new, rod small end movement should be 0.8—1.0 mm (0.032–0.04 in.).

Small end lateral play is an indication of big end bearing wear (Courtesy Yamaha Int. Corp.)



Checking big end side clearance with a feeler gauge (Courtesy Yamaha Int. Corp.)

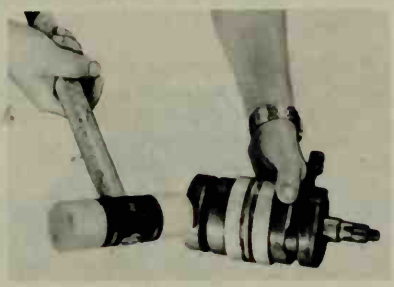
4. Check the connecting rod big end side clearance with a feeler gauge placed between the rod big end and one of the flywheels. Side clearance should be 0.1–0.3 mm (0.004–0.012 in.) (RD400: 0.25–0.75 mm/0.01–0.03 in.). If side clearance exceeds this figure, the crank should be disassembled and inspected.

5. Mount the crankshaft in a set of V-blocks, and attach dial indicators to each end of the crank and to the center main bearing on twins.

Rotate the crank slowly and note the indicator readings. The maximum allowable run-out is 0.03 mm (0.0011 in.) (RD400: 0.05 mm/0.002 in.). If run-out exceeds this figure, the crankshaft is either bent, or the flywheels are out of alignment.

Checking crankshaft run-out with dial gauges (Courtesy Yamaha Int. Corp.)

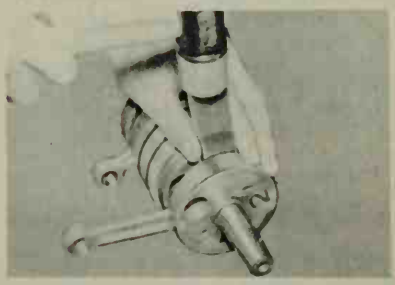
6. The following procedure concerning crankshaft truing should only be undertaken by an experienced mechanic. The information is supplied, however, for the purpose of providing general information.



NOTE: *The procedure is written for single-cylinder machines. It is, however, applicable to twins as well, if each side of the crank is treated as a "single" first: check alignment and run-out of each side; then overall alignment.*

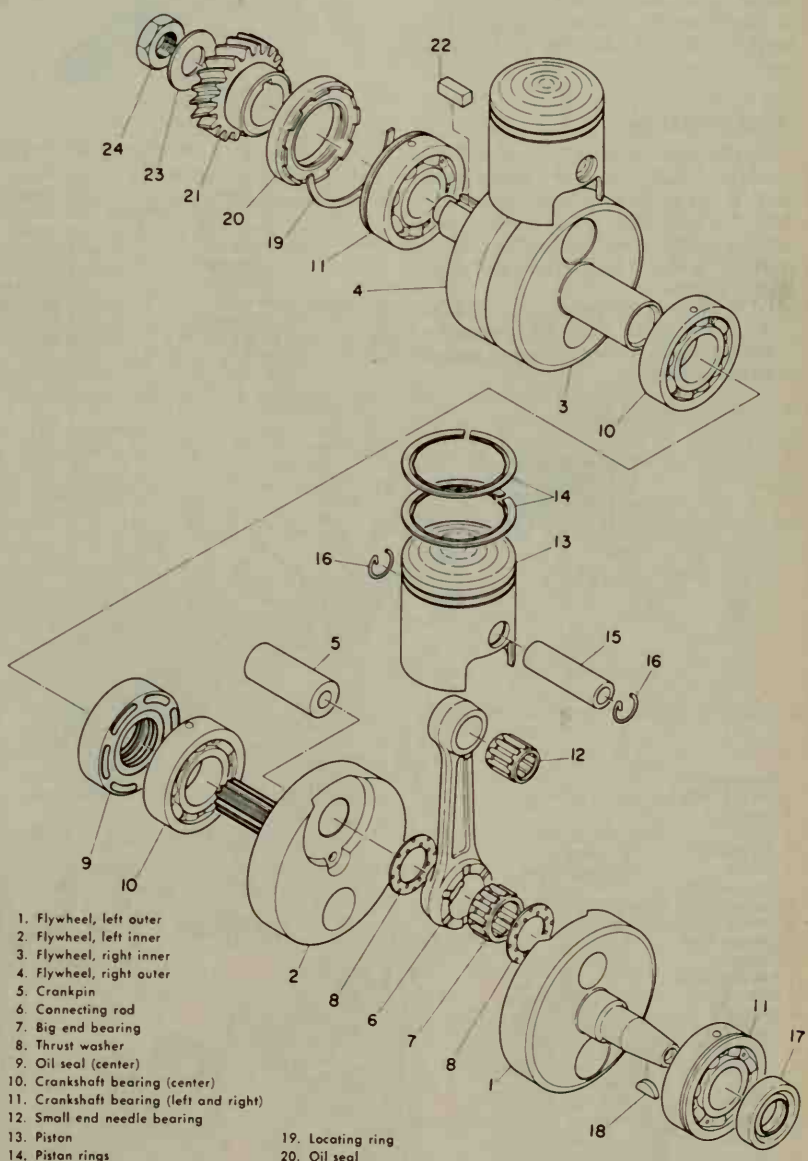
7. The crankshaft must be checked for eccentricity and for parallel flywheels. The crankshaft flywheels are eccentric if one has been rotated slightly ahead of the other. The flywheels are nonparallel if they lean towards or away from each other.

8. Turn the crank in the jig. If the dial gauges do not move the same distance, and do not begin and end their movement at the same time, the crankshaft flywheels are both eccentric and nonparallel. In this event, eccentricity must be taken care of first.



9. To correct eccentricity, rotate the crank until the drive-side dial guage indicates the high point of its travel. Stop at this point. Imagine a line drawn from one of the dial gauge shafts to the other. Mark the spot on the drive-side flywheel at the spot this line would cross it. Remove the crankshaft from the aligning jig, and, with the brass hammer, strike this spot on the drive-side flywheel smartly. Be sure you are holding the crank assembly by the generator/magneto-side shaft while doing this. Recheck alignment, and repeat this procedure as long as necessary until the dial gauge needles begin and end their travel at the same time.

10. Replace the crankshaft assembly in the jig, and rotate it until the needles reach their highest point of travel. If the crankpin lies along an imaginary line drawn between the ends of the two dial gauge shafts, the flywheels are evidently pinched together opposite the crankpin.



Aligning crankshaft flywheels (Courtesy Yamaha Int. Corp.)

To correct this condition, insert a wedge, preferably of wood or soft metal, between the flywheels at a point opposite

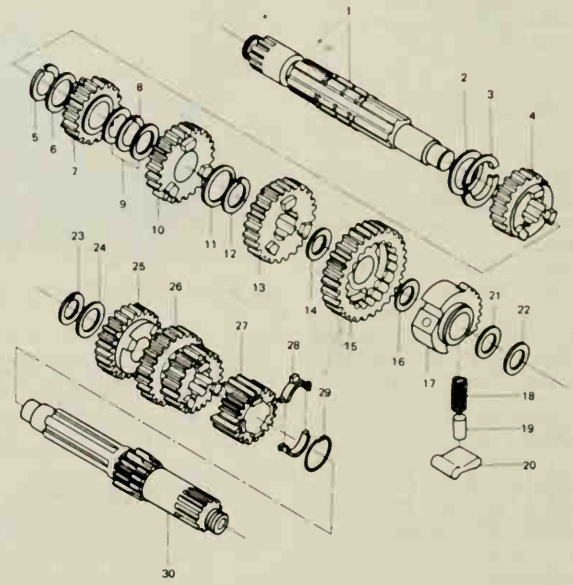
Crankshaft assembly (Courtesy Yamaha Int. Corp.)

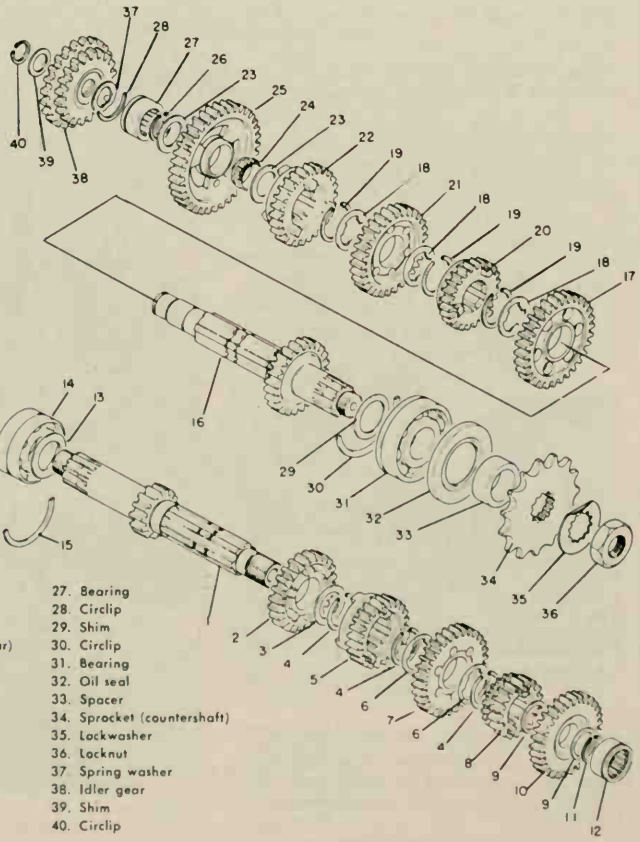
the crankpin, and, supporting the crank in one hand, strike the wedge with a hammer to spread the flywheels apart. Continue until the flywheels are parallel within specifications.



11. If, when checking for parallelism, the crankpin was *not* along or near the line drawn between the ends of the dial gauge shafts, if it was opposite this line, then the flywheels are too far apart, opposite the crankpin. In this case, once again make a mark on either flywheel where the imaginary line would cross it. (Note that the crank should be positioned so that the dial gauges are at the highest point of their travel). Remove the crank, and, with the brass hammer, strike the flywheel sharply on the *side* to bring the flywheels closer together. Check again, and repeat the procedure until crank runout is within specification.

12. Clean the crank assembly thoroughly, and oil the big end bearing well.

Transmission



1. The gears should not be removed from their shafts unless absolutely necessary. If the gears are being removed, be sure that each gear, thrust washer, shim, and snap-ring is laid out in the order of removal so that it can be installed in the proper location.

NOTE: *When referring to the exploded diagrams, note that the number of thrust washers may vary for individual machines.*

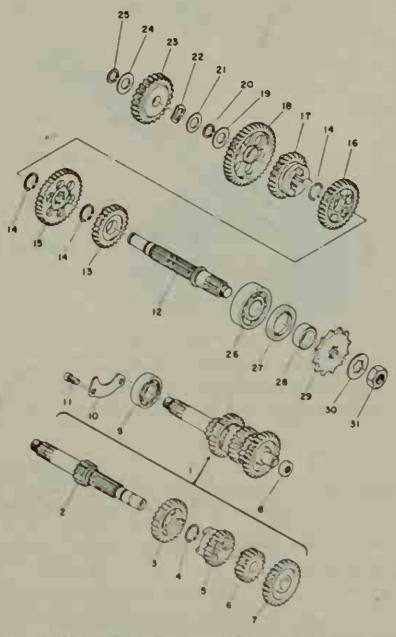
3. Check the inner splines on those gears so equipped, and replace the gear if the splines are worn or broken. Inspect the corresponding splines on the shafts. The shafts should be replaced if damaged.

4. Inspect the engaging dogs on gears which have them. The dogs must not be worn, chipped, or broken. Replace the the gear if they are.



5. Inspect the transmission shafts for damage to the sprocket nut threads, and wear or damage to the clutch gear, or sprocket splines. Make sure that the shafts are not bent. Inspect the shaft bearings (see below).

Shift Drum

1. The shift drum itself should be inspected for wear in the shift fork cam follower pin grooves, wear to the cam plate, and scoring or wear of the bearing surfaces.

2. The shift fork shafts should be inspected for wear in those areas on which

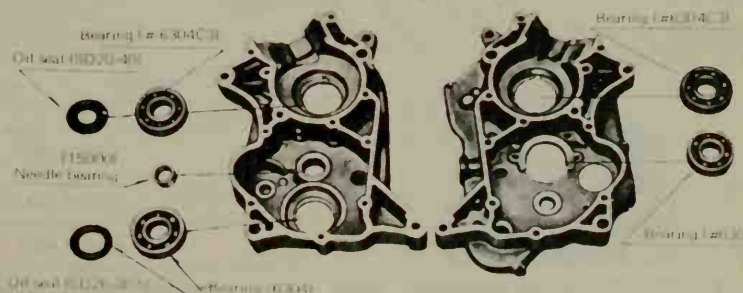
the shift forks ride. Roll the shafts along a flat surface to check them for a bent condition. Replace the shafts if bent.

3. Check the shift forks themselves. Note any wear to the fork bore. Check the fingers for bends, or for chipping or wear. Replace any fork on which such defects are noted.



4. Check the shift fork cam follower pins for wear, and replace them if damaged.

5. Check the shift drum dowl pins. Replace any broken, worn or missing pins.

Bearings and Seals

1. Bearings can be checked in place, whether on the crankshaft or still in the cases.

2. Lightly lubricate the bearing in

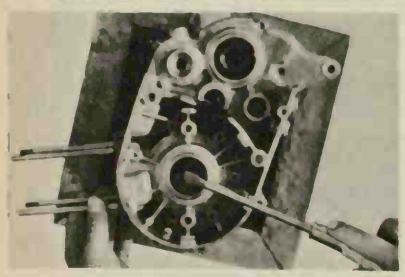
question with some two-stroke oil, and rotate it slowly. Movement must be smooth, effortless, and quiet.

3. If the bearing movement is halting, or noisy, the bearing should be replaced.

4. Check the general condition of the bearing in place, if possible. Note any damaged bearings or scored races.



5. If the bearings must be replaced, note the following:

a. Crankshaft bearings should be replaced in sets, along with the oil seals. Outer bearings on twins can be removed from the crankshaft with a puller, but renewing the inner crank bearing requires splitting the crankshaft;

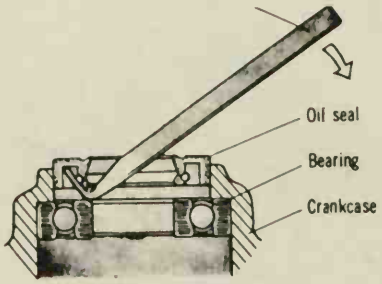
b. Bearings, either crankshaft or transmission, which remain in the crankcases can be removed after taking away any bearing retainer plates, snaprings or oil seals which are fitted;

Prying out a crankshaft bearing oil seal (Courtesy Yamaha Int. Corp.)



c. Bearing removal from crankcases is facilitated by gently heating the crankcase around the bearing boss. Tap out the old bearing, and drive new ones straight in (after heating the case) with a bearing driver, or a sturdy block of wood.

6. Oil seals should be replaced as a matter of course. Oil seals can be pried out of the cases with a screwdriver using a block of wood as a leverage point. Alternately, use a hooked tool to remove the seals. Seals with damaged or torn lips must be replaced.

7. Once seals are removed, they should not be reused for any reason.

Removing an oil seal with a hooked lever

8. Upon assembly, lubricate the bearing before installation with the type of oil usually supplied to it (i.e., either transmission or two-stroke oil). Grease the lips of all oil seals before inserting any shafts into them.

Oil seal installation

9. Where applicable, all bearings and seals should be installed with the manufacturer's mark facing outward.

LUBRICATION SYSTEM

All of the Yamahas covered in this section use the "Autolube" automatic oil injection system.

The Autolube system includes an oil reservoir, oil feed line, oil pump, and oil delivery lines. The pump is of the plunger type and is driven by the crankshaft or clutch (early models) through reduction gears. The amount of oil fed to the crankcase delivery line is determined by two variables—the speed of plunger operation and the length of plunger stroke. These variables are set by the engine rpm and the degree of throttle opening, respectively. The pump effectively meters the amount of oil according to engine speed and load and, as a result, no more and no less than the required amount is consumed. The pump also houses a check valve that keeps the oil output pressure constant and seals the delivery line when the engine is not operating.

The lubrication system is virtually maintenance-free except for checks on the oil pump cable adjustment (covered in the "Maintenance" section), the minimum pump stroke setting (see below), and pump bleeding (necessary only if the Autolube tank has run dry, or the oil lines disconnected for any reason).

Oil pump (Courtesy Yamaha Int. Corp.)

OIL PUMP

The oil pump must never be disassembled for any reason. To do so will render the pump unserviceable. If lubrication problems are traced to the pump, it must be replaced with a new one.

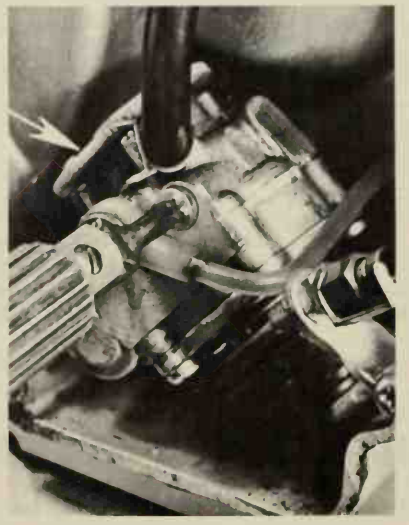
Removal and Installation

1. Remove the oil pump cover.
2. Disconnect the pump cable from the adjusting pulley. Disconnect the oil tank-to-pump line and plug it to avoid oil loss.
3. Disconnect the pump-to-engine line(s). These may be either simple hose fittings or banjo fittings secured with a screw and sealed with gaskets on either side of the banjo.

CAUTION: *If oil pump inlet and outlet fittings are identical, mark the location of each hose before disconnecting it, so that the hook-ups will be correct when the pump is refitted. If banjo fittings are used for the outlet lines, take care that the gaskets are not misplaced.*

4. Remove the securing screws and remove the pump.

Removing an oil pump banjo bolt



5. Cover the oil line ends with small plastic bags secured by rubber bands to prevent the entry of dirt or other foreign matter in the event that the pump will be out of the machine for some time.
6. Check the condition of all oil lines. Replace any that are cracked, torn, or which show signs of damage. Check the banjo gaskets for condition and replace them if cracked.
7. The oil pump mating surface may be fitted with either an O-ring or a gasket, and this item should be replaced each time the pump is removed.
8. Installation is the reverse of the disassembly procedure. Ensure that all hose fittings are correct. Do not overtighten banjo connection screws.
9. After installation, turn the throttle twist-grip from closed to full open. Note that the guide pin should not touch the adjustment pulley at any point in its travel.
10. Before starting the engine, bleed the pump (see below), adjust the pump cable and minimum stroke.
11. When replacing the oil pump cover, ensure that it does not pinch any oil lines.

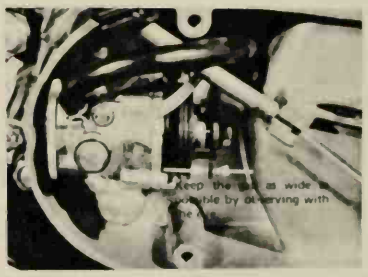
Bleeding

As noted above, bleeding the pump is necessary any time that the oil pump has been removed from the machine, whenever any of the oil lines has been disconnected, or if the Autolube tank has been drained or run dry.

Before beginning, ensure that the oil tank has a sufficient supply of oil.

1. Remove the oil pump cover. Place a suitable receptacle beneath the oil pump compartment to catch the drained oil.
2. The pump is equipped with a plastic starter plate on one end. This is used to bleed the system.

Loosening the oil pump bleed screw. The arrow indicates the pump starter plate



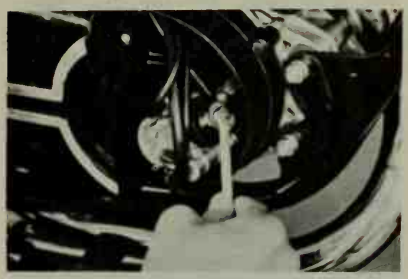
3. Loosen and remove the bleeder screw on the pump body.
4. Open the throttle fully and hold it open during the bleeding operation.
5. With your other hand, turn the starter plate in the direction of rotation indicated by the arrow on the plate.
6. Continue turning the starter plate while observing the flow of oil from the bleeder hole. When the oil is completely free of air bubbles, replace and tighten the bleeder screw. The system has now been bled.
7. After this operation has been completed, start the engine and allow it to idle for a few seconds while holding the oil pump open with the cable. This is only necessary on newly rebuilt engines to ensure sufficient lubrication during the first moments of operation. If the pump is held open too long, the plug(s) may foul.
8. After bleeding, check the pump minimum stroke and the cable adjustment.
9. If the bleeding procedure does not work (i.e., air bubbles continue to come out of the bleeder hole), check for air leaks at the hose junctions. With the engine running, squirt some clean Autolube oil at the hose connections. If bubbles form, there is an air leak at that point.

Minimum Oil Pump Stroke

Before beginning, have a feeler gauge of the correct size at hand. The minimum pump stroke on most recent models is 0.20–0.25 mm (0.008–0.010 in.), although on some older models it is slightly greater. Refer to the specifications chart at the end of this section for the correct minimum pump stroke for your machine.

Note the following terms: the *starter plate* is the plastic disc at one side of the oil pump and is used to operate the pump by hand. The *adjustment pulley* is that to which the oil pump cable is attached. The *adjustment plate* is the small plate at the opposite end of the pump from the starter plate. It is secured by a locknut.

1. Remove the oil pump cover plate. Make sure that the throttle twist-grip is fully closed.
2. Slowly turn the starter plate by hand in the direction of rotation indicated by the arrow on the plate. As the starter plate is turned, a gap will be created between the adjusting plate and the adjusting pulley. Continue to turn the starter plate until this gap is at its maximum width. This can be done by gauging the gap with your eye.



Turn the starter plate slowly until the gap between the adjusting plate and pulley is as wide as possible (Courtesy Yamaha Int. Corp.)

Checking the minimum oil pump stroke with a feeler gauge inserted between the adjusting pulley and plate

3. Insert the correct sized feeler gauge between the adjusting pulley and the adjusting plate. The clearance between the two should be within the specification shown for the individual models in the chart.

Removing the adjusting plate locknut (Courtesy Yamaha Int. Corp.)

4. If the clearance is not correct, remove the adjusting plate locknut, then the adjusting plate. Add or remove the 0.1 mm adjusting shims (supplied for this purpose) to the oil pump shaft to correct the adjustment, then refit the adjusting plate and tighten the locknut securely. Recheck the clearance.

NOTE: *If the original adjusting plate to pulley clearance was too great, remove a shim; if it was too small, add a shim or shims.*

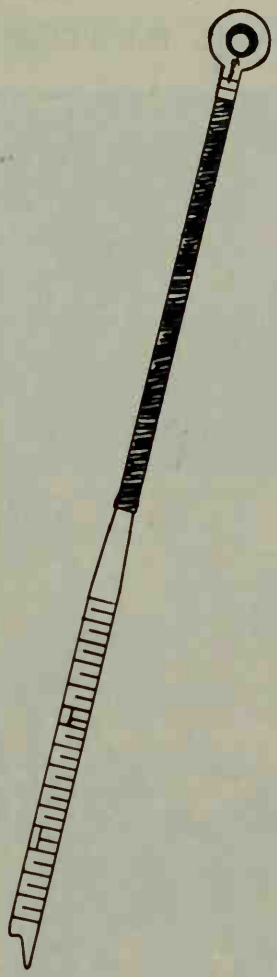
Pump Output Check

1969, 1970 AND 1971 MODELS AND RD400

The delivery output of the oil pump should be measured on the above models after all other possible causes of trouble have been eliminated (see "Troubleshooting," below).

Needed for this operation are: a laboratory tube graduated in cubic centimeters, and an extra oil pump-to-engine delivery line.



NOTE: *This check can be performed with the pump mounted on the bike or on a bench.*

1. Cut one end off the extra delivery line and slide it over the end of the graduated tube (see the illustration).

2. Disconnect the oil pump delivery line banjo bolt and connect the extra one in its place with the graduated tube attached.

3. Make sure that there is sufficient oil in the oil tank, then set the pump at the minimum or maximum stroke.

NOTE: *When checking maximum output, turn the pump pulley so that the ramp moves along the guide pin to the maximum position. Do not push the pulley straight into position because the plunger stroke may then be longer than when in actual operation.*

4. Turn the starter plate 200 revolutions in the direction of rotation indicated by the arrow on the plate. Measure the amount of oil in the graduated tube, and compare this figure with the standard value given in the chart at the end of this section.

5. To check at minimum pump stroke, reset the pulley to the minimum output position and repeat the operation.

Troubleshooting

Before proceeding, first check that the oil tank has a sufficient supply of oil.

1. In the event of piston seizure or overheating not caused by component failure or incorrect timing or carburetor settings, check the oil pump cable adjustment, the oil pump minimum stroke, the quality of oil being used (poor quality oil will cause this); check that the breather hole in the oil tank cap is open or that the oil tank breather tube (if fitted) is not blocked. Check for air in the lines by bleeding the pump. Check for air or oil leaks in the lines from the tank and to the engine.

Oil pump check valve cutaway view (Courtesy Yamaha Int. Corp.)

2. In the case of excessive smoking or oil consumption, check the oil pump cable adjustment. Check for leakage at banjo fittings, and cracked or broken oil lines. Make sure that the oil is of good quality.

3. Check that the oil pump is feeding oil to the engine by removing a banjo fitting, turning the throttle twist-grip fully open, and turning the starter plate by hand in the direction of rotation indicated by the arrow on the starter plate. Oil should dribble out of the banjo bolt hole. If it does not, either the pump is not getting any oil because of an empty tank, blocked feed line, or blocked tank breather, or the pump is defective. The latter would be an extremely rare occurrence.

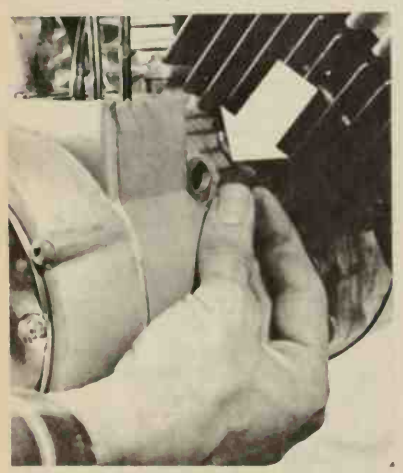
FUEL SYSTEMS

NOTE: *Refer to "Carburetors" in the General Information section for an explanation of carburetory theory, inspection, and troubleshooting.*

All Yamaha models covered in this manual are equipped with Mikuni carburetors, except for the RD125 and 200 which have Teikei units that are quite similar. Although similar in basic operation (all are concentric float bowl with cable-controlled throttle slides), working procedures vary slightly depending on the model of the carburetor.

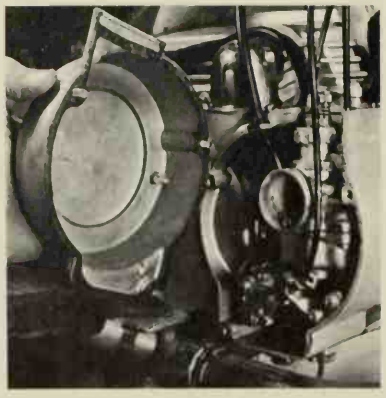
CARBURETOR SERVICE

Removal and Installation



ROTARY VALVE MODELS

The carburetor is located beneath the cover at the forward end of the right-side engine case.



1. Lift up the rubber carburetor cover. Remove the rubber plug on the front of the right engine case. Using an impact driver, if necessary, unscrew and remove the carburetor cover.

2. Unscrew the carburetor cap and pull out the throttle slide assembly.
3. Shut the fuel petcock off. Disconnect the fuel line from the carburetor.

4. With a screwdriver (slot head) loosen the carburetor mounting clamp which is accessible through the plug hole at the front of the carburetor case.

5. Pull the carburetor off its spigot.
6. Disconnect the overflow tube from the float bowl. Unscrew the starter plunger and pull it out of the carburetor body.
7. Drain the gasoline out of the carburetor before disassembly.
8. Installation is the reverse of the removal procedure. Be sure that all lines are firmly attached, and that the rubber grommets are properly seated.

PISTON PORT SINGLES

1. Shut off the fuel petcock. Disconnect the fuel line at the carburetor.
2. Loosen the air cleaner clamp screw at the carburetor.

3. Disconnect the overflow tube from the float bowl and the breather tube from the carburetor body. Slip the breather tube free of the clamp on the carburetor body.
4. Unscrew the carburetor cap and pull the throttle slide assembly out.
5. Loosen each of the carburetor bolts one turn, then unscrew and remove them, and remove the carburetor from the manifold.

6. Disconnect the oil feed line from the reed valve. Remove the securing screws, and remove the reed valve from the cylinder.

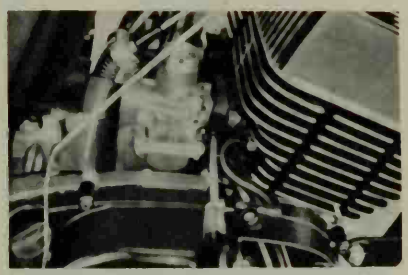
7. Drain the gas out of the carburetor before disassembly.
8. Installation is the reverse of the removal procedure. Check the condition of the reed valve and carburetor mounting flange gaskets, and replace them if damaged or if condition is doubtful. Tighten the carburetor mounting bolts evenly. Do not overtighten.



PISTON PORT TWINS

1. Loosen the air cleaner clamp screw at each carburetor and remove the rubber air cleaner hoses.
2. Shut off the fuel petcock and disconnect the fuel lines at the carburetors.
3. Unscrew the carburetor caps and pull out the throttle slide assembly for each carburetor.

4. Disconnect the starter lever linkage.
5. Disconnect the overflow tube from the float bowl for each carb. Disconnect the breather tube from each carburetor body. Slip the breather tubes free of the small clamp on each carburetor.
6. Loosen the clamp screw which secures each carburetor to the manifold, and pull them free together. On late models with the carburetors mounted in rubber spigots, a slot-and-pin arrangement is used to ensure correct vertical alignment of the carburetors. Therefore, be sure that the carbs are pulled straight out of the spigots, and are not twisted or turned to free them. When removing, note that in most cases the two carbs will still be connected by a balance tube, which may be disconnected after removal.

7. Drain the gasoline out of the float bowls after removal.
8. If removal of the reed valves is desired, disconnect the oil feed line at the banjo on each rubber spigot. Unbolt and remove the spigots and the reed valves.
9. Installation is the reverse of the removal procedure. Be certain that all carburetor lines are secured before operation.

Disassembly

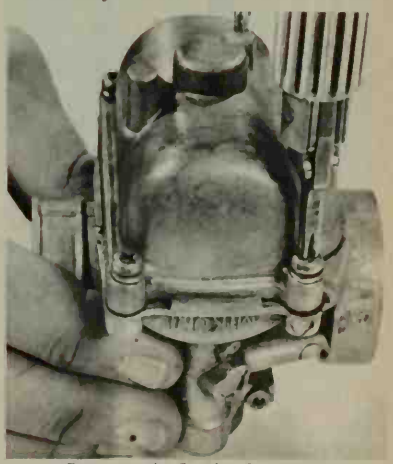
ALL MODELS

Disassembly procedures will vary slightly depending on the type of carburetor fitted.

IMPORTANT: *Note the location of all O-rings, washers, and gaskets when disassembling the carburetors. Refer to the exploded views if necessary.*

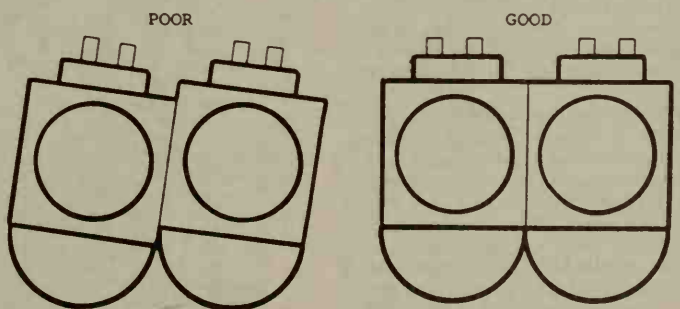
If disassembly of the throttle slide assembly is desired, refer to the procedures below. If a throttle stop rod is used to adjust the idle speed (rotary valve and some piston port models), see Step 1 and following. On all other models, begin with Step 2.

1. The idle speed adjuster screw on the carburetor cap has a small cotter pin at the top. Removing this pin will allow the throttle stop rod to be taken out of the bottom of the throttle slide.



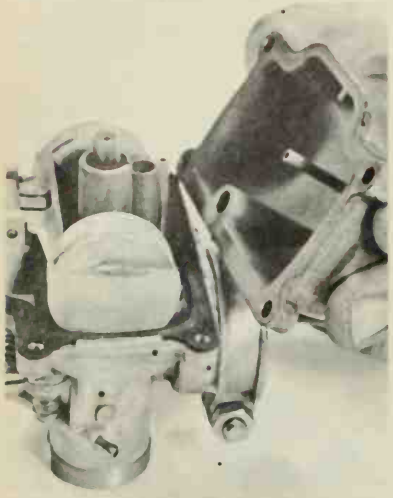
Detaching the throttle cable from the slide

2. Compress the throttle slide against the carburetor cap until the end of the cable protrudes from the bottom of the slide. Slip the cable end up along the slot in the slide until free, then remove the spring and the throttle slide.
3. Remove the spring seat or circlip from the inside of the slide, then turn it upside down to remove the needle and clip.



NOTE: *Do not remove the needle clip unless its position is to be changed.*

4. Turn the carburetor upside down, and remove the four float bowl screws. Remove the float bowl.



NOTE: *If the carburetor is old and has*

never been disassembled, the float bowl may be stuck to the gasket. Use a soft-faced (plastic) mallet to tap around the bowl until it is free. Restraint should be exercised while doing this.

Push out the float pivot pin

5. Push out the float pivot pin by hand or with a small punch, and remove the float assembly.

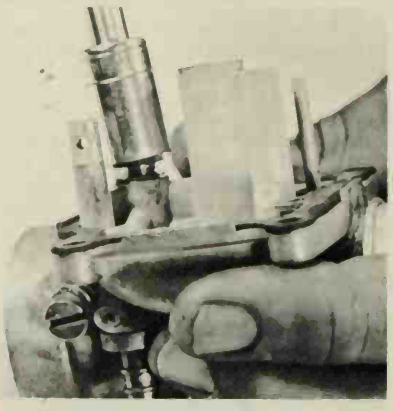
CAUTION: *Carefully note or mark the top side of the float assembly, since damage could occur if the attempt were made to install the floats incorrectly.*

6. Remove the float needle.

7. With a suitable socket, unscrew and remove the float needle seat.

8. Unscrew and remove the main jet.

CAUTION: *All fuel jets are very malleable and must be removed and installed with care to avoid damage.*



9. The needle jet is of two types, depending on model. If a hex-head is provided, simply unscrew and remove the

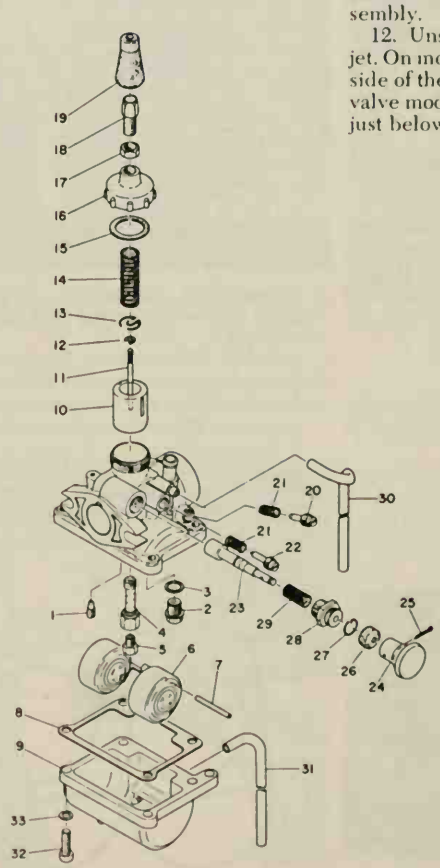
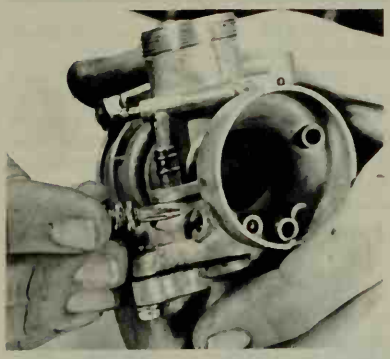
needle jet in the same manner as the main jet.



If this is not the case, the needle jet is recessed into a holder in the carburetor body. After removing the main jet, use a thin knife blade or something similar to remove the washer which is press-fitted at the bottom of the needle jet.

The needle jet is pressed into the carburetor body. To remove it, a wooden dowl should be used as a drift. Tap lightly at the bottom of the needle jet (the float bowl end) to force the jet into the carburetor bore.

10. Unscrew and remove the pilot jet.



11. If the starter plunger is still in place, unscrew the large nut on the carburetor body and remove the plunger assembly.

12. Unscrew and remove the pilot air jet. On most models, this is located on the side of the carburetor, but on some rotary valve models it is threaded into a passage just below the carb air intake.

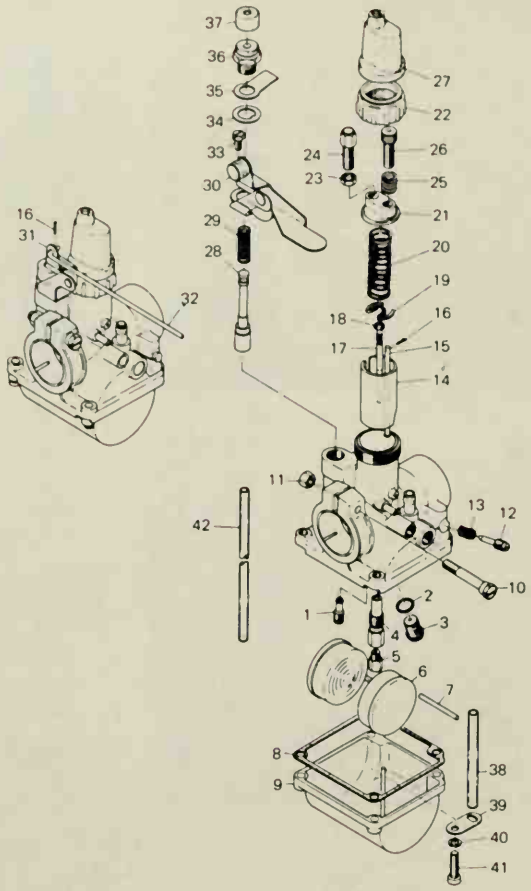
13. Unscrew and remove the throttle stop screw. Both the pilot air screw and throttle stop screws are held in adjustment by small springs. Be careful that these are not lost when the screws are removed.

Assembly

1. The following parts should be replaced each time the carburetor is disassembled:
   a. Manifold gasket and manifold O-ring (if fitted);
   b. Float bowl gasket;
   c. Float needle seat gasket;
   d. Throttle stop rod cotter pin (if fitted).
2. On rotary valve models, assemble the throttle slide assembly by first fitting the carburetor cap onto the throttle cable. Install the throttle stop rod through the bottom of the slide and attach it with the cotter pin to the top of the idle adjusting screw on the carburetor cap.
3. Install the needle, making sure that the needle clip is positioned in the same groove as it was found, unless tuning changes have been made. On twins, double check that both carburetors have the same needle setting.
4. Install the spring seat, return spring, and engage the throttle cable on the slide in the reverse of the disassembly procedure.
5. Install the pilot jet, being careful when screwing the jet in that it is properly seated.
6. Install the needle jet. If the needle jet is the pressed-in type, install it as it was removed with a wooden dowel drift, tapping it into its seat from the top of the carburetor. Install the needle jet washer.



NOTE: *If this type of needle jet is used, make sure that it is installed with the cutaway at the top of the needle jet facing the ENGINE side of the carburetor.*

7. Install the main jet; tighten it securely.
8. Install the fiber float needle seat gasket onto the needle seat, and screw the needle seat into the carburetor.
9. Place the float needle into the seat, and position the float assembly over the needle, ensuring that the correct side faces up. Slip the float pivot pin into the holder.
10. Adjust the float height.

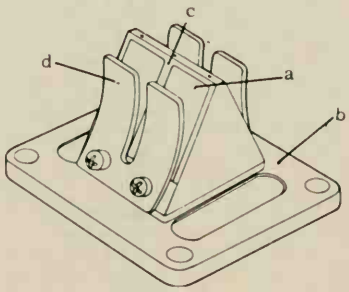
the float bowl, and install the four phillips head screws, tightening them gradually, and in an "X" pattern.

12. Refit the pilot air screw and spring. Screw in the pilot air screw until lightly seated, then back it off the prescribed number of turns given in the "Carburetor Specifications" chart at the end of this section. This is an approximate setting and may have to be readjusted when the engine is started. Install the throttle stop screw and spring.

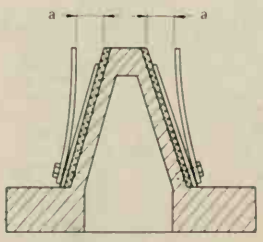
13. Install the starter plunger in the carburetor body and secure it.

14. Install the carburetor on the manifold and install the throttle slide assembly.



15. Refer to the "Maintenance" and "Tune-Up" sections if necessary to adjust pilot air and throttle stop screws, throttle cables, and throttle slide synchronization.

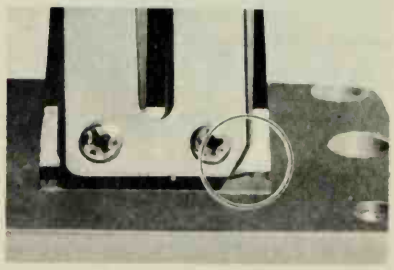
Reed Valve



The valve must not be handled excessively. Salt from the hands may damage the valve. Do not expose it to the sun and store it in a cool dry place if it is removed.

REMOVAL

1. Remove the carburetor.
2. Remove the four valve securing screws.
3. Gently remove the valve assembly from the cylinder. Do not pry the valve off.



Reed valve: a, valve; b, case; c, gasket; d, valve stopper (Courtesy Yamaha Int. Corp.)

Valve stopper clearance (a) should be about 9 mm (0.35 in.) (Courtesy Yamaha Int. Corp.)

INSPECTION

1. If the reeds and the stopper plate must be removed from the case use the cut in the lower corner of the reed and stopper plate as a guide to reassembly.
2. Reinstall the reeds and stopper plates in their original locations.
3. Check the rubber parts of valve for cracking and other signs of deterioration.
4. Inspect the reed petals for signs of fatigue cracks. The reeds should seat flush against their neoprene seats, or nearly so. Apply a suction to the carburetor side of the reed valve: the leakage should be very slight.

Note the cut edge of the reed as an aide to installation (Courtesy Yamaha Int. Corp.)

INSTALLATION

1. Apply Lock-Tite® or some similar thread bonder to the reed securing screws so that they will not fall into the engine during operation. Torque the screws to 0.6 in. lbs.
2. Install the valve carefully into the cylinder and tighten the valve securing bolts in a cross pattern.
3. Torque bolts to 5.1–7.2 ft lbs.

FUEL PETCOCK

1. The fuel petcock contains a wire mesh filter which should be removed and cleaned every 2,000 miles or every few months.
2. Unscrew the sediment bowl after shutting the fuel off.
3. Remove the filter from the petcock, and clean the bowl and the filter in a solvent.
4. Make sure that the petcock can fully shut off the gas. If leakage is noted when the petcock is in the "OFF" position, the petcock should be replaced.
5. Check the condition of the sediment bowl O-ring and replace it if damaged.
6. Replace the filter and sediment bowl. Do not overtighten the bowl. After installation, turn on the petcock and check for leaks.

If water has been getting into the carburetor from the gas tank, some or most of it can be removed by disconnecting the fuel line(s) at the carburetor(s) or petcock, placing a suitable container underneath to catch the gasoline, and turning the petcock to the "Reserve" position. Letting the gasoline run out for several seconds in this manner should remove any water present around the petcock line inside the gas tank.

7. Late models may have a fuel filter above the petcock which is accessible after removing the petcock from the tank.

ELECTRICAL SYSTEMS

COMPONENT TESTS

Use the following procedures in conjunction with the electrical specifications at the end of this section to determine faulty components.

DC Generator Voltage Output

1. Disconnect the generator wiring from the other components.
2. Connect a voltmeter to the armature terminal "A" (red) and ground field terminal "F" (black).

Checking generator output (Courtesy Yamaha Int. Corp.)

3. Run the engine up to about 2,500 rpm and check the voltmeter reading. If within reasonable bounds of the necessary output (6 or 12 volts), the generator is not likely to be the source of your problem. If the output is nil or minimal, isolate the cause by checking the carbon brushes and field winding insulation.

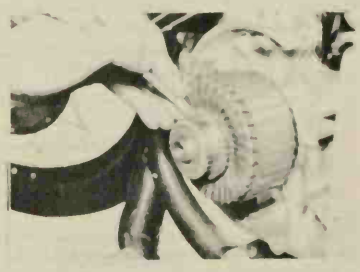
Checking positive brush insulation (Courtesy Yamaha Int. Corp.)

a. Check all brush wire connections.
b. Measure brush length and spring tension.
c. Make sure the positive carbon brush is properly insulated.

NOTE: *Disconnect the negative brush before checking for a positive brush short.*

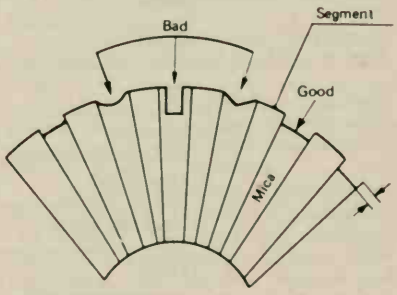
d. Check for any dirt, oil, etc. that may be shorting out part of the stator assembly.
e. Check for proper continuity between the armature and field windings (terminals "A" and "F").

NOTE: *Lift the carbon brushes off the commutator before checking field winding resistance.*



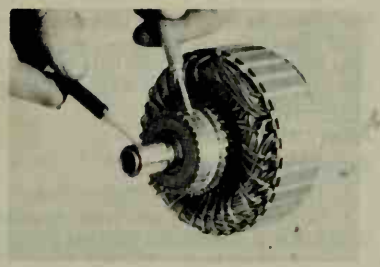
Checking field winding insulation (Courtesy Yamaha Int. Corp.)

f. Check field winding insulation with an ohmmeter set at the highest scale. Readings between the housing and terminal "A" and housing and terminal "F" should be infinite (3 megohms or more).
4. If the preceding tests didn't reveal the problem, perform the following checks on the armature:
a. Clean the commutator in a solvent. Make sure that the mica gaps are free from carbon dust which could short out the individual segments;



Checking for continuity between the armature and the field windings (Courtesy Yamaha Int. Corp.)

b. Check the mica undercut; refer to the specifications for each machine at the end of this section. If necessary, increase the mica undercut with a piece of hacksaw blade or thin screwdriver. Clean thoroughly afterwards;
c. If the commutator segments are corroded or scored, remove imperfections with sandpaper or a fine grade of emery cloth. Clean thoroughly with a solvent after this operation and check the undercut.



Increasing the mica undercut (Courtesy Yamaha Int. Corp.)

Mica undercut conditions (Courtesy Yamaha Int. Corp.)

d. Check for continuity between the commutator segments and armature *core*. Resistance should be infinite (no continuity). If continuity exists, the commutator is shorted against the core and the whole armature will have to be replaced.
e. Check for continuity between each of the individual commutator segments. There should be no resistance. If there is, the armature has an open circuit and must be replaced.

Checking for insulation between the commutator segments and the armature core (Courtesy Yamaha Int. Corp.)

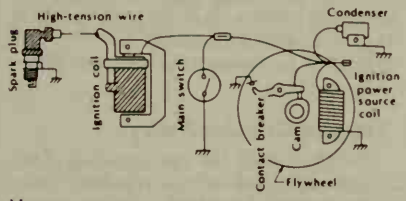
Starter Generator Brushes and Coil

1. Disconnect the negative starter brush and check the positive brush for insulation.

2. Disconnect the voltage regulator wiring and lift the positive brushes off the commutator. Make sure that there is continuity between terminals "A" and "M." No resistance indicates a broken starter winding.

3. Disconnect the heavy motor winding wire from the positive brush and make sure the windings are insulated.

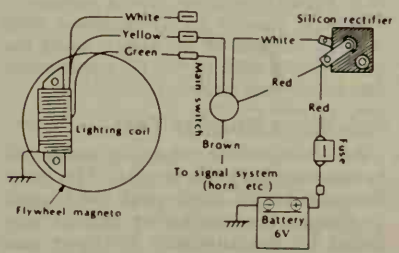
NOTE: *On early models, the fields and motor windings are internally connected. The readings on these machines must be exactly as specified.*



4. With the heavy motor winding wire still disconnected from the positive brush, make sure there is an open circuit between the "M" terminal and ground (at least 3 megohms).

Magneto Assembly

1. Make sure that all connections are tight.



2. Check all parts for any oil or water spots.

3. The flywheel magnets eventually weaken. If the points and condenser are good, but lighting and spark are weak, replace the flywheel or have the magnets recharged.

Magneto ignition circuit (Courtesy Yamaha Int. Corp.)

4. Check the primary ignition and lighting coils for any signs of having burnt out.

Magneto lighting circuit (Courtesy Yamaha Int. Corp.)

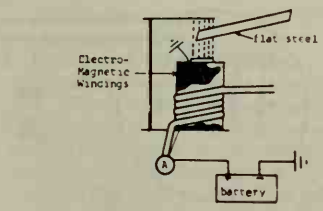
5. Make sure that the lighting coil wires all have continuity with each other.

6. Make sure that there is no continuity between the primary ignition coil leads and the coil core.

7. Check for continuity between the primary ignition coil lead and the coil mounting plate. Continuity must be present. If it is not, check for poor contact between the coil core and the plate or suspect a broken coil wire.

8. Check for continuity between the lighting coil lead and the coil mounting plate. If there is no continuity, check for poor contact between the coil core and the plate or a broken wire.

9. Check the ends of the coil cores and the inner surface of the magneto rotor to ensure that there has been no contact between the two as indicated by worn or scored marks. If contact has been made, check the crankshaft for play which would indicate a bad crankshaft bearing. Check that the coils are properly mounted on the plate and that the plate is secure. Any contact between the magneto rotor and the coil cores must be eliminated.



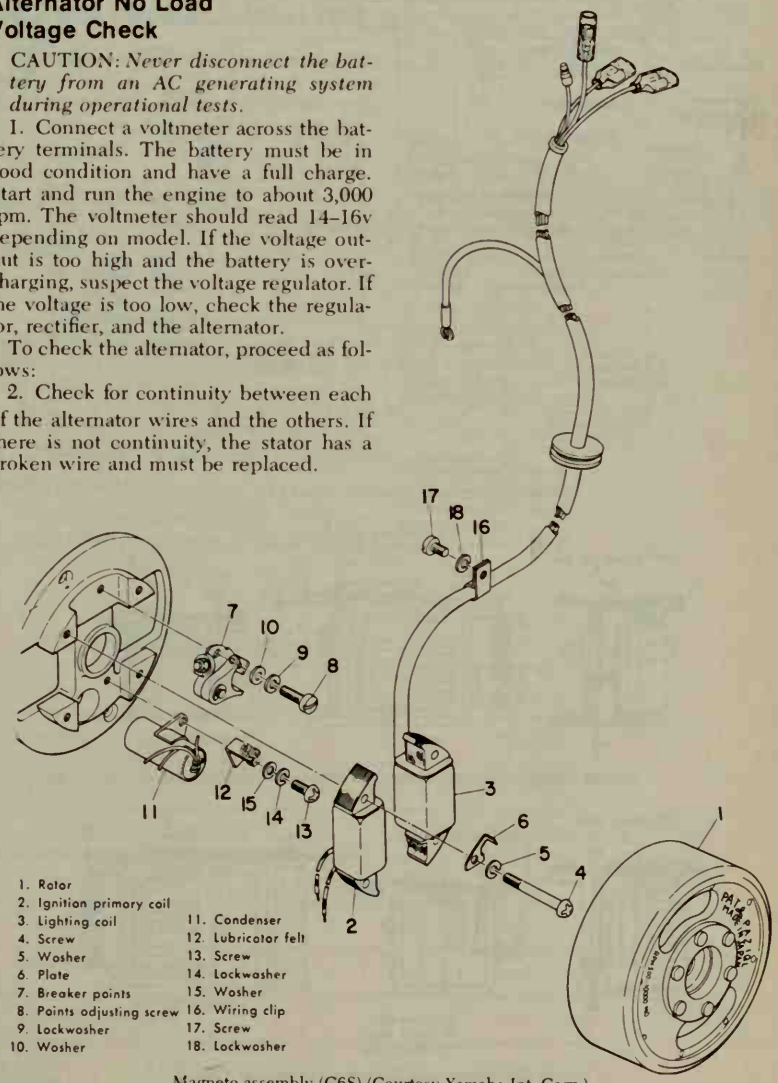
Alternator No Load Voltage Check

CAUTION: *Never disconnect the battery from an AC generating system during operational tests.*

1. Connect a voltmeter across the battery terminals. The battery must be in good condition and have a full charge. Start and run the engine to about 3,000 rpm. The voltmeter should read 14–16v depending on model. If the voltage output is too high and the battery is overcharging, suspect the voltage regulator. If the voltage is too low, check the regulator, rectifier, and the alternator.

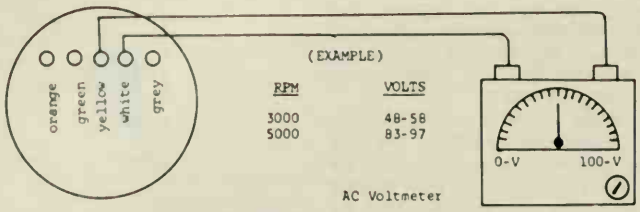
To check the alternator, proceed as follows:

2. Check for continuity between each of the alternator wires and the others. If there is not continuity, the stator has a broken wire and must be replaced.



Checking the voltage regulator relay coil (Courtesy Yamaha Int. Corp.)

3. Check for continuity between each stator lead and the stator housing. Each lead must be insulated (no continuity). If there is continuity, the stator wiring is internally shorted and must be replaced.



4. If the alternator is in the machine, check for continuity between the two (black and green) field coil leads. More than a few ohms resistance here indicates that the field coil is defective, one of the wire leads is broken, or one of the brushes is damaged.

5. After removing the alternator rotor, clean the slip rings thoroughly and check the resistance across them. If more than a

few ohms, the field coil is broken and the rotor must be replaced.

6. Check for continuity between each slip ring and the rotor core. If continuity exists, replace the rotor.

Alternator Average Amperage Check

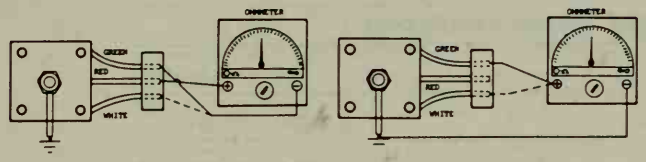
1. Disconnect the rectifier red wire.
2. Connect a DC ammeter positive lead to the red wire and connect the ammeter negative lead to the red wire connector.
3. Output at 3,000 rpm should be 2.8 ± 0.5A—day position, 6.7 ± 0.5A—night position; at 5,000 rpm, 3.2 ± 0.5A—day position and 7.1 ± 0.5A—night position.

Voltage Regulator Relay

NOTE: *If isolating a problem source, first check the generator as previously described, then check this relay.*

1. Check for any loose connections, broken solder, dirty points, etc.
2. Connect the correct voltage battery to the regulator coil as shown in the illustration, then insert a flat piece of steel into the electromagnetic field. If the steel is attracted by the field, the coil is OK.
3. Check the shunt resistors by connecting an ohmmeter positive lead to the "A" terminal and the negative lead to the "F" terminal. Manually operate the relay—each of the shunt positions should show a different resistance. If any of the positions indicate infinite resistance, one of the shunts is open.
4. Check the yoke, core, and point gap with specifications if given. Adjust if necessary.
5. Check the regulator no-load voltage by starting the engine, disconnecting the wire at regulator terminal "B," connecting the positive lead of a voltmeter to the terminal and the negative lead to ground. Increase engine speed to the specified rpm and check the reading against specifications. The voltage can be adjusted by bending the spring hook or turning the adjusting screw so that the point pressure is increased or decreased.

NOTE: *Increasing the pressure raises the voltage.*



Voltage Cut-Out Relay

NOTE: *Check the cut-out relay if the generator and voltage regulator relay are in good condition.*

1. Check the relay magnetic field as previously described.
2. Check and adjust yoke, core, and point gap as previously described.
3. Check the relay cut-out voltage in the same manner as the regulator relay no-load voltage. If necessary, bend the point spring hook so that the cut-out voltage meets specifications.

Full-Wave Recifier Test

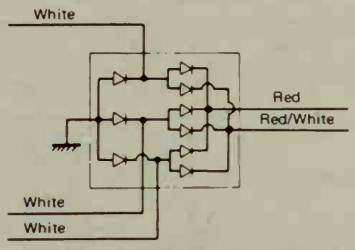
An ohmmeter or continuity tester can be used to check the rectifier. The rectifier consists of a diode pack and is used to change the alternating current produced by the alternator to direct current to charge the battery. A diode will pass current in only one direction if it is

Checking the rectifier (Courtesy Yamaha Int. Corp.)

operating properly, which is the key to the following tests.

3-WIRE RECTIFIER

This type is used on the smaller alternator machines.



1. Connect the positive tester lead to the red rectifier lead and the negative tester lead to each of the other leads in turn. Check for continuity. Now reverse the tester leads and repeat the test. For each pair of leads, there should be continuity in one direction only. If there was continuity in both directions, or in neither direction, the rectifier is defective and must be replaced.
2. Repeat the test, connecting one tester lead to ground and the other to each lead in turn. Replace the rectifier if any test does not conform to the one-way continuity rule.

5-WIRE RECTIFIER

This rectifier is fitted to larger machines such as the RD250/350/400.

1. Check for continuity between each of the white leads and the red rectifier lead. Then reverse the tester leads and repeat the test. In each case there must be continuity in one direction only. If any pair of leads show continuity in both, or in neither, directions, replace the rectifier.
2. Check for continuity between each white lead and the red/white lead. Reverse the tester leads and repeat the test. The findings must conform to the one-way continuity rule as in Step 1, or replace the rectifier.
3. Check for continuity between each lead and ground. In all cases there must be continuity in one direction only.

NOTE: *"No continuity" is indicated by a resistance of about 100 or more ohms, while "continuity" means 5–40 ohms resistance, if an ohmmeter is used for these tests.*

5-wire rectifier schematic (Courtesy Yamaha Int. Corp.)

Selenium Rectifier (2-Wire) Test

Connect an ohmmeter to the rectifier red and white wire leads, then reverse the meter leads. There should be continuity one way, but not the other.

See "NOTE," above.

Electric Starter Relay

If the starter motor does not function check the following:

1. Check for proper continuity in the starter relay core windings.
2. Check relay points for cleanliness.
3. When the points are closed, make sure there is continuity between the battery and motor windings.

NOTE: *The starter relay is located either on the frame, as a separate unit, or within the voltage regulator housing.*

Ignition Coil

NOTE: *Check the ignition coil if you are having spark plug firing problems and the battery, points, and condenser checked out OK.*

1. Check resistance between the positive and negative primary terminals.
2. Check continuity between one primary terminal and the high-tension secondary terminal. Compare the resistance with the specifications given.
3. Scrape some paint off the coil housing and check continuity between the primary winding and the coil housing. Resistance should read infinity.
4. Remove the plug cap and position the bare high-tension wire about ¼ in. from the cylinder head. Kick the engine over and check for a strong bright spark.

WHEELS AND BRAKES

Front Wheel Removal and Installation

Procedure will vary according to the type of forks and front brake fitted.

DRUM FRONT BRAKE

1. Support the front wheel several inches off the ground by placing a crate or the like beneath the motorcycle if necessary.
2. Disconnect the brake cable from the handlebar lever and then from the lever on the brake plate. Detach the cable from the adjuster if the adjuster is equipped

Detaching the speedometer cable from the brake plate

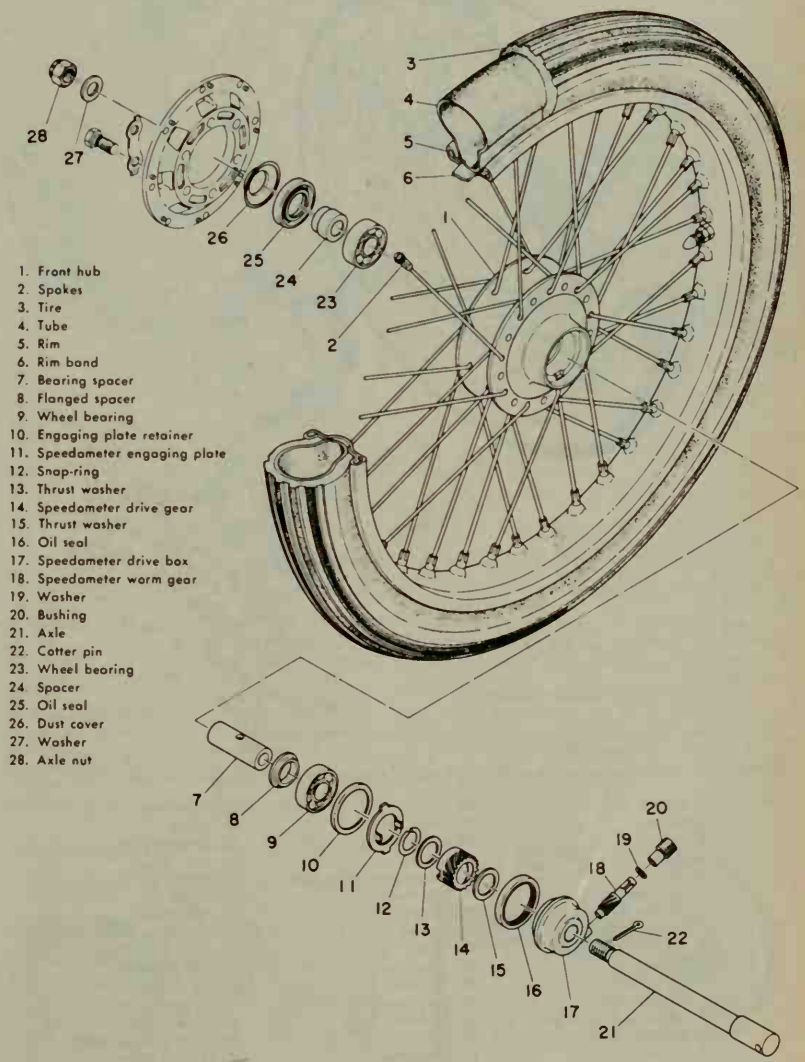
with a slot for this purpose. If not, unscrew the adjuster from the brake plate.

3. Remove the bolt or screw which secures the speedometer cable, and pull the cable out of the hub, ensuring that the rubber O-ring on the end of the cable is not damaged as this is done.
4. The front wheel is secured in a number of ways depending on model. On most lightweights, the axle is held only by the axle nut. On larger machines, a pinch-bolt is fitted to one fork slider. On late model 250–350 cc bikes, an axle cap (secured by two small nuts) is used.
5. Remove the axle nut cotter pin if fitted. Then remove the axle nut. Loosen the slider pinch-bolt (if so equipped), or remove the axle capnuts and the axle cap.

Loosening the slider pinch-bolt

6. Insert a phillips head screwdriver or similar tool into the axle and pull it out of the sliders.

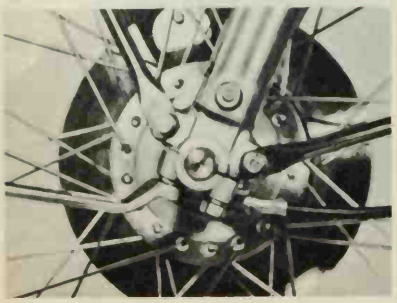
NOTE: *Twisting the axle while pulling it out or tapping the threaded end with a plastic mallet may be necessary to remove it. Lifting the wheel slightly to take the weight off the axle may also facilitate removal.*



7. Remove the wheel from the forks. On some lightweight models, an axle spacer on the left-side of the hub protrudes about an inch out of the oil seal. This spacer should be oiled lightly and then taken out of the seal using a twisting motion. If a dust cover is fitted to the hub, remove it now to avoid loss during handling of the wheel.

Removing the wheel dust cover

8. Refer to the wheel component service sections below if necessary. Installation is the reverse of the removal procedure. Ensure that the brake anchor cast into the brake plate is engaged with the slot on the fork slider. Tighten the axle nut securely; torque to 42–50 ft lbs. Using a new axle nut cotter pin is recommended.



On models using axle caps, note that the caps are machined unevenly, and must be installed with the gap towards the rear. Tighten the forwardmost cap nut first.

DISC BRAKE

1. Support the front wheel off the ground. Unscrew the speedometer cable from the drive mechanism.
2. Remove the axle nut cotter pin and remove the axle nut.
3. Loosen the two nuts on the axle cap.

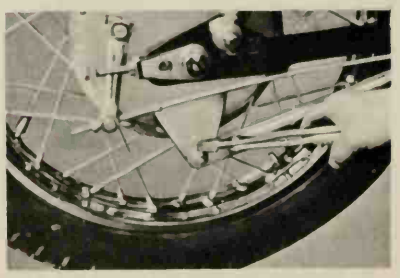
Install axle caps so that the gap is towards the rear. Tighten the front nut first (Courtesy Yamaha Int. Corp.)

Insert a phillips head screwdriver or similar tool into the hole in the axle and pull it out of the sliders.

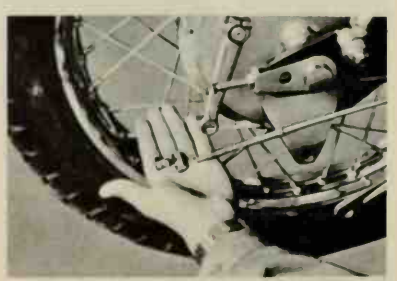
NOTE: *Using a twisting motion while pulling it out or tapping the threaded end with a plastic mallet may be necessary. Lifting the wheel slightly to take the weight off the axle may also facilitate removal.*



4. Remove the wheel from the forks.
5. Installation is the reverse of the removal procedure. Slip the brake disc into the caliper carefully. Tighten the axle cap nuts securely. Position the speedometer drive mechanism so that the speedometer cable is not subjected to any kinks or sudden bends. Tighten the axle nut to 42–50 ft lbs. (RD400:60–94 ft lbs.) Using a new axle nut cotter pin is recommended. Tighten axle cap nuts to 8–13 ft lbs. Note that the axle caps are machined unevenly and *must* be installed with the gap towards the rear. Tighten the forwardmost cap nut first.

Rear Wheel Removal and Installation

DRUM BRAKE



All models are fitted with a single-leading shoe rear brake which may be either rod or cable activated. The rear wheel can be removed without disturbing the sprocket and chain. On some models it is necessary to remove the muffler(s) to allow the axle to be taken out.

1. Remove the brake anchor cotter pin. Remove the anchor nut and detach the anchor from the brake plate.
2. Unscrew and remove the brake adjuster nut. Depress the brake pedal and disconnect the brake cable or rod from the brake plate lever. On cable-operated brakes, disconnect the cable from the brake lever and the cable adjuster from the holder on the brake plate. Remove the spring and place it along with the adjuster nut and clevis pin fitting in a safe place.

3. Loosen the chain adjuster locknut on each adjuster. Then back off the adjuster bolts to allow some free-play of the rear wheel.

4. Remove the muffler if necessary to allow removal of the axle. Remove the axle nut cotter pin, the axle nut, and tap the axle using a plastic mallet while pulling it out with a twisting motion.

5. After the axle is removed, remove the axle spacer on the right-side of the wheel, and the right-side chain adjuster. Pull off the brake plate and remove it from the machine. Pull the wheel as far as possible to the right, and remove it from the machine. On some models it may be necessary to lean the motorcycle slightly to the left to remove the wheel.

6. Installation is the reverse of the removal procedure. When fitting the wheel, ensure that the driving tabs on the sprocket assembly are engaged with the slots in the hub's rubber dampers. Adjust

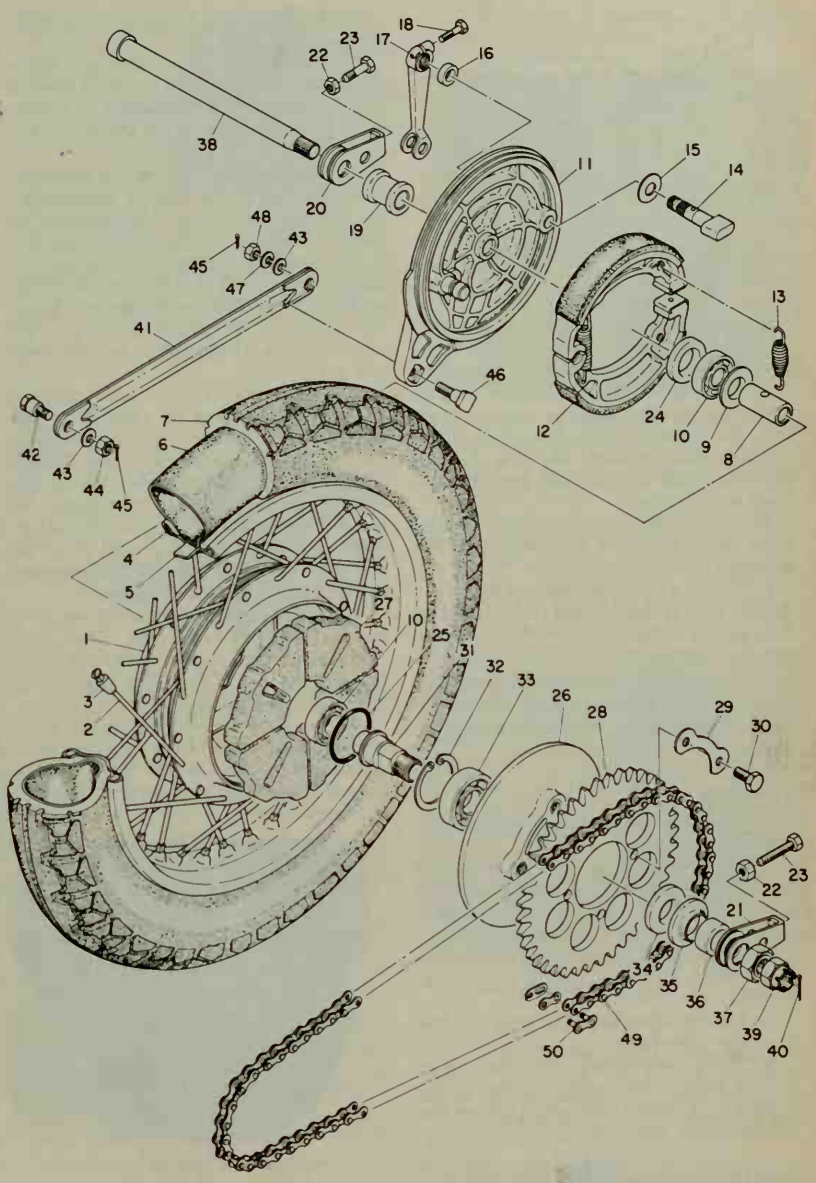
chain tension and the rear brake in that order. Tighten the axle nut securely; recommended torque is 42–50 ft lbs.

DISC BRAKE

1. With the motorcycle on the center stand, disconnect the drive chain. Remove the rear axle nut cotter pin and the axle nut.

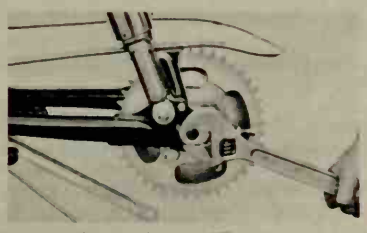
2. Pull out the axle and remove the rear wheel.



3. Grease the oil seal lips before installation. Installation is the reverse of removal.

SPROCKET ASSEMBLY, DRUM BRAKE

The rear sprocket assembly consists of the sprocket, sprocket hub, and sprocket hub bearing. Also included are the rubber hub dampers which will remain in the wheel when it is removed.



Removal and Disassembly

1. Disconnect the drive chain. Unscrew the large sprocket hub nut and remove the assembly from the swing arm.

Sprocket hub assembly (DS7) (Courtesy Yamaha Int. Corp.)

2. Bend down the tabs on the sprocket bolt locking plates. Unscrew the bolts, and remove the sprocket from the hub.

3. To remove the hub bearing, first remove the sprocket shaft by tapping it out from the sprocket side of the hub. Use a plastic mallet or wood block so that the sprocket shaft threads will not be damaged when struck.

4. Take off the sprocket shaft collar by hand, then the dust seal (fitted to late models).

5. Use an elbow-shaped tool to pry out the oil seal. If the oil seal is damaged on removal, as is likely, a new one must be fitted.

6. Remove the circlip on the inside of the hub. Drive the bearing out toward the sprocket side of the hub with a suitable drift or bearing driver.

Assembly

1. Assembly is the reverse of the disassembly procedure.

2. Lubricate the bearing as described in "Wheel Bearings," below. The bearing should be driven into place with a bearing driver or a suitable substitute.

3. Grease the lips of the oil seal before installation. The seal should be pressed into the hub with care.

4. Tap the sprocket shaft into the hub from the wheel side.

5. When connecting the chain masterlink, install the spring clip facing the direction of chain rotation. Tighten the sprocket hub nut securely.

SPROCKET (DISC BRAKE)

The sprocket is removed together with the wheel.

After bending down the lockwasher tabs, remove the sprocket bolts, circlip, plate washer, and sprocket.

Assembly is the reverse of disassembly. Note that the circlip has a bevelled inside edge and must be installed so that the high point of the bevel is towards the swing arm.

Be sure the sprocket/wheel mating surface is clean. Tighten bolts in a cross pattern to 43–54 ft lbs.

Drum Brake Service

All models use a single-leading shoe rear brake, while, with the exception of the disc brake models, a single or twin-leading shoe is used on the front brake. Yamahas use brakes in which the lining is bonded to the brake shoe. Lining and shoe, therefore, are purchased and replaced as a single unit.

1. Brakes can be inspected in place on the brake plate.

2. Inspect the shoes for wear. There should be at least 0.03 in. (0.77 mm) of lining material left (measured at the lining's thinnest point) or the shoes must be replaced.

3. An alternate method of checking brake wear is to use a large vernier caliper to measure the outer diameters of the shoes as shown in the illustration. For most twins the shoes must measure at least 175 mm (6.9 in.), or they should be replaced. For single-cylinder machines, the minimum acceptable reading is 105 mm (4.1 in.). This applies to both front and rear brakes.

4. Inspect the linings for scoring or grooves. These may be caused by particles of dirt which have entered the drum. If badly scored, the shoes should be replaced. If scoring of the shoes is evident, it would be wise to inspect the brake drum for the same type of damage.

Be sure that there is no oil or grease present on the linings. Oil-impregnated linings must be replaced.

5. If the linings are usable, rough up the surface with sandpaper. Then clean the linings thoroughly with alcohol or lacquer thinner. Clean the brake drum with the same solvent.

6. To disassemble the brake plate, simply grasp each shoe and fold them towards the center of the brake plate as shown. They may be installed using the same methed.

Installing shoes onto the brake plate

7. Remove the brake springs. Remove the brake lever pinch-bolt(s) and pull the lever(s) off the splined brake camshaft(s).

NOTE: *The plurals refer to twin-leading shoe brakes.*

8. Push the brake cam(s) out of the plate from the outside using hand pressure or by tapping with a plastic mallet. Note the presence of any shims on the cam(s) and be sure they are in place when the brake plate is reassembled. Remove the dust seal(s) from the brake plate.

9. Check that the brake lever pinch-bolts are not bent.

10. Inspect the splines on the brake cam(s). These should be in good condition. Check that the brake cams are not bent and that they can rotate freely in the brake plate passage. If it will not, use a fine grade of sandpaper on the camshaft and the surface of the brake plate passage.

11. Clean the cam(s) thoroughly in a solvent to remove any old grease, rust or corrosion. Use sandpaper or emery cloth to polish the cams. Clean off any residue; before reassembly, smear the cams with chassis grease.

12. Inspect the brake plate for cracks or fractures, and replace it if necessary.

13. On twin-leading shoe brakes, the brake plate linkage should be checked. The connecting rod is secured to each brake lever by a clevis pin and circlip. These pins can be removed after the circlips are taken off. They should be checked for wear, especially on high mileage machines, and replaced if necessary.

14. Check the condition of the brake springs, noting any twisted or fatigued hooks. Replace any broken, rusted, or old springs with new ones.

15. Clean all parts thoroughly with a suitable solvent, making a special effort to remove the dust and built-up dirt from the backing plate.

16. When reassembling the hub, note the following points:

a. Ensure that the brake cams are lubricated with chassis grease and that any shims which were on the cams are in place;

b. The use of new dust seals is recommended;

c. Lubricate the brake shoe pivot points with a little grease;

d. Install the shoes as on removal. Hook them together with the springs, and fold them down over the brake cam(s) and pivot(s).

BRAKE DRUMS

1. Upon disassembly of the hub, inspect the brake drum surface for condition. The drums must be clean and free from score marks or rust.

2. Rust can be removed from the drum surface with sandpaper. Polish the surface until it is shiny, then clean it thoroughly.

3. Alcohol or lacquer thinner can be used to remove dirt or deposits from the drum.

4. The drum should be checked for concentricity. An out-of-round condition is usually noticeable as an on-off-on feeling when the brake is applied while riding.

5. An out-of-round condition and most scoring can be removed by having the drum turned on a lathe.

Disc Brake Service (250/350/400 cc)

When handling disc brake fluid, observe the following cautions:

a. Brake fluid absorbs moisture very quickly, and then becomes useless. Therefore, never use fluid from an old or unsealed container;

b. Brake fluid will quickly damage paint. Place a protective cover on the gas tank;

c. Use only DOT #3 or DOT #4 brake fluid.

FLUSHING

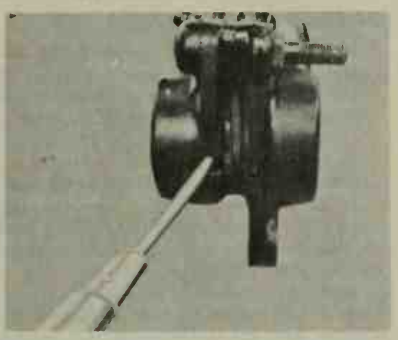
The brake system should be flushed out every 8,000 miles, or once a year.

1. Attach a length of vinyl tube, about 4 mm in diameter, to the bleed screw on the brake caliper, and put the other end into a small container.
2. Remove the master cylinder cap and the diaphragm. Loosen the bleed screw. Pull the brake lever slowly to the handgrip or pump the brake pedal (rear disc). Repeat until the master cylinder is almost empty.
3. Add new brake fluid to the master cylinder and continue squeezing and releasing the brake lever until the new fluid begins to come out of the vinyl tube. Bleed the system as outlined below.

BLEEDING

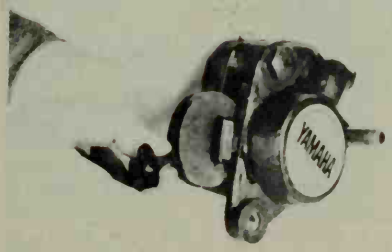
1. Needed for this operation are a torque wrench, a small cup, and a vinyl tube with an inside diameter of 4 mm.
2. Be sure that the reservoir is topped up. After checking the reservoir level, replace the diaphragm.
3. Connect the vinyl tube to the bleed screw on the caliper, making sure that it is a tight fit; then insert the other end of the tube into a small container with several inches of brake fluid in it. Be sure that the end of the tube is below the level of the fluid in the container.

Bleeding the disc brake (Courtesy Yamaha Int. Corp.)



4. Apply the brake lever *slowly* several times, then hold it ON.
5. While holding the brake lever on, loosen the bleed screw. The brake lever will be pulled toward the handgrip or brake pedal will be pushed down (rear disc). Close the bleed screw BEFORE the lever bottoms out on the handgrip.
6. Repeat the procedure until the fluid issuing from the lower end of the tube is completely free of air bubbles.

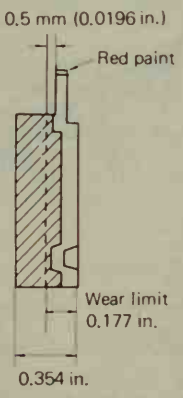
NOTE: *During the operation, keep a check on the reservoir fluid level, maintaining it near its normal position.*



7. Tighten the bleed screw to 4.5–6.7 ft lbs.
8. Top up the reservoir to the level line.

PAD REPLACEMENT

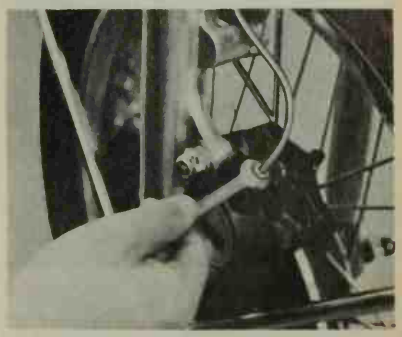
1. Pads must be removed to check for wear except on late models with wear indicators on the pads. Remove the front wheel and use a screwdriver to pry out each pad as shown. On newer models, the wear indicator obviates the need to pry out the pads.



Removing the brake pads from the caliper (Courtesy Yamaha Int. Corp.)

Removing brake pads on machines with wear indicators (Courtesy Yamaha Int. Corp.)

2. Minimum allowable pad thickness is shown in the accompanying illustration. This should be measured with an accurate instrument, and the pads replaced when thickness falls below 0.5 mm (0.0196 in.) or 4.5 mm (0.177 in.) depending on where the measurement is taken.



Brake pad wear limits (Courtesy Yamaha Int. Corp.)

3. Nominal thickness of new pads is 9.0 mm (0.354 in.).
4. Note that fitting new pads in place of a pair which were considerably worn will result in a rise in the reservoir fluid level. If it gets too high, drain off any excess fluid via the caliper bleed screw.
5. After installing new pads, avoid hard application of the brake for at least 50 miles.

CALIPER (FRONT)

Removal and Disassembly

NOTE: *A compressed air supply will be necessary to remove the pistons from the caliper.*

Disconnecting the brake line from the caliper (Courtesy Yamaha Int. Corp.)

1. Use a length of tape to hold the brake lever in the "on" position.
2. Disconnect the brake line from the caliper. Cover the end of the line with a small plastic bag, which will keep out dirt or foreign matter.
3. Unbolt the caliper, lift it up, and remove it from the slider.

Removing the caliper bolts (Courtesy Yamaha Int. Corp.)

4. Remove the pads. Remove the bridge bolts and the hex-head caliper bolts, and separate the caliper halves.
5. Remove the seal from the fluid passage.

Removing the fluid passage seal (Courtesy Yamaha Int. Corp.)

6. Apply compressed air to the fluid passage in each caliper half to force out the pistons.

NOTE: *This is the only recommended method of removing the pistons.*

7. Remove the piston seal and the dust seal from each caliper half.

Removing the dust seal from the caliper (Courtesy Yamaha Int. Corp.)

Inspection

NOTE: *Caliper components should be kept free of any solvent. Parts should be cleaned only in brake fluid.*

1. Check the pads for scoring and replace them if scored. Check pad thickness as directed above.
2. Inspect the pistons for scoring along the sides or for other signs of wear. Replace as necessary.
3. Replace any damaged seal in the unit. All seals should be replaced every two years regardless of appearance.
4. The two bridge bolts *must* be replaced each time they are removed.

Assembly and Installation

1. Clean all parts in new brake fluid.
2. Install the dust seal and piston seal in the caliper halves.
3. Coat the caliper cylinder walls and the pistons with new brake fluid, and then carefully insert each piston into its own caliper half.

Be sure that the piston goes in smoothly.

4. Install the caliper seals.
5. Fit the two caliper halves together, and replace the two hex-head bolts and tighten them to 13–19 ft lbs.
6. Install new bridge bolts and tighten them to 56–71 ft lbs.
7. Install the pads. It will be necessary to push the pistons back by hand when installing the pads.
8. Replace the caliper on the fork slider, tightening the nuts to 30–37.2 ft lbs.
9. Refit the brake line to the caliper and tighten it to 10–13.4 ft lbs.

CALIPER (REAR)

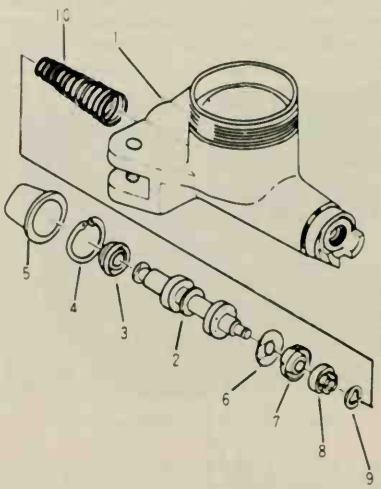
Removal

1. Disconnect the brake line at the caliper. Wrap the banjo with a cloth or plastic bag to prevent fluid loss.
2. Remove the caliper mounting bolts and take off the caliper.
3. For service, refer to "Caliper (Front)". The units are virtually identical.

Installation

1. Tighten mounting bolts to 22–35 ft lbs.
2. Tighten brake line-to-caliper bolt to 22–35 ft lbs.

BRAKE DISC



1. Check the disc for run-out by securing a dial gauge to the fork slider. If run-out is 0.15 mm or more, remove the disc and check for warpage. If the disc is not warped, suspect the wheel bearings.
2. Measure the thickness of the disc. Minimum allowable thickness is 6.5 mm.
3. To remove the disc, remove the front wheel, bend down the locking tabs on the disc securing bolts, and remove the bolts.
4. When installing the disc, care should be taken to tighten the bolts evenly and gradually until the proper torque (250/350: 5.7–7.2 ft lbs; 400: 12.3–16.0 ft lbs) is reached. Ensure that the locking tabs are bent up against the flats on the disc bolts.

MASTER CYLINDER (FRONT)

Removal and Disassembly

CAUTION: *A special guide is needed to install the piston cylinder cup once it has been removed. Do not disassemble the piston unless this guide is available.*

1. Remove the brake light switch at the master cylinder, and remove the brake lever, watching for the return spring.

2. Disconnect the brake hose at the master cylinder.
3. Remove the master cylinder mounting bolts, and remove the assembly from the handlebar.
4. Remove the reservoir cap, take out the diaphragm, and drain off the fluid.
5. Remove the boot.
6. Remove the snap-ring with a pair of snap-ring pliers.
7. Take out the piston. Take out the spring behind the piston.
8. Remove the circlip from the piston assembly, and take off the cylinder cup retainer, then the cylinder cup.

Inspection

1. Wash all parts in new brake fluid only.

2. Check the master cylinder port for clogging due to foreign matter.
3. Be sure that the reservoir is clean.
4. Check the walls of the master cylinder for grooves or score marks.
5. Check the outlet end for dents or other damage.

In the event of any permanent damage, replace the master cylinder body.

Removing the piston circlip (Courtesy Yamaha Int. Corp.)

6. Check the piston for wear or rust and replace as necessary.

7. Check the condition of the cylinder cup noting any evidence of groove wear on the contact surface. Replace if any is evident.

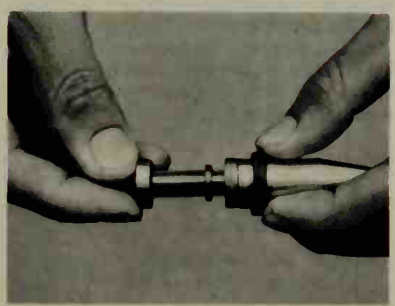
8. Check all rubber parts for wear damage, or swelling. Replace as necessary. Note that all rubber parts should be replaced every two years regardless of appearance.

9. Check the reservoir diaphragm for cracks or damage to the edges and the accordion pleats. Check the diaphragm and the boot for swelling.

These components should be replaced if damaged or worn, and replaced every two years regardless of appearance.

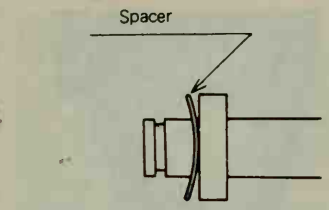
10. The master cylinder spring minimum length is 60.4 mm. Replace it if it is shorter than this or if it shows signs of damage.

11. Check the brake hose and line for cracks or seepage. The brake hose should be replaced every four years regardless of condition.



12. When installing the hose and line, note that they should not contact the forks or frame at any point except where attachment clips are fitted.

Assembly and Installation



1. Dip the cylinder cup in new brake fluid, and, using the special guide, install the cup on the piston.

2. Install the spacer. Note the correct position. Fit the cup retainer and circlip.

3. Fit the conical spring into the master cylinder body. Then carefully insert the piston assembly into the cylinder. Do not force the piston in.

4. Install the snap-ring. Refit the boot, being sure that it is correctly installed in the cylinder and piston grooves.

Fitting the spring (Courtesy Yamaha Int. Corp.)

5. Install the master cylinder on the handlebar. Adjust the clearance between the piston and pushrod. Make sure that the adjusting screw locknut is firmly tightened.

6. Reconnect the brake hose. Put about 30 cc of brake fluid into the reservoir.

7. Bleed the system as previously described.

MASTER CYLINDER (REAR)

Removal

1. Remove the brake light switch wire.

2. Disconnect the brake line at the master cylinder.

3. Remove the two securing bolts and take off the master cylinder.

4. Refer to "Master Cylinder (Front)" for service procedures.

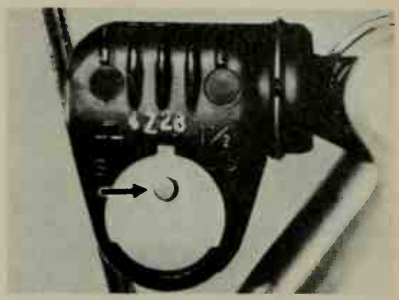
Installation

1. Tighten securing bolts to 22–35 ft lbs.

Disc Brake Service (RD200C)

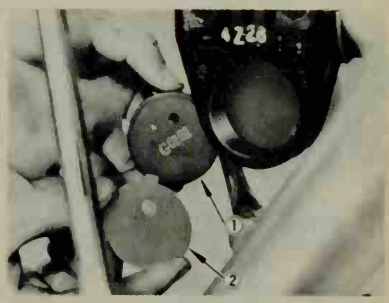
The RD200C is fitted with a front disc brake slightly different in construction from that used on 250/350/400cc machines.

Observe precautions outlined at the beginning of the 250/350/400 disc brake section.



Flushing and Bleeding procedures are the same as outlined for the larger machines.

Use DOT #3 or #4 brake fluid.



PAD REPLACEMENT

1. Remove the front wheel.

2. Remove the phillips screw from the wheel side of the caliper, taking out the metal pad support and the outer pad. Remove the inner pad.

Pads removed (RD200C) (Courtesy Yamaha Int. Corp.)

3. Check pad thickness. Standard thickness is 15 mm (0.6 in.) for the inner pad and 12 mm (0.48 in.) for the outer.

Replacement limit is 11 mm (0.44 in.) inner, and 7.5 mm (0.3 in.) outer.

4. Smear the sides of the pads with a light coat of silicon grease before installation.

CALIPER

The caliper is a one-piece type.

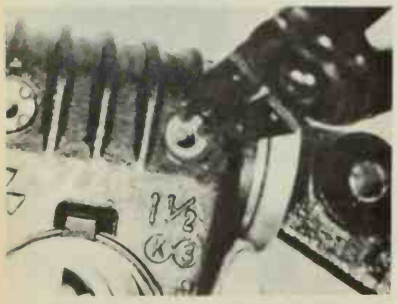
Removal and Disassembly

1. Remove the front wheel. Remove the brake pads.

2. Disconnect the brake line at the caliper, blocking the end of the line to prevent fluid loss.

NOTE: *Apply the brake lever, keeping it on with tape or the like to prevent fluid leakage from the master cylinder.*

3. Unbolt and remove the caliper.



4. Remove the rubber boot retaining ring from the caliper. Remove the boot.

5. Remove the blind plugs from the wheel side of the caliper. Remove the circlips revealed by plug removal.

6. Screw a 5 mm screw into the pins and pull them out. Remove the caliper bracket.

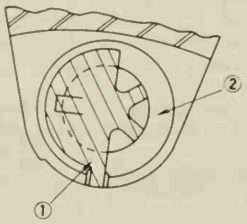
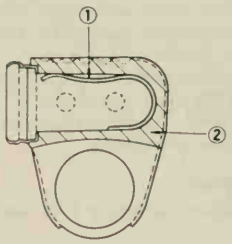
7. Remove the anti-rattle spring. Remove the anti-squeak shim.



8. Apply compressed air at brake line fitting on the caliper to force out the piston. Remove the piston dust seal and fluid seal.

Inspection



Refer to "Inspection" for the 250/350/400 caliper, above.

Assembly and Installation

1. Assembly is the reverse of disassembly. Coat caliper walls, piston, and seals with clean brake fluid.

2. Use silicon grease on both sides of the anti-squeak shim. Install the anti-rattle spring as illustrated. Lubricate rubber/metal contact areas and caliper pins with silicon grease.

3. Tighten caliper mounting bolts to 16–23 ft lbs.

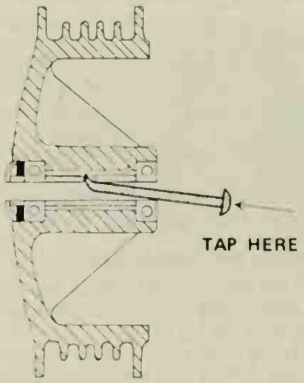
MASTER CYLINDER

Refer to "Master Cylinder (Front)" for 250/350/400 models, above. Procedures are similar.

Wheel Bearings

Removal of the wheel bearings necessitates removing the hub oil seals. These must be replaced with new ones upon reassembly. In addition, a drift with a hooked end should be used to remove the bearings. Refer to the illustration. Clean the outside of the hub before removal.

DISASSEMBLY

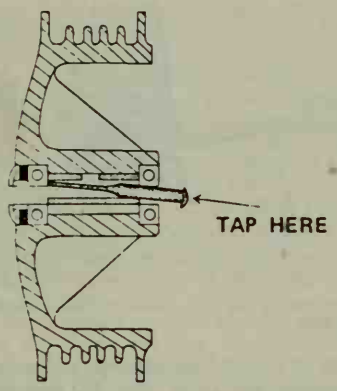


1. Remove the wheel and take out the brake plate (drum brakes). On disc brake wheels, remove the speedometer drive mechanism.

2. Remove any dust covers, dust seals, or axle spacers fitted to either side of the hub.

3. Pry out the oil seals on either side of the hub using a small screwdriver, or, preferably, an elbow-shaped tool.

Prying out a wheel bearing oil seal



Removing a wheel bearing from the hub with a hooked tool (Courtesy Yamaha Int. Corp.)

4. Using the bearing removal tool, or a suitable substitute, engage the hole drilled into the bearing spacer. Striking the removal tool with a hammer will drive out one wheel bearing. Alternatively, a straight punch may be used to remove the bearing. Move the spacer to one side as shown in the illustration and tap it out.

5. Take out the bearing spacer and spacer flange. Drive out the other bearing with a suitable drift.

NOTE: *On some models, especially high mileage machines, the hub should be heated gently with a propane torch in the vicinity of the bearing bosses to facilitate removal.*

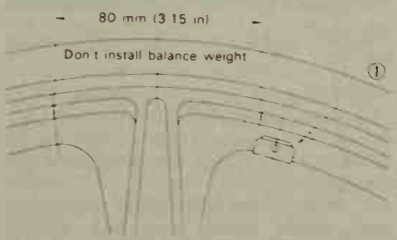
Alternate method of removing the wheel bearings (Courtesy Yamaha Int. Corp.)

ASSEMBLY

1. Obtain a good grade of wheel bearing grease to lubricate the wheel bearings.

2. Pack the grease in the bearing. A common method of doing this is to place a goodly amount of the grease in the palm of one hand. Taking the clean, dry, bearing, press one section of it into the grease. Turn the bearing until the grease has been deposited around the entire circumference. The packing process is complete when the grease begins to come out of the upper side of the bearing. Place an amount of grease in the hub as well.

3. Heat either side of the wheel hub with a propane torch as on removal of the bearings. Place one of the bearings in the hub, and make sure that it is seated. Drive in the bearing using a bearing driver, or a block of hard wood large enough to cover the whole bearing. Tap lightly around the outer bearing race before driving it in to be sure that the bearing is started properly in the hub.



NOTE: *The bearings must be driven straight in; do not attempt to force in a cocked bearing.*

4. Fit the spacer flange and spacer, and install the other wheel bearing.

5. Press in new oil seals on both sides of the hub.

Wheel Balancing (RD400)

Balancing of the alloy wheels on the RD400C is performed in the same manner as for conventional spoked wheels (See "Chassis" in the General Information section), except that balance weights must not be installed closer than 40 mm to the center line of the spokes.

FRONT FORKS

Two basic types of forks are used: one for lightweights (200 cc and under) and most older bikes, and another type for the larger machines, including the RD200.

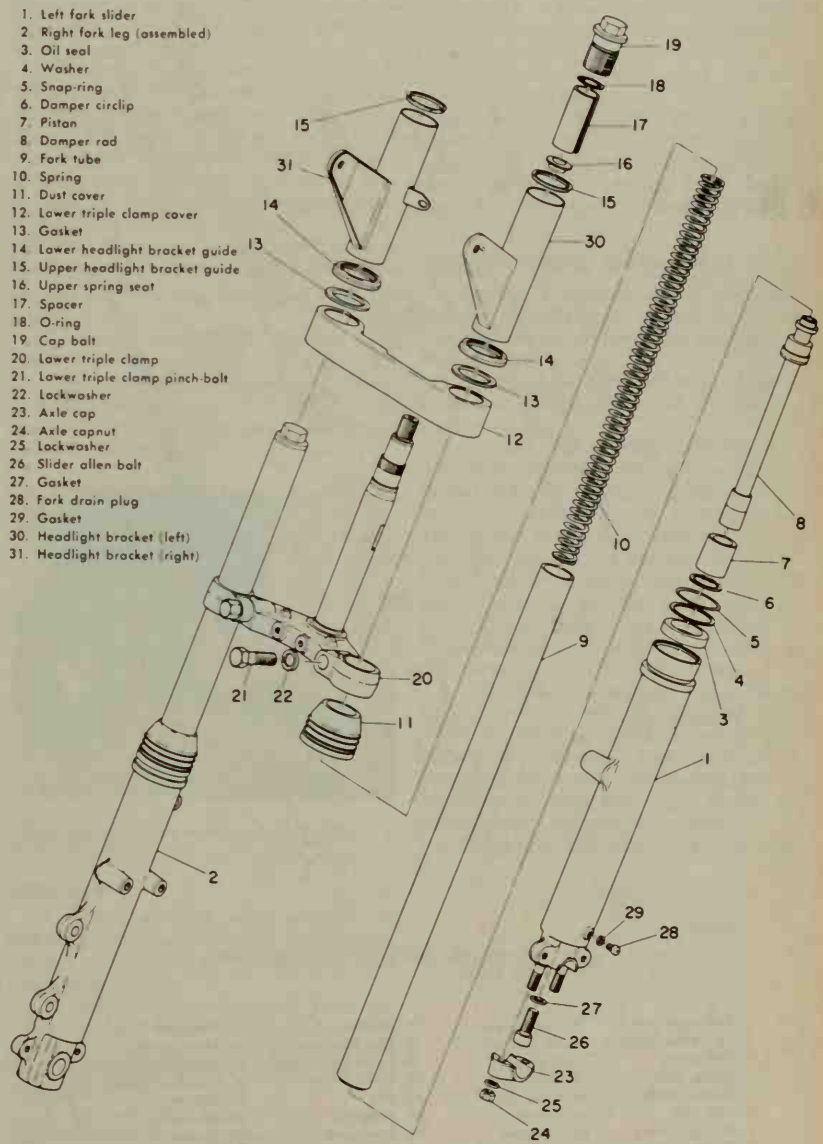
The chief distinctions are the use of external fork springs on most of the light-weight forks with the exception of machines such as the RD125 and 200B, and the method of securing the slider to the fork leg. Larger machines use an allen bolt in the bottom of the slider which threads into the damper, while others have a circular nut fitted to the top of the slider. The slider oil seal is pressed into the top of the slider nut, while on newer models an O-ring is also fitted to the lower end of the nut.

The "heavyweight" fork type is used on such machines as the RD200C, DS7, R5/B/C, RD250-350A/B, and RD400.

On all forks, the fork slider oil seals must be replaced each time the slider is removed from the fork inner tube.

Removal and Disassembly

HEAVYWEIGHT TYPE



1. Support the front end of the machine well off the ground. Remove the front wheel and the front fender.

2. On disc brake models, unbolt and remove the brake caliper from the fork slider.

3. Loosen the handlebar bolts just enough to allow the bars to be pulled back towards the rider to give access to the fork cap bolts.

4. Each fork leg assembly is removed separately from the triple clamps. Loosen the fork cap bolt on one of the fork legs. As the bolt is removed, press down on it with your hand to prevent it from popping off due to spring pressure. Remove the cap bolt, the washer (if fitted), and

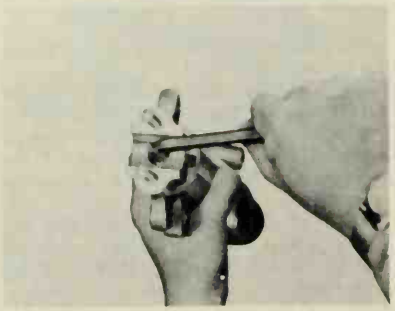
spring spacer. Take out the upper spring seat and the fork spring.

5. Loosen the upper and lower triple clamp pinch-bolts for the partially disassembled fork leg.

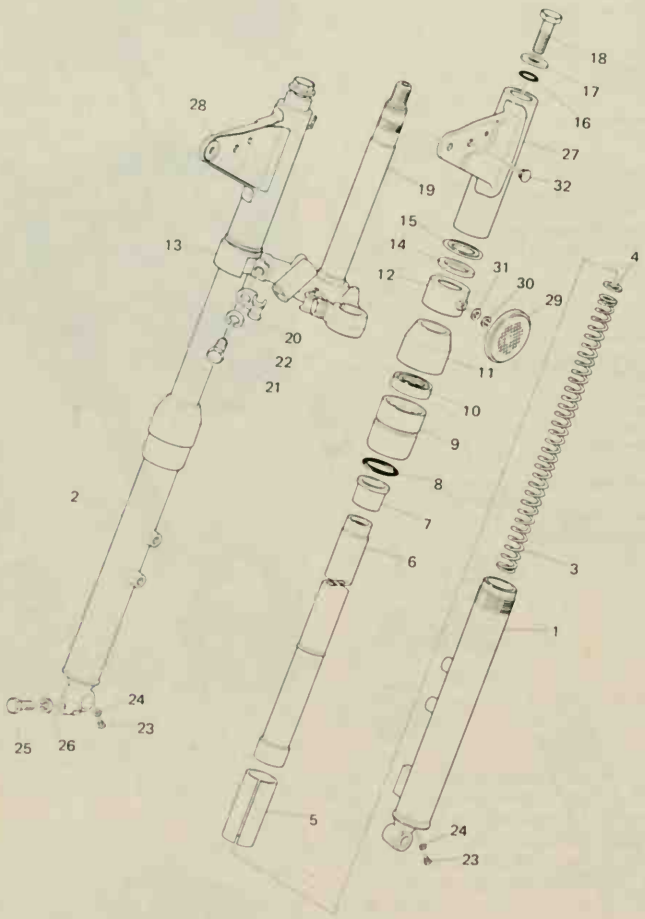


6. Grasp the fork slider for that fork leg and pull it sharply downward to free the fork tube from the triple clamps. Remove the dust seal cover (DS7, R5) and the dust seal, by prying them off the top of the slider.

7. Turn the fork leg upside down to drain off the fork oil.

8. Remove the axle cap from the bottom of the slider if fitted. The fork slider is secured to the fork tube by an allen bolt in the very bottom of the slider. Pull the slider and fork tube as far apart as possible, extending the assembly to its full length. Remove the slider allen bolt. An impact driver may be necessary.

9. Pull the slider free of the fork tube.



10. The slider oil seal will remain in place in the slider. To remove it, remove the snap-ring, the washer, and pry the seal out of the slider with a small screwdriver or hooked tool.

11. Remove the circlip from the bottom of the damper, take off the piston, and remove the damper from the top of the fork tube.

12. Repeat the procedure with the other fork leg.

Removing the fork slider oil seal (Courtesy Yamaha Int. Corp.)

13. If only the fork slider oil seals need attention, the slider may be removed while leaving the fork tube assembly in place as follows:

a. Drain the fork oil;

b. Remove the front wheel, fender, and the caliper on disc brake models;

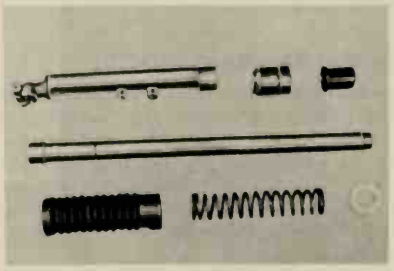
c. Pry up the dust seal cover (if fitted), and the rubber dust cover from the top of the fork slider;

d. Remove the axle cap if it is fitted;

e. Pry out the oil seal snap-ring; remove the washer;

f. Remove the allen screw from the bottom of the fork slider and remove the slider from the fork tube;

g. Assembly will be made easier if the fork cap bolts are removed to relieve fork spring tension.



EXTERNAL FORK SPRING AND LIGHTWEIGHT TYPE

With minor constructional variations, this type of fork is used on lightweight machines and on early 200–350 cc models such as the R3, DS6, YDS-series, CS-series, RD125 and 200B.

The fork slider is secured to the fork inner tube by a large circular nut. The slider oil seal is also located in this nut. Some models have an O-ring in the bottom of the nut as well.

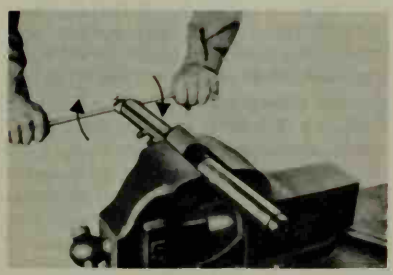
1. Support the front wheel well off the ground. Remove the front wheel and fender.

2. Remove the fork cap filler bolt, washer, and O-ring (if fitted).

External spring fork components (Courtesy Yamaha Int. Corp.)

3. Loosen the upper and lower triple clamp pinch-bolts for one of the fork legs. Grasp the slider and pull sharply downward to free the fork leg from the triple clamps.

4. Remove the fork boot or slider dust seal, upper spring seat, fork spring, spring guide (if fitted), and lower spring seat from the fork tube, or remove the



inner fork spring from the fork tube.

5. Drain the oil out of the top of the fork tube.

6. To disassemble the fork leg, a device must be used to clamp the slider nut so that it can be turned. In many cases, a large heater hose clamp will work. Tighten the heater hose clamp around the slider nut; a piece of old inner tube should be used beneath the clamp to protect the chrome. Clamp the slider in a vise, preferably by the axle lug. Unscrew the slider nut and remove the slider from the fork tube.

An alternative method requires clamping the slider nut in a vise (protected with rubber padding or the like), and unscrewing the slider from it as shown in the illustration.

A strap wrench on the slider nut, if one is available, is the easiest method.

Removing the fork slider circular nut (Courtesy Yamaha Int. Corp.)

7. Remove the slider nut with the oil seal by the top of the fork tube, followed by the sliding bushing. The oil seal, which must be replaced, can be pried out of the circular nut with a small screwdriver or hooked tool.

8. Repeat the procedure with the other fork leg.

Assembly and Installation

ALL MODELS

1. Assembly is the reverse of the disassembly procedure. Note the following points.

2. All O-rings, oil seals, and felt washers must be replaced.

3. Slider oil seals should be pressed directly into the slider or circular nut (depending on fork type) with a suitable drift which will cover the whole seal. This will minimize chances of distorting the seal when installing it and will allow it to be fully seated. On some models, the old seals can be used to drive in the new.

4. Grease the lips of the oil seals before installing on the fork tubes. After installing the slider on the fork tube, check that it can move smoothly up and down.

5. When installing the tubes in the triple clamps, ensure that the top of the tubes are flush with the top surface of the upper triple clamp. Tighten the upper and lower triple clamp pinch-bolts securely.

6. Refill each fork leg with the proper viscosity and quantity of oil.

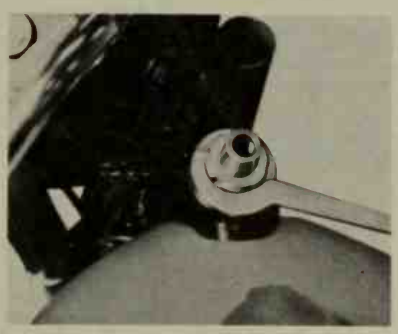
STEERING STEM

Bearing Adjustment

1. The steering stem bearings are uncaged ¼ in. balls. They are adjusted by means of a ring nut beneath the upper triple clamp.

2. To check bearing adjustment, support the front wheel off the ground. Grasp the tip of the front fender, place your other hand beneath the lower triple clamp at the frame lug.

3. Attempt to move the forks by pulling up on the front fender. If play or movement can be felt at the lower triple clamp, the bearings are too loosely adjusted or worn.



4. Turn the forks slowly from lock-to-lock. Movement should be smooth, silent, and effortless. If any binding or uneven movement is felt, the balls and races are either too tightly adjusted or are worn. If the steering feels uniformly stiff, the bearings are too tightly adjusted. If any noise is noted, the bearings are damaged, or some are missing.

5. With the front wheel off the ground, release the front forks from a few degrees off the centered position. The forks should fall freely to either side of their own weight. If they will not, the bearings are too tightly adjusted, the steering stem is bent, the races are extremely worn, or some of the balls are missing.

6. Bearings can be adjusted with a hammer and blunt punch or pin wrench on the adjuster nut after removing the upper triple clamp.

7. Tighten or loosen the adjuster nut a little at a time until the steering stem adjustment conforms to that outlined above.

8. If proper adjustment is not possible, the bearings and races will probably need to be replaced.

Adjusting the steering stem bearings (Courtesy Yamaha Int. Corp.)

Removal

1. Disconnect the cables, remove the electrical switches from the handlebars; unbolt and remove the handlebars from the motorcycle.

2. Unbolt the instruments from the upper triple clamp and lay them carefully aside. Unbolt the headlight from the brackets and allow it to hang by the wiring harness.

3. Remove the front wheel, fender, brake caliper (if disc brake), and remove both fork legs from the triple clamps.

4. If a friction steering damper is fitted, remove the damper plate cotter pin beneath the lower triple clamp. Unscrew the damper rod and remove it. Remove the damper plate bolt and lockwasher and the damper plates.

5. Loosen the upper triple clamp pinch-bolt behind the large triple clamp nut. Then remove the nut, the spring on models with a steering damper, and the large washer.

6. The upper triple clamp can now be removed. Tap upwards on the underside of the triple clamp with a plastic mallet until it is free.

7. Remove the headlight brackets. Since the steering head ball bearings are uncaged, it is likely that some will drop out of the races when the steering stem is lowered. Therefore, if the bearings are going to be reused, cover the ground beneath the assembly with a drop cloth.

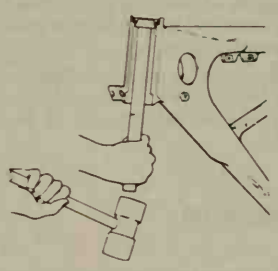
8. With a hammer and punch, loosen the bearing adjuster nut until it can be turned by hand. Support the lower triple clamp with one hand while unscrewing the adjuster nut until it can be removed from the steering stem.

9. Remove the dust cover and the upper steering stem race.

10. Carefully lower the steering stem out of the frame lug. The top bearing balls should remain in the steering lug race. The bottom bearing balls should remain in the lower steering stem race.

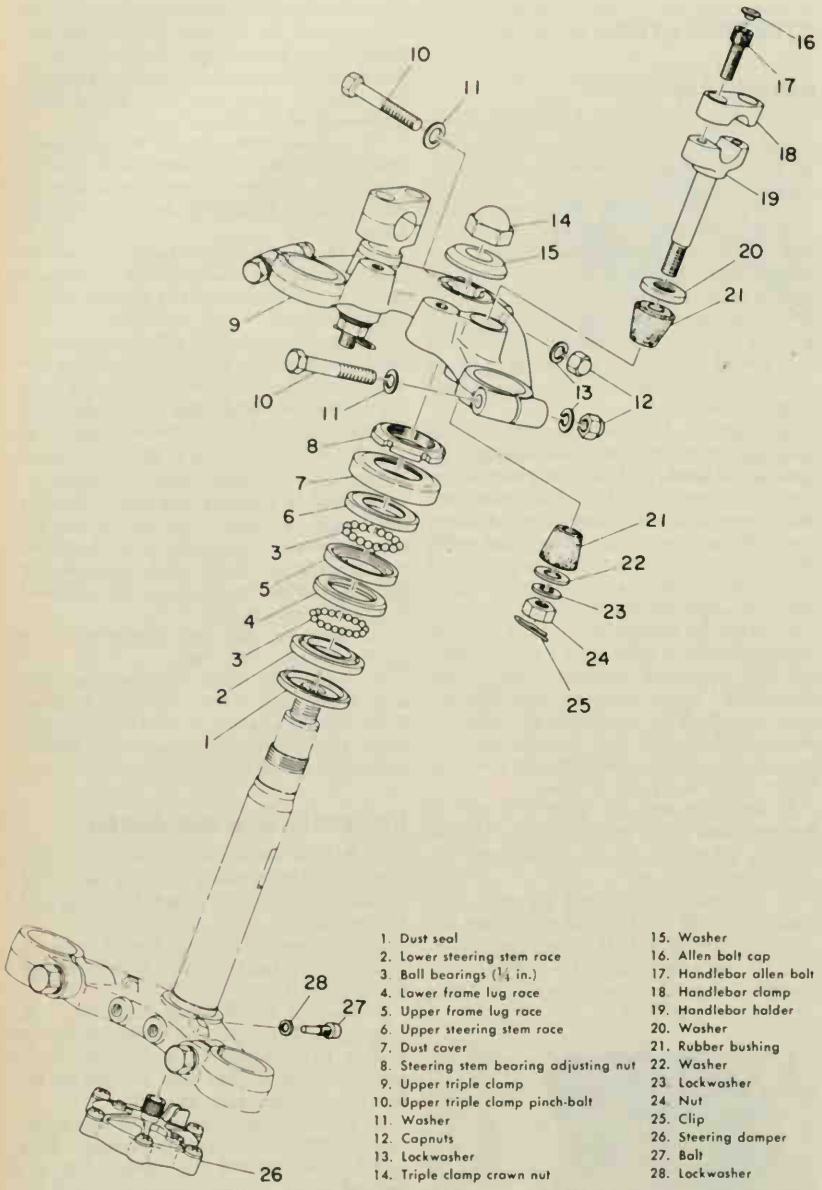
Inspection and Installation

1. Before removing them, note the number of balls fitted to each race. The number may be different for the top and bottom races.



2. Remove the balls and wash them in a suitable solvent. Clean off the bearing races as well.

3. Inspect the bearing balls for rust, pitting, indentations, flat spots, or cracks. Rather than replacing individual damaged balls, both ball sets should be replaced, and the races as well.



4. The bearing race surfaces should be free of rust or corrosion, and smooth. Run your finger around the races. Any indented marks, ripples, or wear would indicate replacement of the races. If this is necessary, replace the balls as well.

5. The bearing races in the steering lug are removed with a hammer and punch. Installation should be made with a block of wood and a hammer to avoid damaging the races. The bearing race on the steering stem may have to be removed with a hammer and chisel.

6. To install, put a thick layer of bear-

ing grease on the top frame lug race and on the lower steering stem race. Embed the bearings in the grease, ensuring that the correct number of balls are fitted. Install the steering stem replacing the top race, dust cover, and adjuster nut. Tighten the nut until slight resistance is felt, then adjust it so the steering stem will fall to either side of its own weight when released from a few degrees from the centered position.

7. Reassemble the rest of the front end in the reverse of the removal procedure. Check bearing adjustment as described above.

SWING ARM

The swing arm is mounted by means of bushings which tend to wear after many miles. The rate of wear will increase if the machine is used over rough terrain. For street machines, Yamaha recommends replacement of the swing arm bushings every 6,000 miles. However, if a check of the bushings reveals that wear is minimal, this interval can be extended.

Inspection

1. To check the condition of the swing arm bushings, remove the rear wheel and sprocket and unbolt the lower shock absorber mounts.

2. Check for play by grasping the end of the swing arm firmly and attempting to move it from side-to-side. Play should be nil. If there is any, the swing arm should be removed and the bushings replaced.

3. Measure the distance between the top and bottom shock absorber mounts on both sides. The two measurements must be identical, or the swing arm will have to be replaced or fixed.

4. Check that the rear wheel mounting plates are parallel.

The swing arm is most likely to be damaged if the machine is operated for any length of time with a broken or otherwise defective shock absorber.

Removal and Installation

1. Remove the rear wheel, sprocket hub, and chain guard. Unbolt the shock absorbers from the swing arm.

2. Remove the swing arm pivot shaft nut. Push or tap out the shaft; turn the swing arm sideways, and remove it from the machine.

3. Remove the dust covers from the ends of the swing arm tube if fitted. Note the location and number of any shims beneath the dust covers.

4. Remove the bushings, tapping them out with a long punch and hammer if necessary. Remove the spacer. Once bushings are removed, they should be replaced. Check the shaft for wear and replace it if there is any evident.

5. Lubricate new bushings with a good chassis grease. Press in one bushing, refit the spacer, and install the other bushing.

6. Install the swing arm on the machine. After tightening the swing arm pivot shaft nut, move the swing arm up and down to ensure that movement is smooth and effortless.

REAR SHOCK ABSORBERS

1. Shock absorbers are sealed units which cannot be disassembled. If defective, they must be replaced.

2. If a shock leaks oil or is damaged in an accident (such as bent shaft, dented body, etc.), replace it.

3. To check a shock which is removed from the machine, place the bottom end on the ground and use the weight of your body to compress it as much as possible. Release the shock and note the rebound behavior. If the shock returns quickly at first, then slowly returns to the normal length, it is serviceable. If it returns to its normal length all at once, it should be replaced. Note that shock absorbers should always be replaced in pairs.

SERIAL NUMBER LOCATION

In order to prevent possible confusion when ordering parts, always refer to the engine and frame serial numbers.

The frame number is stamped on the right side of the steering lug, while the engine number is located on a raised boss just behind the right cylinder on the top of the crankcases.

MAINTENANCE

NOTE: *Common maintenance procedures are explained in detail in "General Information."*

LUBRICATION

Motor Oil

When the average air temperature is above 5° C (41° F), use Yamalube 4-stroke oil, or SAE 20W-40, service rating "SE," or "SF."

When the air temperature is consistently below 15°C (59°F), use SAE 10W-30, service rating "SE" or "SF."

Straight grades can also be used according to ambient air temperatures as given in the "Recommended Lubricants" chart at the end of this section.

Maintain the oil level between the upper and lower dipstick marks (A and B)

Checking Oil Level

XS400G/SG-ON

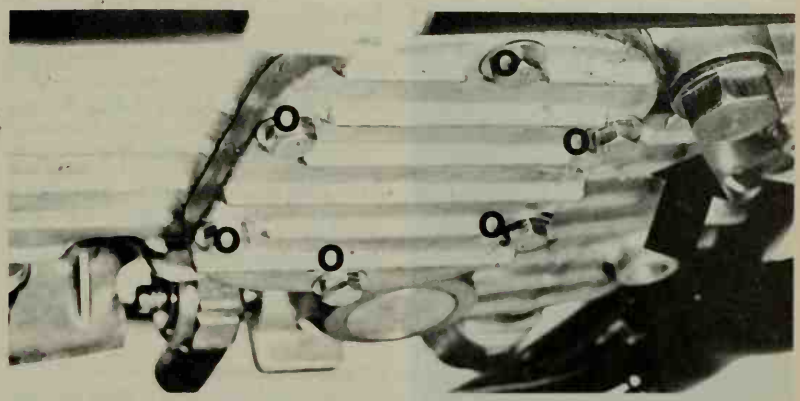
1. A sight glass in the crankcase is provided to enable the rider to check oil level at a glance. When checking, the motorcycle should be parked on the centerstand on a level surface.

2. Oil should be checked when the engine is warm. After shutting it off, let the machine sit for a few minutes.
3. Maintain the oil level between the

Oil level sight glass

upper and lower level marks inscribed on the crankcase. If the oil level is too low, remove the filler cap and add enough oil to bring the level up to the upper level mark. Do not overfill.

OTHER MODELS

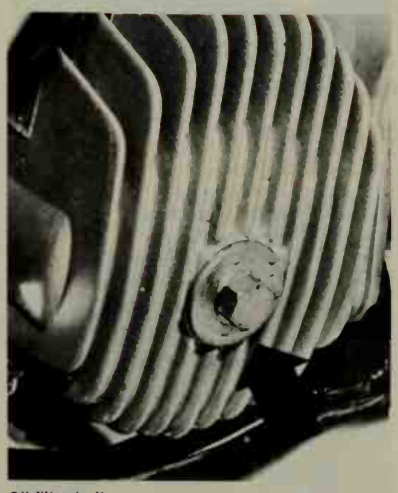


1. A dipstick is provided to check the oil level.
2. The motorcycle should be parked on level ground and put on the centerstand.
3. Unscrew and remove the dipstick and wipe it off. Reinsert the dipstick, allowing it to rest on the treads of the hole. Oil level should be between the maximum and minimum marks on the stick. If the oil level is too low, add enough oil to bring the level up to between the marks. Do not overfill the crankcase.

Changing Oil

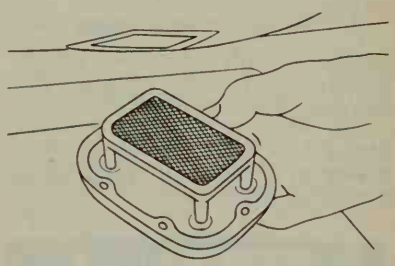
1. The recommended oil change interval is 2,000 miles or every 3 months, whichever comes first.
2. Oil should be changed when the engine is warm. This ensures more complete draining and makes it more likely that the oil will carry off any particulate matter with it.
3. Remove the dipstick. Place a suitable container (at least 2½ qt. capacity) beneath the engine and remove the drain plug. Allow the oil to drain off for several minutes, then install the drain plug and tighten it securely. Proper torque is 25–29 ft lbs.
4. Remove the oil filter screen and the oil filter if it is time to service them (see below).
5. Add 2.1 qts. (2.0 l) of the recommended grade and viscosity oil to the crankcase. If the filter has been changed, add 2.4 qts. (2.3 l).
6. Start the engine and let it run for a few minutes. Then shut it off and check the oil level with the dipstick. Add additional oil, if necessary, to bring the level to between the level marks on the dipstick.

Oil Filter



1. The disposable oil filter element should be replaced at every other oil change: 4,000 miles or every 6 months, whichever comes first.
2. Drain the oil as outlined above.
3. Remove the oil filter housing bolt and remove the housing and filter element. Have a container placed beneath the filter housing prior to removal to catch any oil which might drip out.
4. Clean the inside of the filter housing prior to fitting a new filter element.
5. Install the new element and refit the housing. Tighten the housing bolt to 10–12 ft lbs. *Do not overtighten.*
6. Fill the crankcase with 2.4 qts. (2.3 l) of the recommended grade and viscosity oil.
7. Run the engine for several minutes and check for leaks.

Crankcase drain plug (arrow). Filter screen bolts (0)

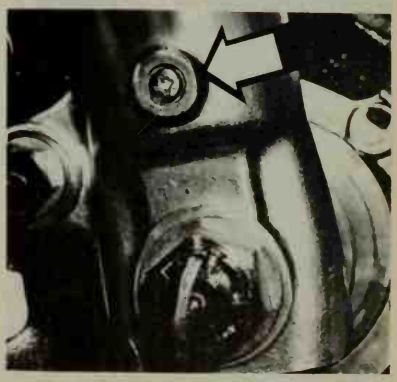


Filter Screen

1. The XS360 and XS400 are fitted with an oil filter screen in the sump. The screen should be removed and cleaned every other time the oil is changed: every 4,000 miles or 6 months, whichever comes first.
2. Drain the oil as outlined above.
3. Remove the six bolts which secure the

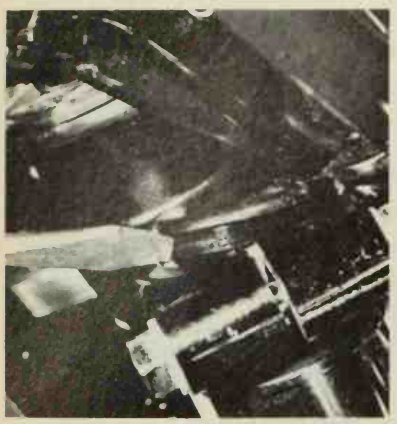
Oil filter bolt

oil filter screen and pull it out. Have a container beneath the screen cover to catch any oil which will drip out.
4. Clean the screen in a safe solvent and



Removing the filter screen

use a reasonably soft brush, if necessary, to remove any foreign matter trapped on it. Check the condition of the gasket and replace it if necessary. Blow dry and reinstall, tightening the cover bolts gradually and evenly. Proper torque is 4.5–6.0 ft lbs.
5. Refill the crankcase with oil. Check for leaks.



Front Forks

1. Yamaha fork oil, SAE 20W motor oil, or SAE 10W-30 motor oil is recommended for all forks.

Front fork oil drain plug

Oil viscosity can be varied if slightly stiffer or less stiff fork action is desired. Special types of oil designed specifically for motorcycle forks can also be used, although care must be taken to flush the forks thoroughly when changing types or brands of fork fluid, since some may be incompatible with others.
2. After an initial change at 2,000 miles, the fork oil should be changed at 10,000 miles intervals.

Removing the rubber fork cap

3. Fork capacities are as follows:

XS360 XS400D XS400-2E	130 cc (4.4 oz.)
XS400E XS400F, 2F XS400G, SG-ON	142 cc (4.8 oz.)

Note that the amounts shown are to be added to each fork leg.

4. Support the front wheel off the ground by placing a jack or the like beneath the engine.

5. Remove the rubber caps at the tops of the fork legs. Press down the fork caps slightly with a screwdriver or similar instrument, and remove the snap rings. Remove the fork caps. Pull out the fork springs.

6. Place a suitable container beneath one of the fork sliders and remove the drain screw. After most of the oil has drained off, pump the slider up and down a few times to

Fork filler cap

remove any oil remaining in the forks. Check the condition of the drain plug gasket and replace it with a new one if necessary. Refit the drain screw and tighten it securely.

Repeat the procedure with the other fork leg.

7. Examine the drained oil. If it contains water or is exceptionally dirty, it may be that the fork dust covers are damaged and allowing foreign matter to get past. This will also damage the fork seals quickly. Check that the dust covers are properly secured and replace them if they are cracked, ripped, or otherwise damaged.

8. Add the proper quantity of oil to each fork leg.

9. Check the condition of the fork cap o-rings, and replace them if they are damaged. Refit the springs, fork caps, snap rings and rubber caps.

10. After several miles of operation, check the area around the fork slider seals for leaks or seepage. Even a minimal amount of seepage will require replacement of the seals. A coating of grime building up in this area over a period of time is also indicative of ineffective seals.

Chassis Lubrication

1. The swing arm pivot is fitted with two grease nipples which should be lubricated with chassis grease every 2,000 miles. Apply grease until it shows at both ends of the swing arm pivot.

Swing arm grease fitting

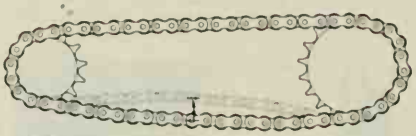
2. Wheel and steering head bearings are lubricated with bearing grease, the service interval being 8,000 miles.

SERVICE CHECKS AND ADJUSTMENTS

Drive Chain

1. On 1976–78 models, the chain should have about 10–20 mm (0.4–0.8 in.) of total up-and-down free-play measured in the middle of the lower chain run.

On 1979–81 models, chain free-play should be 30–35 mm (1.2–1.4 in.).



2. Before checking or adjusting the chain slack, the following conditions should be met:

a. The motorcycle should be placed on both wheels with a rider sitting with his weight on the seat.

b. The transmission should be placed in neutral.

c. The chain should be clean and well-lubricated.

d. The chain should have been checked for any tight spots by slowly rotating the wheel and checking for variances in the chain tension at different points. If a tight spot exists, the chain tension should be adjusted to the prescribed free-play at the tight spot. Note, however, that such a condition is indicative of a worn chain and probably worn sprockets, which should be replaced as soon as possible.

Chain play is the total up and down movement measured in the middle of the lower chain run

Chain adjusting bolt and swing arm alignment marks

3. To adjust the chain, first back off the rear brake adjuster nut on drum rear brakes.

4. Remove the axle nut cotter pin and loosen the axle nut several turns. Loosen the locknut on each chain adjuster bolt.

5. Turn each of the adjuster bolts in or out by equal amounts until the chain tension is approximately correct.

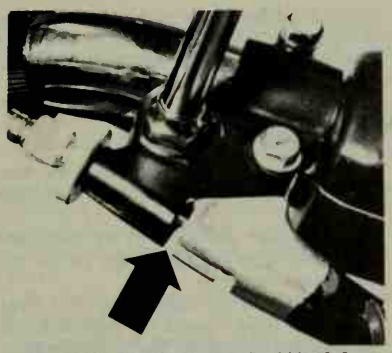
6. Check wheel alignment by means of the aligning marks inscribed on both sides of the swing arm. Be sure that both adjusters are lined up with the same mark on each side. If not, turn one of the adjuster bolts in or out so that alignment is achieved.

7. Tighten the axle nut and adjuster bolt nuts and check the chain tension. Correct if necessary. After adjustment is correct, torque the axle nut to 50–72 ft lbs.

Fit a new cotter pin. Readjust the rear brake on drum brake models.

Clutch

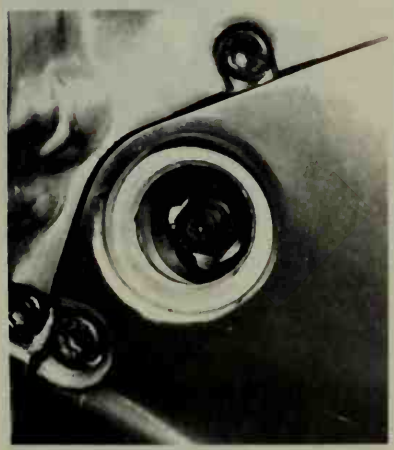
1. Cable adjustment must always be maintained at the proper specification. If the cable has insufficient free-play, the clutch will slip and rapidly burn out. If it has too much play, the clutch will not completely disengage, resulting in hard shifting and creeping at stops.



2. Use the cable adjuster at the handlebar to maintain the correct amount of cable slack. The clutch hand lever should be able to be moved 2–3 mm (0.08–0.12 in.) measured between the lever and the lever holder before the clutch begins to disengage.

If clutch operation is not satisfactory after making this adjustment, proceed as follows:

3. Screw the cable adjuster at the lever in all the way thus increasing cable free-play.

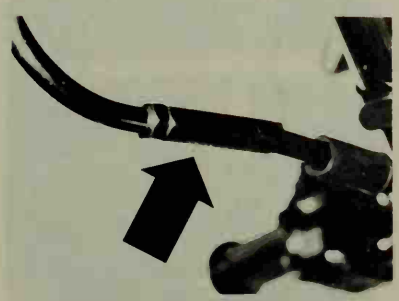


4. Remove the clutch adjuster cover plug. Loosen the clutch adjusting screw locknut.

5. Turn the adjusting screw clockwise until a slight resistance is felt, then turn it counterclockwise ¼ turn. Holding the screw in this position, tighten the locknut.

Clutch cable free-play (arrow) should be 2–3 mm (0.08–0.12 in.)

6. Turn the cable adjuster out until there is about 2–3 mm (0.08–0.12 in.) of free-play in the hand lever. Tighten the locknut on the cable adjuster.



Clutch adjuster screw and locknut

Throttle Cable

1. The throttle cable is fitted with an adjuster at the twist-grip. The twist-grip should be able to be rotated approximately 10–15° (3–5 mm [0.12–0.20 in.]) before the throttle slides begin to open.

2. Use the cable adjuster at the handlebar to make and maintain this adjustment. To check that the cable has sufficient slack, start the engine and turn the forks slowly from lock-to-lock. Idle speed must not increase. If it does, it indicates that the cable has insufficient free-play, is incorrectly routed, or is binding at some point.

3. For complete carburetor adjustments, refer to "Tune-Up."

Throttle cable adjuster

Brakes

FRONT DISC

Disc brakes need little attention other than a periodic check of the fluid level and of pad wear:

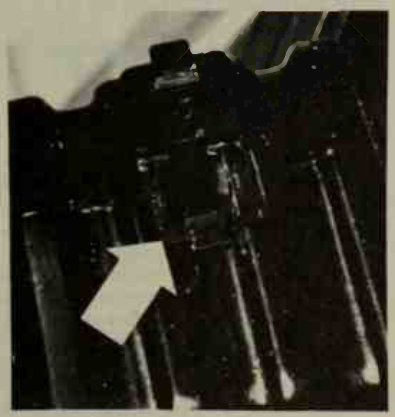
1. Check the brake fluid level relative to the lower level line inscribed on the see-through master cylinder reservoir. If the fluid level is below the inscribed line, add enough DOT 3 type brake fluid to bring the level up to the mark. Reinstall the master cylinder reservoir cap and tighten the screws securely.

NOTE: *The fluid level will drop slightly as the pads wear.*

2. To check brake pad wear, remove the wear indicator cap on the caliper. The pads should be replaced as a set if either of them is worn to the red limit line inscribed on them.

Refer to "Chassis," for brake system service procedures.

3. If the brake lever feels spongy, or if brake effectiveness has been reduced, a possible cause is air bubbles in the lines. To remedy this, bleed the system. This procedure can also be found in the "Chassis," section.

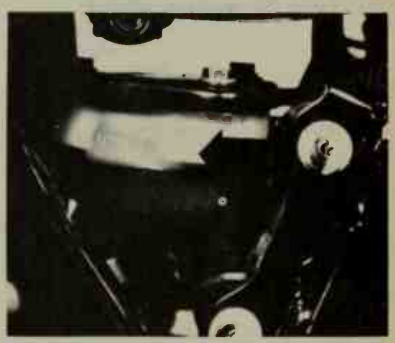


4. The brake lever should have about 13–25 mm (0.5–1.0 in.) of movement which is measured at the tip of the lever.

Lever movement is adjustable by means of an adjusting screw near the lever holder. Once set properly, the lever travel will not ordinarily need readjustment. If lever travel becomes excessive, it is more probable that

Front master cylinder brake fluid level line

the system needs to be bled or has some other fault. Adjusting brake lever travel will not remedy any brake system shortcomings.



Check brake pad wear here

Brake lever adjusting screw

REAR DISC

1. The transparent master cylinder allows inspection of the fluid level without removing the master cylinder cap. If the fluid level is below the level mark, remove the cap and diaphragm and add enough DOT 3 brake fluid to bring the level up to the mark. Reinstall the diaphragm and cap and tighten it securely.

Rear master cylinder brake fluid level line

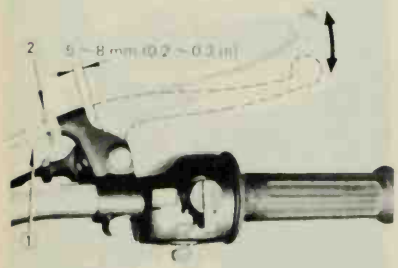
Brake pedal height adjusting bolt (lower) and brake rod adjuster locknut

2. Pad wear can easily be checked by visual inspection. Replace the pads as a set if either of them is worn to the red limit line.

3. To adjust brake pedal height and free-play, loosen the height adjuster bolt locknut.

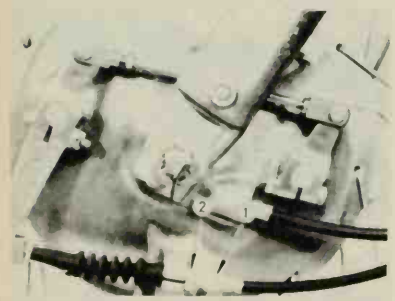
Turn the adjuster bolt in or out so that the top of the pedal is about 12–18 mm (0.5–0.7 in.) below the top surface of the footpeg rubber. Tighten the adjuster bolt locknut.

Loosen the brake rod adjuster locknut and turn the brake rod until there is noticeable free-play between the rod and the master cylinder. Turn the brake rod in until it just touches the master cylinder, than back it out about 1½ turns. Tighten the locknut.



CAUTION: *The pin hole mark on the brake rod must not show above the locknut.*

This adjustment should yield brake pedal free-play of 13–15 mm (0.5–0.6 in.).



FRONT DRUM

1. The brake should be adjusted so that the lever has 5–8 mm (0.2–0.3 in.) of free movement measured between the lever and the lever holder before the linings contact the drum.

2. The brake can be adjusted with either the cable adjustor at the brake plate or the adjustor on the handlebar. Loosen the locknut and turn the adjustor out to decrease brake lever movement. It is recommended that major adjustments be made with the adjuster at the brake plate and finer adjustments with the handlebar adjustor.

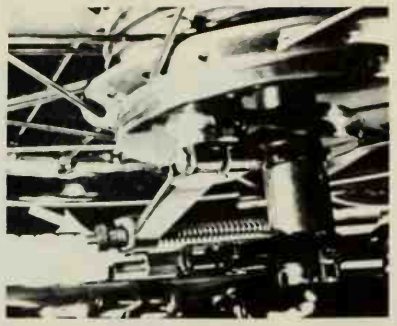
Brake plate adjuster and locknut (1 and 2)



REAR DRUM

1. On early models with rear drum brakes, brake lining wear can be determined by means of the wear indicator pointer fitted to the brake lever on the hub. If the pointer lines up with the red slash mark when the brake pedal is fully applied, the linings are worn as far as possible for effective braking and should now be replaced.

On late drum-brake models, an inspection plug is fitted to the brake plate to allow direct inspection of the linings. They should be replaced when worn to less than 2 mm (0.08 in.). Thickness of new linings is 4 mm (0.16 in.).

The brake pedal should have about 1 inch of movement before the linings contact the drum

Rear brake adjusting nut

2. Observe the angle formed by the brake lever on the hub and the brake rod when the brake is fully applied. When the lever and rod form an angle greater than 90°, the shoes should be checked for wear as they probably are worn to the point of needing replacement.

3. The rear brake should be adjusted so that there is approximately 25 mm (1.0 in.) free-play at the pedal before the linings contact the drum. Adjust by turning the nut on the brake rod. When adjustment has been made, be sure that the nut is seated properly on the brake lever pin. Also, check the operation of the brake light switch.

4. Brake pedal height can be adjusted by means of the stopper bolt and locknut provided. The pedal height can be adjusted to suit personal preference, but it should generally be about ½ in. measured between the top of the rubber footpeg and the top of the brake pedal.

Be sure to check brake adjustment and brake light operation after making any change in the pedal height.

Brake Light Switches

The switches should be checked for operation after the brakes are adjusted. The rear brake light switch and adjuster nut are mounted on a slotted bracket. The rear switch is adjusted by holding the switch and turning the adjuster nut to effect adjustment. Moving the switch up on the bracket allows the brake light to turn on sooner. Moving it down allows the light to turn on later. Do not turn the switch to effect adjustment as the wires will become twisted and may break.

The front disc brake switch is activated by the pressure of the brake fluid in the brake line. This switch is not adjustable; if defective, it must be replaced.

Headlight Adjustment

1. Set the machine about 25 feet away from a wall, preferably of a color which reflects light well.

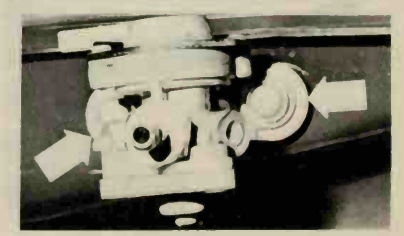
The machine should be off the stand, and with a rider putting his weight on the machine as in operation.

2. Switch on the high beam. The headlight high beam should be parallel to the ground and should hit the wall directly in front of the machine.

Headlight lateral adjustment screw

3. Vertical adjustment is made by first removing the headlight rim anchor screw and removing the headlight by prying at the point provided at the bottom. Slightly loosen the two headlight shell mounting nuts and install the headlight. Adjust the headlight by pivoting the shell up or down as needed. Remove the headlight and tighten the two mounting bolts. Install the headlight and tighten the anchor screw.

4. Lateral adjustment is accomplished by turning the adjusting screw on the side of the headlight. Tighten the screw to move the beam to the right; loosen it to move the beam towards the left.



FUEL SYSTEM

Fuel system maintenance involves cleaning the petcock fuel filter screen, cleaning or replacing the air filter elements, and cleaning the carburetors.

The normal service interval is 2,000 miles.

Petcock

The petcock is the vacuum-activated type which incorporates a mesh filter inside the gas tank.

Petcock securing screws

1. Set the petcock to the "RES" position. Disconnect the fuel line from the petcock and the vacuum line from the manifold.
2. Remove the gas tank. Drain off the fuel.
3. Unscrew the petcock securing nut or two phillips screws depending upon the method of fastening, and pull off the petcock.
4. Clean the filter screen in a solvent. Be sure to remove any foreign matter trapped in the screen as this will impede fuel flow. If the screen cannot be cleaned, or if it is punctured or otherwise damaged, it should be replaced.
5. Check the sealing washer and replace it if it is damaged.
6. Install the petcock. After the tank is refitted, check for leaks before operating the motorcycle.

Air Filters

1. Remove the side covers.
2. Loosen the carburetor clamp. Remove the element case holder screw, take off the securing band, and remove the element case.
3. Remove the case screws and separate the case halves, removing the filter element.
4. Blow out the elements from the inside with compressed air.

NOTE: *After several such cleanings, the elements should be replaced with new ones. The service interval for replacement will depend upon the amount of dirt build-up on the elements.*

5. Refit the elements into their cases and install them.

Carburetors

1. Although major overhaul of the carburetors requires their removal as a unit, the float bowls and jets can be cleaned with the units in place.
2. Make sure that the petcock is shut off ("RES" position). Drain the fuel from the carburetor float bowls by removing the main jet cover bolt from the bottom of the float bowls.

CAUTION: *Do not let gasoline spill on a hot engine.*

3. Remove the four screws which secure each float bowl and carefully lower the bowls until they are clear of the float mechanism.

Carburetor float bowl drain plug

4. Unscrew and remove the main and pilot jets. These are fitted to the float bowl on 360 models and are on the carburetor bodies on 400 models. Blow the jets clear, then reinstall. Clean any foreign matter out of the float bowls. When installing, position the bowls carefully to avoid damage to the floats. Tighten the screws gradually and evenly. Check for fuel leaks before operation.

TUNE-UP

NOTE: *Common tune-up procedures are explained in detail in the "General Information" section.*

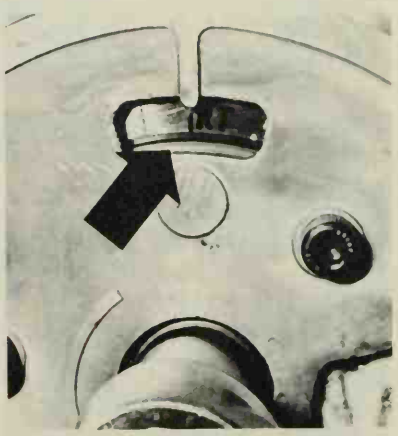
COMPRESSION TEST

1. A compression check should be made before each tune-up since this will provide a general idea of engine condition.
2. It is necessary to have a gauge with the proper adapter (plug holes are 14 mm) if a screw-in type gauge is used. The less expensive "hold in" type gauges can also be used. Use some oil on the rubber tip to ensure a good seal.
3. The engine should be at operating temperature when checking compression.
4. Remove both of the spark plugs and fit the gauge to one of the plug holes.
5. Close the choke and hold the throttle wide open while spinning the engine with the starter motor or the kickstarter. Note the highest compression reading and repeat the test with the remaining cylinder.
6. Compression may vary according to gauge tolerance and several other factors. However, it should normally be between 140 and 170 psi. Both cylinders must be within 15 psi of this range and of each other.

CAM CHAIN ADJUSTMENT

The cam chain tension is automatically regulated. No routine adjustment is required.

VALVE ADJUSTMENT



NOTE: *Valves must be adjusted when the engine is cold.*

1. Turn the fuel petcock to the "RES" position. Disconnect the fuel feed line and the vacuum line from the petcock.
2. Remove the gas tank.
3. Remove the intake and exhaust tappet covers.
4. Remove the alternator rotor cover.
5. The valves for each cylinder are adjusted when the piston for the cylinder is at top dead center on the compression stroke. Use a wrench on the rotor nut so that the "LT" mark on the rotor is aligned with the stationary timing mark on the crankcase cover. Check that there is clearance at both valves for the left cylinder. There should be a little movement in both rocker arms. If there is not, it indicates that the piston is at TDC on the *exhaust* stroke. If this is the case, rotate the engine through one full turn of the rotor and align the "LT" mark again. This should be TDC on the compression stroke.

Alternator rotor cover allen bolts

Checking valve adjustment

Alternator rotor aligned with timing mark to position right-side piston at top dead center

6. Check the clearance between the rocker arm and the top of the valve for both intake and exhaust valves using the appropriate feeler gauges.

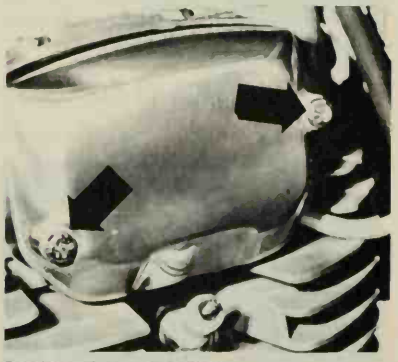
Clearances should be 0.08-0.12 mm (0.003-0.005 in.) for the intake, and 0.16-0.20 mm (0.006-0.008 in.) for the exhaust.

If the clearance is correct, a feeler gauge of the proper thickness will be a light slip fit between the rocker arm and valve.

7. If adjustment is necessary, loosen the adjuster locknut and turn the adjuster screw so that clearance is correct. Again, the feeler gauge should be a slip fit between the rocker arm and valve. Hold the adjuster in place and tighten the locknut securely. Recheck the clearance.
8. Turn the rotor one full turn so that the "RT" mark (for the right cylinder) is aligned with the stationary timing mark. Check that the piston is at TDC on the compression stroke by noting clearance at both valves as before. Check the right cylinder valves in the same manner.

NOTE: *When the engine is at operating temperature, the valves should be very quiet. Ticking from properly adjusted valves is sometimes due to the valve stem becoming indented by the valve adjuster screw. This should be confined to older machines, since the valve ends are stellite-coated. Indentations on the valve stem will give a false feeler gauge reading: the clearance will be too large. Valves can be checked by visual inspection by unscrewing the adjuster.*

While more annoying than harmful, the only safe remedy for this situation is replacement of the valves.



CONTACT BREAKER POINTS

Location

The contact breaker points are opened and closed by a cam on the end of the camshaft and are located beneath a cover on the left side of the cylinder head.

The timing advance mechanism is located behind the breaker point plate.

The condensers are mounted near the coils.

Breaker point cover screws

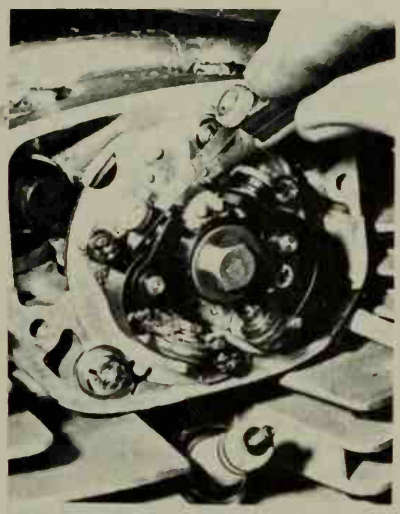
Replacement

1. Points sets purchased complete with the breaker plate can be easily replaced by disconnecting the primary wires at the connectors beneath the gas tank, removing the two large breaker plate securing screws, and carefully pulling off the old plate and points. After installing the new points and plate, the breaker point gaps and the ignition timing must be set (see below).
2. If the points are purchased separately, disconnect the primary wire at each point set, remove the securing screws, and remove the old points. When installing new points, note that the proper installation of the insulating washers at the primary terminal is critical. If improperly installed, no spark will occur. There is a small insulating tube which fits around the terminal bolt and two insulating washers, one immediately on either side of the terminal bracket. All connectors (primary wire, points spring) are made on the outer sides of these washers (i.e., no connector must touch the bracket, which is a ground).
3. New points may have a protective coating on the contact surfaces to prevent oxidation. Clean off these surfaces with a non-oily

Primary wire connectors beneath the gas tank

solvent before attempting to start the machine.

4. If the motorcycle will not start immediately after installation of new points, check that the primary wire connections under the gas tank are tight, that the insulating washers at the primary terminal are properly installed, and that the contact surfaces are thoroughly cleaned.



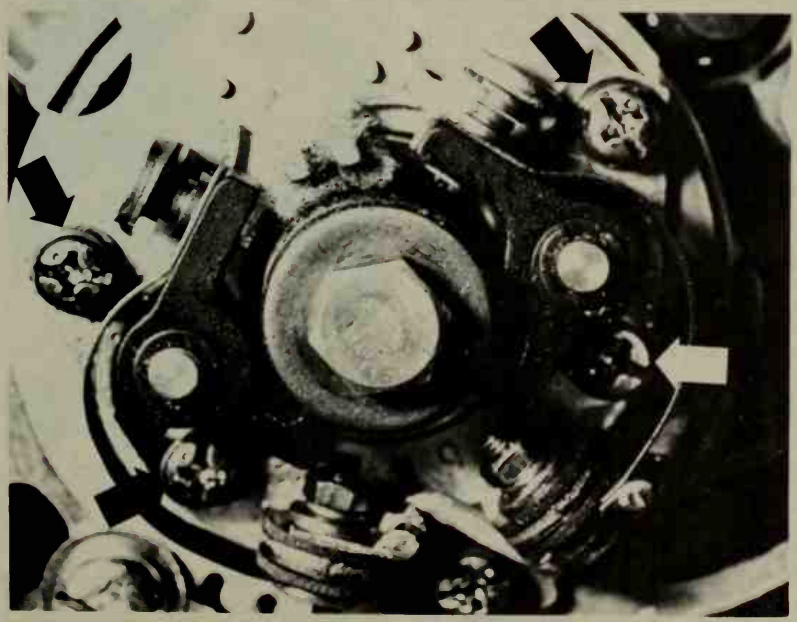
5. Condensers are easily replaced after disconnecting the lead near the coils and removing the screw which secures the condenser.

Gapping

Periodic gapping is necessary to compensate for erosion of the contact surfaces due to electrical arcing and for wear of the fiber heel. As the heel wears, the points will open later relative to the rotation of the crankshaft, thus retarding the timing slightly.

Points should be filed (if necessary) and cleaned before gapping.

1. Remove the points cover.
2. Turn the engine over until one of the two sets of points is fully open.
3. With the proper feeler gauge blade, check the gap. The proper specification is 0.3–0.4 mm (0.012–0.016 in.), and the blade should be a slip fit between the points if the gap is correct.



Checking point gap

4. If adjustment is necessary, loosen the screws which secure the point set to its plate, and use a small screwdriver at the pry point provided to adjust the gap.

CAUTION: *Loosen the screws just enough to allow the points to be moved. If loosened too much, the points will snap shut instead of holding the gap.*

5. Tighten the screws and recheck the gap. It may change slightly when the screws are tightened.
6. Repeat the procedure with the remaining points set. Try to adjust both sets so that the feeler gauge blade has the same "feel" in both sets. This will help to ensure accurate timing.
7. If it is not possible to gap the points correctly, the fiber heel is evidently worn; the points should then be replaced.

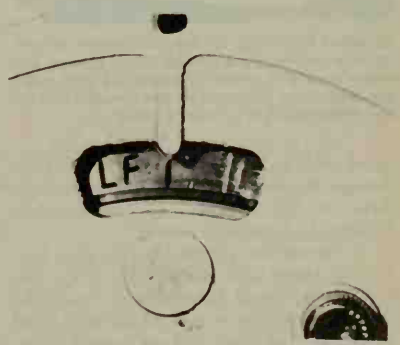
Loosen the screws indicated by arrows to adjust the point gap for both point sets

Lubrication

1. On all models it is necessary to occasionally lubricate the cam follower fiber heel and the pivot point of the contact breaker. This minimizes wear and ensures that the timing will remain accurate for a longer period. A worn heel will retard the timing.
2. A small dab of grease (high melting point, if possible) should be applied to the lubricator wick so that the lubricator can distribute it onto the breaker cam. A drop of engine oil should be applied to the pivot point.
3. In both cases it is imperative that care be taken to keep the lubricant away from the points contact surface.
4. The lubricating wick should be adjusted so that it just contacts the breaker cam.

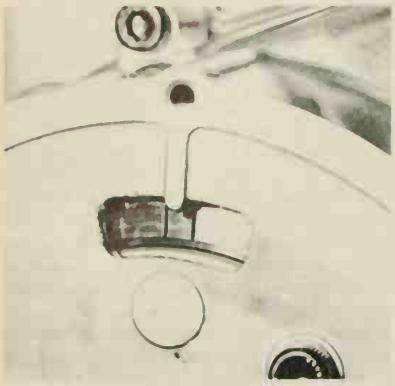
IGNITION TIMING (BREAKER POINT MODELS)

All models except the XS400G/SG and 1981 models are fitted with contact breaker points. Procedures for the transistorized ignition found on the G/SG and 81 models are given in the next section.



The rotor marks are interpreted as follows: "LT" indicates top dead center for the left piston, "RT" for the right piston. "LF" and "RF" are the fixed-advance firing points for the two pistons, which is about 10° before TDC. There are, in addition, two other marks, and these represent the full-advance firing points, which is about 36° before TDC. Timing advance begins at about 2500 rpm.

NOTE: *Points must be cleaned and gapped before checking timing. Dirty points will cause inaccurate readings.*



Remove the points cover and observe the breaker plate. Note that the points for the left cylinder (orange lead) are mounted directly to the large breaker plate, while the points for the right cylinder (grey lead) are mounted on a smaller moveable plate. Therefore, the *left* cylinder timing must be set *first*, since adjustment involves turning the entire breaker plate, which will alter the timing of the right cylinder as well. The points for the right cylinder are adjusted by moving only the points themselves.

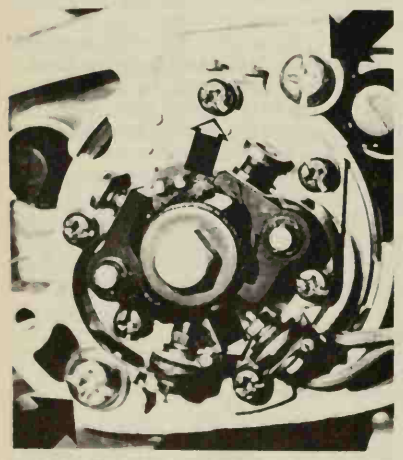
Dynamic Timing

1. Park the bike on the centerstand in a well-ventilated area.

Static firing point for the left-side cylinder

Full advance firing point is indicated by two lines

2. Remove the points cover and the alternator rotor cover. Clean and gap both sets of points as previously described.



3. Hook up the strobe light according to the manufacturer's instructions to pick up impulses from the left cylinder.

4. Start the engine and adjust the idle speed, if necessary, to 1,200 rpm.

5. Aim the timing light at the marks on the alternator rotor visible through the cutout. At idle, the "LF" mark on the rotor should align with the stationary timing mark.

6. To check the ignition timing at full advance, increase engine speed until the motor is turning 2,500–3,000 rpm. At this point, the stationary timing mark should be between the two full advance marks scribed onto the alternator rotor.

7. If adjustment is necessary, loosen the two large base plate screws, and rotate the entire plate so that the proper marks align at the specified rpm. Establishing this alignment at full advance is recommended. Tighten the base plate screws.

To adjust the timing for the left cylinder, loosen the two breaker plate screws (large arrows) and rotate the entire plate. To adjust the right cylinder, loosen the two point screws (smaller arrows) and move the right cylinder's points

8. Repeat the procedure, this time having the strobe light pick up the *right* cylinder. If adjustment is necessary, loosen the two small phillips screws which secure the points set to its plate, and use a small screwdriver at the pry point provided to move the set so that proper mark alignment is achieved. Tighten the screws.

9. If it is not possible to achieve full advance alignment without moving the base plate or the right points set all the way to the end of their range of allowable travel, it is possible that the points are either incorrectly gapped, or that they are worn to the point where they must be replaced.

Static Timing

1. Remove the points cover and the alternator rotor cover.

2. Clean and gap both sets of points as described previously.

3. Connect one lead of the tester or test light to the primary wire terminal for the left cylinder (orange lead), and the other tester lead to ground on the engine or frame.

4. If the test device is not self-powered, turn the ignition switch *on* and be sure the kill switch is in the middle position.

5. Turn the engine over in the normal direction of rotation until the "LF" mark aligns with the stationary timing mark. The test instrument should react at the instant these marks align, indicating that the points have opened. If they do not, loosen the two large screws which secure the points base plate and rotate the plate so that the points just open when the timing marks are in alignment. Tighten the base plate screws and recheck the timing.

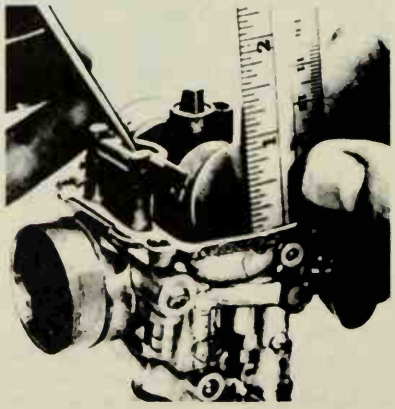
6. Repeat the procedure with the right points set. If adjustment is necessary, loosen the two screws which secure these points to their mounting plate and use a small screwdriver at the pry point provided. Tighten the screws and recheck the timing.

IGNITION TIMING (XS400G/SG,H)

Because of the transistorized spark unit which is used in place of the more conventional breaker points, ignition timing for these models need not be checked unless the pick-up unit is removed.

If a check is required, note that the "LF" timing mark on the rotor should align with the index mark at 1200 rpm. Dynamic timing (using a strobe light) is the only method of checking the timing. Adjustment is not possible. If the marks are not properly aligned at the given speed, the only cause would be a loose spark unit rotor bolt.

CARBURETORS

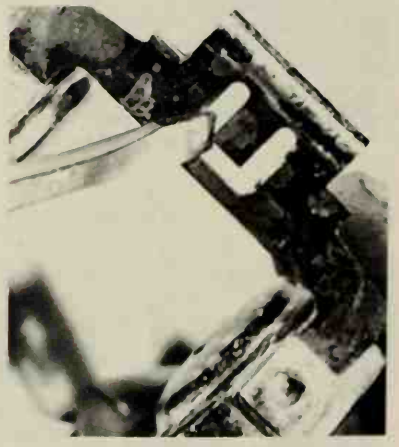


Carburetor adjustments to be made during a tune-up include setting float level, synchronization, and idle speed and mixture.

Adjusting Float Level

1. Float level is a measure of the amount of gasoline which will be in the float bowls during operation. While it is a critical specification, it will not normally need readjustment once properly set. Float level, therefore, need not be checked at every tune-up, but should be attended to from time to time.

2. Remove the carburetors.



3. Remove the float bowls. Remove the gasket. With the carburetor(s) positioned vertically, lower the float until the float arm just touches but does not depress the tip of the float needle. Float level is the measured distance from the bottom of the float to the float bowl mating surface.

Checking float level

4. Float level for each model is given in the "Tune-Up Specifications" chart at the end of this section. Adjust, if necessary, by pushing out the float pivot pin, removing the floats, and bending the float arm tang. Bending the tang towards the carburetor body will increase the float level measurement and vice-versa.

5. Both carburetors must have the same float level. Measure both before changing either. Note that the measured float level will be inaccurate if the float needle tip is worn or if there is foreign matter on the needle seat.

Adjusting the float tang

Synchronization

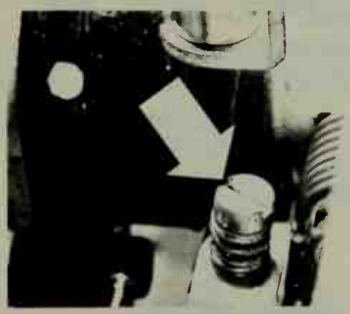
Vacuum gauges are necessary to properly synchronize the carburetors, although a rough approximation can be made by visually aligning the butterflies (see below).

The butterflies are synchronized by means of a single screw located between the two carburetors. Turning the screw simultaneously closes one butterfly while opening the other.

1. Run the engine until operating temperature is reached.

2. Remove the gas tank's rear mounting bolt and raise the tank (fitting a longer fuel

feed line if necessary, so that the synchronization screw between the carburetors is accessible.

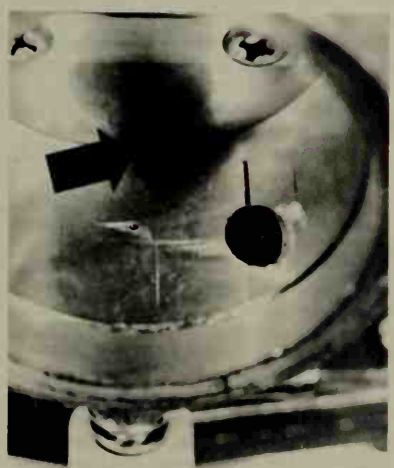


3. The vacuum gauge fittings are on the manifolds. The vacuum gauge fitting for the right cylinder operates the fuel petcock. Disconnect the petcock line from the fitting, and turn the petcock to the "Prime" position for the duration of the procedure.

4. Connect the vacuum gauges.

5. Start the engine and note the vacuum readings. At idle (1,200 rpm) the two cylinders must be within 5 cm Hg (0.2 in. Hg). Adjust, if necessary, by turning the synchronization screw in or out until the vacuum readings for the two cylinders is as identical as possible.

NOTE: *If the vacuum gauges read more than 5 cm Hg (0.2 in. Hg) at 1,200 rpm, check the compression, spark plugs, ignition timing, and valve clearance.*



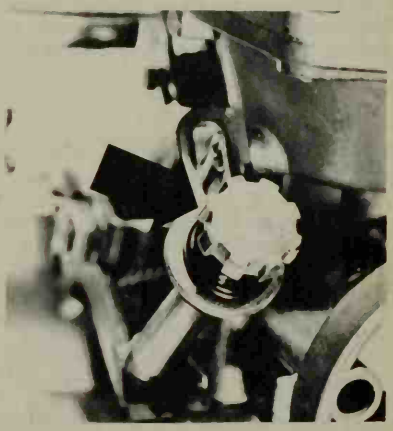
6. If vacuum gauges are not available, a rough method of synchronizing the carburetors may be carried out. Remove the carburetors as a unit from the motorcycle. Look into the engine side of the carburetors and note the relative positions of the edges of the butterflies in relation to the small by-pass passages in the bottom of the bores. Both butterflies should be in the same position relative to these by-pass holes.

Carburetor synchronizing screw

Manifold vacuum fitting (left side)

Aligning both butterflies relative to the bypass outlet is a rough way to synchronize the carburetors

Idle Speed and Mixture



1. The idle mixture is controlled by a pilot screw fitted to each carburetor. The screws are fixed in position by means of idle limiter caps. This is designed to reduce emissions. Therefore, it is not generally necessary to adjust the pilot screws.

2. If the limiter caps are missing, or if the pilot screws have been removed (as during a carburetor overhaul), pilot screw adjustment is accomplished by screwing the pilot screws in (very carefully) until lightly seated, then backing them out 1½ turns on 360 models and 1¼ turns on 400 models.

3. Idle speed is set by means of the throttle stop screw between the carburetors. Idle speed is 1,200 rpm, and must be adjusted when the engine is at operating temperature.

ENGINE AND TRANSMISSION

NOTE: *Common engine rebuilding techniques and inspection procedures are given under "Engine Rebuilding" in the General Information section.*

ENGINE SERVICE

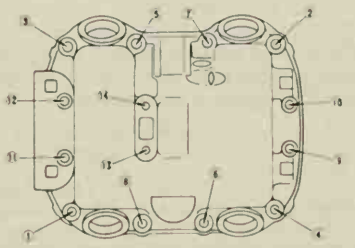
1. The cylinder head, barrels, and pistons can be removed with the engine in the frame.
2. Crankcase cover components such as the clutch, oil pump, kickstarter assembly, alternator, etc., can also be serviced without removing the engine.
3. Service to the crankshaft, transmission, and gear shift components requires removal of the engine.
4. Read each procedure carefully before beginning so that replacement items such as gaskets, o-rings, etc., can be purchased before-hand.

ENGINE REMOVAL AND INSTALLATION

1. Clean and degrease the engine thoroughly before removal. This will minimize chances of foreign matter getting into the crankcase during the disassembly procedure.
2. Disconnect the fuel line from the petcock, the vacuum line from the right manifold, the bolt from the rear of the tank, and remove the gas tank.
3. Drain the crankcase oil. Remove the oil filter housing.
4. Remove the side covers. Remove the air filter boxes. Remove the air filter hoses from the carburetors.
5. Disconnect the throttle cable from the linkage, loosen the carburetor clamps, and remove the two carburetors as a unit.
6. Remove the mufflers and header pipes.
7. Remove the rider footpegs.
8. Remove the rear brake pedal.
9. Remove the gearshift lever from its shaft.
10. Disconnect the spark plug caps and loosen the plugs.
11. Disconnect the tachometer cable from the cylinder head.
12. Remove the engine sprocket cover. Disconnect the clutch cable.
13. Disconnect the breaker point leads and the alternator wires at the connectors.
14. Disconnect the started motor lead from the solenoid.
15. Disconnect the battery ground lead.
16. To remove the engine sprocket, temporarily fit the gear shift lever, engage the transmission, fit the rear brake pedal, apply the brake, and remove the engine sprocket nut. Remove the sprocket from its shaft. It may be necessary to move the rear wheel forward to yield sufficient chain slack to allow this.
17. Remove the engine mounting bolts and take the engine out of the frame.
18. Installation is the reverse of removal. Note the following points:

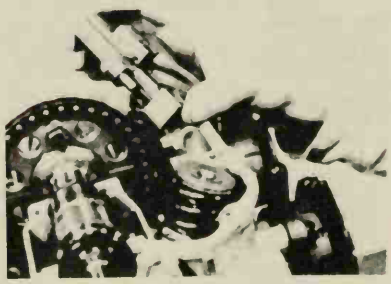
a. Install the engine in the frame from the right side.

b. Tighten the 10 mm nuts to 18-30 ft lbs. Tighten the 8 mm nuts and bolts to 10-21 ft lbs.



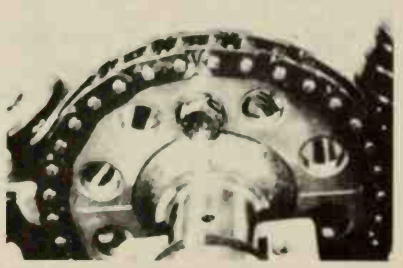
TOP END

Cylinder Head Removal

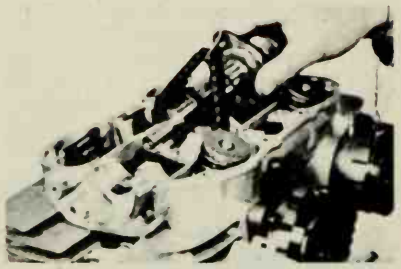


1. Remove the gas tank by disconnecting the fuel line from the petcock and the vacuum line from the manifold and the rear tank mounting bolt.
2. Disconnect the throttle cable at the carburetors. Loosen the carburetor manifold and air cleaner hose clamp screws and remove the carburetors as a unit.
3. Remove the exhaust system. Disconnect the spark plug caps. Remove the plugs.
4. On breaker point-equipped models, disconnect the point leads at the connectors. Remove the breaker point cover. Remove the point assembly. Pull off the timing mechanism. Disconnect the tachometer cable from the cylinder head.

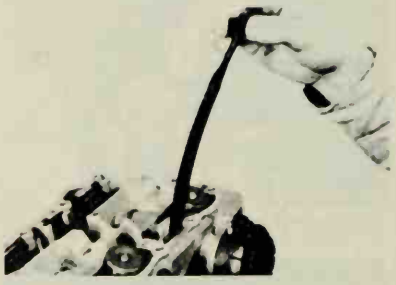
On transistorized ignition models, a special procedure is necessary. Proceed as follows to remove the pick-up coil which is fitted in place of the breaker points:



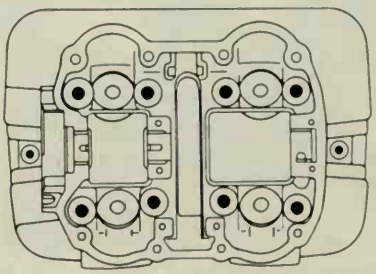
a. Centerpunch the blind plug which secures the pick-up coil cover. Use a 5 mm drill bit to drill the plug.



Cylinder head cover bolt loosening order



Removing the cam chain tensioner assembly



Camshaft sprocket bolt

Removing the camshaft. Note cam chain secured by wire

Removing the cam chain guide

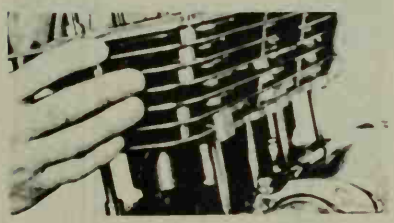
Cylinder head nuts and bolts

b. Cut internal threads 6 mm diameter x 1.0 mm pitch in the blind plug with a proper size tap. Thread in the special slide hammer or a suitable metric bolt, and pull out the plug.

c. Remove the cover screws and take off the cover.

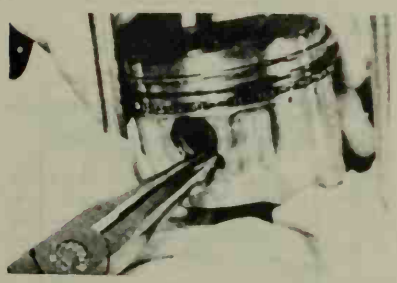
d. Remove the rotor bolt and the rotor.

e. Remove the pick-up coil screws and remove the assembly.



5. Remove the cylinder head-to-frame mounting nuts and bolts.
6. Remove the cylinder head cover bolts. Loosen the bolts gradually and in a cross pattern. If the cover is stuck, tap around the sides with a plastic mallet to free it.
7. Remove the alternator rotor cover.
8. Take out the cam chain tensioner assembly. Note the location of each part.
9. Turn the engine over, if necessary, so that one of the cam chain sprocket bolts is acessible. Remove the bolt. Turn the engine over so that the other bolt can be removed.
10. Loop a length of wire through one of the cam chain sprocket holes and anchor the wire to the engine. Remove the camshaft.
11. Remove the cam chain guides.
12. Remove the cylinder head nuts and bolts. Remove the cylinder head.

Cylinder and Piston Removal



1. Lift the cylinder a few inches off its seat and stuff a clean, lint-free rag or rags beneath the pistons. This is to prevent any foreign matter or pieces of broken piston ring from falling into the crankcase when the cylinders are removed.

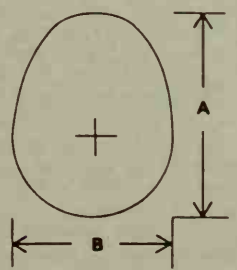
2. Lift the cylinder straight up and free of the studs.

3. With a needle-nosed pliers, remove the wrist pin circlips from the pistons. Push out the piston wrist pins and remove the pistons from the rods.

Removing the cylinders

Removing the piston wrist pin circlip

Support the piston with one hand while pushing out the wrist pin to minimize chances of bending the rod. Push the pin out with stead pressure. Do *not* use an impact method. If the wrist pins resist removal, heat the piston crown gently and evenly with a propane torch until the pins can be easily pushed out.

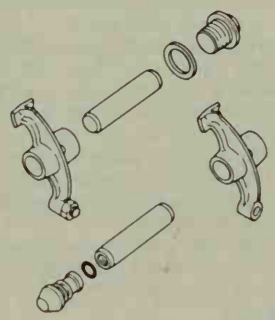


Disgard the wrist pin circlips. New circlips must be used on assembly.

4. Mark each piston so that it can be installed in its original cylinder on reassembly.

Inspection

CAMSHAFT



1. Check the cam lobes for flaking, scoring, or blue discoloration, and replace the cam if any of these signs of damage are present.

Measure cam lobe height (A) and base circle diameter (B)

2. With a micrometer, measure the height of each cam lobe and compare the measurement with the specifications given in the chart at the end of this section.

3. Measure the base circle of each cam lobe. This measurement is taken in a plane perpendicular to the cam height measurement through the camshaft centerline. Refer

Rocker arm assembly

to the specifications chart at the end of this section.

4. Mount the camshaft in a set of v-blocks and measure run-out with a dial gauge. If run-out exceeds 0.03 mm (0.0012 in.), the cam should be replaced.

5. Check the cam bearings for scoring and wear. Check the journals as well. Measure the journal diameters, referring to the specifications chart at the end of this section.

ROCKER ARMS AND SHAFTS

1. The rocker arms are fitted to the cylinder head cover. To remove them, remove the rocker arm shaft covers and grommets. Thread an 8 mm screw into each shaft and pull it out. If the shaft resists removal, use a slide-hammer to effect removal.

2. Check the condition of the rocker arm bores and the corresponding areas of the shafts. Note any blue discoloration which might be due to excessive heat or lack of lubricant. Replace the rocker arms and shafts if this condition exists, or if there are obvious signs of damage, such as scoring.

3. Check the cam contacting pad of each rocker arm for pitting or wear. Replace the arm if wear is evident.

4. Measure the inside diameter of the rocker arm bore and the outside diameter of the shaft. Standard clearance is 0.016–0.054 mm (0.00063–0.00212 in.). If the clearance exceeds 0.1 mm (0.004 in.), replace the components.

CYLINDER HEAD

1. Clean any traces of head gasket material from the cylinder head mating surface. Place a straight edge across the mating surface and check for warpage by attempting to slip feeler gauge blades between the head and straight edge. Standard head warpage is about 0.05 mm (0.002 in.), and maximum allowable warpage is 0.1 mm (0.004 in.). At this point, the head should be milled to restore a flat mating surface.

2. Use a wire brush fitting on a power drill to decarbonize the combustion chambers. The valves should be left in place as this is done, as it minimizes the chance of causing damage to the valve seats.

VALVE ASSEMBLY

Before removing the valves, check their sealing ability by pouring a small quantity of gasoline into each port and allowing the head to sit for about five minutes. If the valves are properly seating, leakage into the combustion chamber will be minimal.

1. To remove the valves, and install them properly, a suitable C-clamp is necessary. Compress the valve springs and remove the split collars, retainers, springs, seals, and spring seats. Inspect the valves, guides, springs, and valve seats in the following manner. Keep each assembly separate so that every piece can be installed in its original location. New valve seals must always be used on assembly.

2. If considerable mileage has been covered, the valve springs should be replaced as a matter of course. Always replace valve springs as a set.

Measure the free-length of each valve spring with a vernier caliper. If any of the springs is more than 2 mm (0.08 in.) less than the standard free-length given in the specifications chart at the end of this section, the springs should all be replaced.

3. Each valve must be free to move up and down in its guide with little resistance. Any sticking or binding as the valve is moved in the guide will indicate that the valve stem or guide is in poor condition.

4. Inspect the valve, paying close attention to the edges of the valve head for pitting, burnt or broken edges, excessive carbon build-up, etc. A certain amount of carbon and lead deposits on the valve face and the top of the exhaust valve are inevitable. Heavy deposits should be carefully scraped off with a dull knife, or a wire wheel, and the valve finished up with very fine emery cloth.

Do not touch the valve seating area during these operations.

If the valve has burnt or broken edges, it must be replaced.

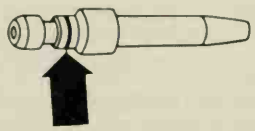
5. Check the end of the valve stem for indented wear caused by the valve adjuster. Although rare, it may occur after long mileage. Since an indentation here will make proper valve adjustments impossible, the valve should be replaced.

NOTE: *The tips and edges of the valves are stellite-coated. Machining for any reason is not recommended. In case of wear, replace the valve.*

6. Carbon deposits should not extend too far up along the valve stem. This would indicate a worn or cracked valve guide.

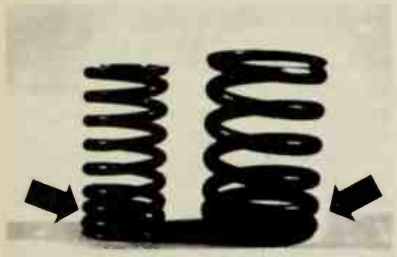
7. Wet, oily deposits on the back of the valve head is indicative of a worn guide or bad seal. Less severe wear to these components show up as brown oil stains on the valve stem.

8. Holding a valve in your fingers, spin it while observing the head. A wobble is indicative of a bent valve. If a dial gauge is available, check the run-out of the head. Replace the valve if run-out exceeds 0.03 mm (0.0012 in.). Run-out is the total indicated dial gauge reading.



Attempt to rotate the valve by hand when it is fully inserted into the guide. If the valve will not rotate easily, or if it sticks as it is turned, it is probably bent.

9. Check valve-to-stem clearance and compare to the specification given. Insert the valve in the guide, holding it about ½ in. off



the seat, check the total amount of allowable movement in two directions using a dial gauge.

Maximum allowable clearances are 0.08 mm (0.003 in.) for the intake valves and 0.1 mm (0.004 in.) for the exhaust valves. If the measured clearances exceed these amounts, replace both valve and guide.

A quick check of the operational worthiness of a valave and guide can be accomplished by dipping the valve stem in oil and inserting it into its guide. Place a finger over the other end of the guide. Pull the valve a little way out of the guide and release it. The valve should be drawn back into the guide by suction if the components are in serviceable condition.

Oversized valve guides are identified by a groove around the upper part of the guide

Valve springs are installed with the close coils (arrows) towards the head

10. Measure the diameter of each valve stem at three places along the length of the valve. Check the measurement against the standard diameter given in the chart at the end of this section, and replace the valve if any of the measurements is below the standard.

11. To replace a valve guide, heat the cylinder head in an oven to a temperature of 212°F (100°C). Drive out the old guide(s) with a suitable drift. Drive in the new guide(s) until fully seated. Use new o-rings.

NOTE: *When replacing valve guides, use the special oversized guides. These are easily identified since they have a groove around the upper part of the guide.*

After installation, ream the new guide(s) with a 7 mm reamer. Clean the inside of the guide thoroughly afterwards.

12. After installing new guides, the valve seat should be recut and the valve lapped in.

13. Check the width of the valve seat on the valve. It should be about 1.0 mm (0.04 in.) all the way around. If narrower or wider than this, or if width varies around the valve, the seat should be recut and the valve lapped in.

NOTE: *Valve springs are progressively wound. When installing them, be sure they are fitted with the close coils towards the cylinder head.*

SEAT CUTTING

1. Use a machinist's dye to check the width and position of the valve seat. Apply the dye to the valve's beveled seating area and a very small amount of grinding compound to the valve seat in the head. Spin the valve back and forth against the seat for several seconds, then remove the grinding compound and inspect the pattern of the seat, from which the dye will have been removed.

2. The valve seat should be about 1.0 mm (0.04 in.) wide and even in width all around the valve. The maximum acceptable seat width is 1.5 mm (0.06 in.).

3. If the seat is uniform in width but is too wide, use a flat cutter, then a 30° cutter to reduce the seat width to within specification.

4. If the seat is centered on the valve face, but is too narrow, use a 45° cutter to increase the width to the proper specification.

5. If the seat is too narrow, and is towards the top edge of the face, first use a flat cutter, and then the 45° cutter.

6. If the seat is too narrow and positioned towards the bottom edge of the face, use a 30° cutter first, then a 45° cutter.

LAPPING

1. Valves should be lapped into their seats if the leakage test shows poor sealing, if the seat has been recut, if the valve edges or seat in the head are pitted, if the motorcycle has covered considerable mileage, or if new valves or guides are fitted.

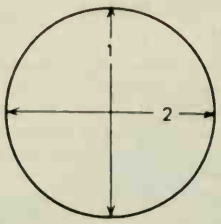
2. Clean off all carbon build-up on the surface of the combustion chamber. Place three small dabs of valve lapping paste around the circumference of the valve head and place the valve into the guide.

3. If you have a lapping tool, use it as the manufacturer directs. Usually the tool will turn the valve back and forth while rotating it around the seat at the same time. Do not use excessive pressure during the operation.

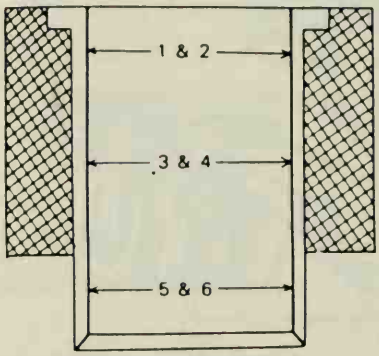
If you do not have such a tool, a piece of thick fuel line placed over the valve stem works just as well. Turn the valve back and forth and rotate it to a new position every few seconds.

NOTE: *Check the condition of the valve face and seat frequently. When a smooth, even finish is evident, stop lapping. Excessive lapping may lead to a pocketed valve.*

4. Remove the valve and clean it thoroughly. Remove any traces of lapping compound from the seat and the combustion chamber. Swab out the guide with a cotton swab soaked in a solvent. Squirt a little oil into the guide so that it may carry away any particles inside.

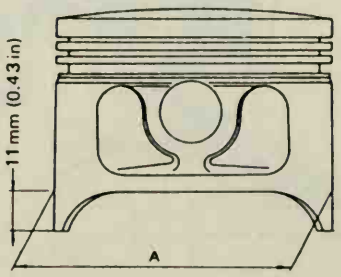


CYLINDERS AND PISTONS



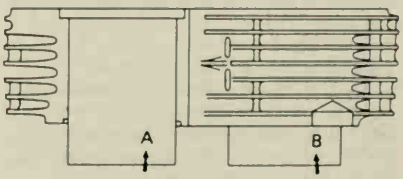
1. Make a visual inspection of the cylinder bore, noting any imperfections. The cylinder walls should be uniformly smooth.

2. With an inside micrometer, measure the diameter of each bore at the top, middle, and bottom. Make measurements in two directions, 90° apart, both parallel and perpendicular to the piston wrist pins.



If the difference between the high and lower measurement in any one direction (taper) is greater than 0.05 mm (0.002 in.), or if the difference between two measurements at any point on the cylinder (out-of-round) exceeds 0.01 mm (0.0004 in.), the cylinders should be bored to the next oversize and fitted with new pistons.

3. Make a visual inspection of the pistons. Scoring, scuffing, or seizure marks on the piston skirts may be removed with a fine grade of emery or crocus cloth if they are not too severe. Sanding should be done in a cross-hatch pattern. If the damage is severe (more than about ½ in. wide), the pistons should be replaced.

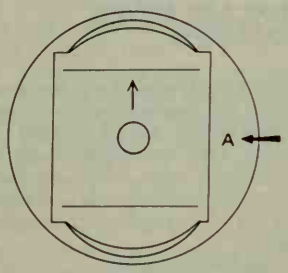


Cylinder bore meesurement points

Measure the piston diameter 11 mm (0.43 in.) above the bottom edge of the skirt and perpendicular to the wrist pin

Cylinder grading mark locations

4. The rings must be free to move in the piston grooves. If they cannot, either they are carbon clogged (which necessitates replacing the rings and cleaning out the grooves), or metal has been pushed into the grooves by a piston seizure. In this event, pistons and rings must be replaced. Carbon-clogged rings are almost always broken when an attempt is made to remove or free them, so be prepared to buy a new set.



5. Pistons are available in four oversizes in increments of 0.25 mm.

To determine piston diameter, use a micrometer and measure the diameter in a direction perpendicular to the wrist pin at a point about 11 mm (0.43 in.) above the bottom edge of the skirt.

Bore the cylinders so that the piston clearance will be 0.030–0.050 mm (0.0012–0.0020 in.).

6. If only the pistons are being replaced, and no boring is being done to the cylinders, note that pistons and cylinders are graded "A" or "B". The piston is marked on the crown, and the cylinders at the cylinder base. Fit "A" pistons with "A" cylinders and "B" pistons with "B" cylinders.

7. Check the condition of the wrist pins. If the pins are blued or show indications of step-wear, they should be replaced. Usually, step-wear can be detected by running a fingernail along the length of the wrist pin. A more conclusive method is to measure the diameter of the pin at three places along its length and compare the readings.

Piston grading mark locations

8. Insert each wrist pin into its piston and check for play of the pin in the piston hole. There must be none. The pin must be a fairly tight fit. If the pin is easily inserted and can be turned or moved vertically with no effort, the pistons should be replaced.

9. Lightly oil each wrist pin and insert it into its connecting rod. Check for vertical play. There should be none. If play exists, or if the rod small end is discolored, the rod and/or pin should be replaced.

10. Check the connecting rods for a bent condition. This can be accomplished with two small rectangular blocks of metal of equal thickness. Insert the wrist pins into the rods, and position the pieces of metal beneath them on either side of the rods and resting on the crankcase. Rotate the engine so that the wrist pin rests on the blocks. Both sides of the wrist pin must contact the metal blocks, or the rod is bent and must be replaced.

11. Before installation, decarbonize the piston crowns. Remove any carbon from the ring grooves with a piece of broken ring or a very thin screwdriver. Be careful not to scratch the grooves.

Carefully check the cylinder, cleaning the bore thoroughly. If considerable mileage has been covered, honing the cylinders and fitting new rings is recommended. If the cylinders are honed, make a strenuous effort to clean them thoroughly afterwards, preferably with very hot soapy water and a stiff brush. This is to remove any abrasive particles deposited by the hone in the course of the operation.

Remove any traces of gasket material from the cylinder base and the head mating surface.

12. Be sure that all oil passages in the cylinder are clear. Check the condition of the cam chain tensioner guides and replace them if damaged.

13. Replace the cylinder base o-rings. Check that any o-rings and the important dowel pins fitted to the cylinders are in their proper locations before installation.

PISTON RINGS

Two checks to be made on the piston rings are side clearance and end-gap. These checks should be made on both new and used rings.

1. Piston ring side clearance for compression rings is checked with the rings installed on the piston. Insert a feeler gauge blade between the ring and the ring groove and check that the clearance is within the specification given for your machine in the "Engine Specifications" chart at the end of this section. If the clearance is too large, the rings or grooves are worn. If too small, metal may have been pushed into the grooves due to a piston seizure. Check that the grooves are not just carboned up. If new rings do not bring the clearance to the proper value, the pistons must be replaced.

2. To remove the rings from the piston, use a ring spreader as illustrated. They are available at most auto stores. Decarbonize the ring grooves.

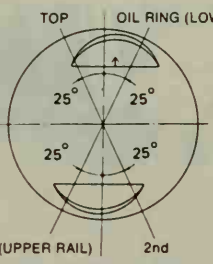
3. To check the ring end-gap, ensure first

Removing piston rings with an expander makes breakage unlikely

that the cylinder bore is not excessively worn. Place each ring, in turn, into the bottom of its cylinder and push it in an inch or more using the piston skirt to align the ring in the bore. Measure the end-gap with a feeler gauge. If the end-gap is larger than the service limit, the rings must be replaced. If the measured end-gap of new rings is too large, the cylinder is worn and should be bored to the next oversize.

If new rings are fitted and the end-gap is too small, the ring ends must be filed. Hold the ring steady as illustrated, closing the ends over a thin, fine file. Do not squeeze the ring, as this is the easiest way to break it. A few strokes of the file will increase the end-gap.

CAUTION: *Do not make more than a few strokes before checking the end-gap again. It is easy to remove too much metal.*



Do not allow the file to slip out of the ring, as this risks breaking it.

4. Roll each ring around its own groove and ensure that this can be done easily. If a ring sticks or binds in the groove, the pistons must be replaced.

Cylinder and Piston Installation

1. When installing piston rings, note that all rings are installed with the manufacturer's mark (the small letter near the end-gap) facing *up*.

NOTE: *Oversize compression rings are stamped "25" "50" "75" or "100" and must be fitted to the correct oversized piston. Oversized oil rings have painted expanders. Red is standard and the four oversizes are brown, blue, black, and yellow in ascending order.*

Stagger the ring end-gaps around the piston as shown

2. To install the three-piece oil ring, install one rail on the piston below the oil ring groove, fit the expander, then move the rail into place. Install the top rail.

3. Use a ring expander to install the rings to reduce the chance of breaking them.

4. Ring end-gaps must be staggered around the piston so that they do not overlap. Position the end-gaps as shown in the illustration. Note that none of the end-gaps are positioned at the very front or sides of the piston.

5. Install the pistons on their connecting rods so that the arrow marks on the crown face the front (exhaust side) of the engine.

NOTE: *Be sure to use new wrist pin circlips.*

6. Slip the wrist pins into place, heating the piston crown as on removal if necessary. Install the wrist pin circlips with a needle-nosed pliers. Be sure each circlips is firmly seated in its groove and arranged so that the circlip end-gap and the cut-out in the piston do *not* align.

7. Lubricate the rings and piston skirts with clean motor oil.

8. Install the o-ring on the oil delivery passage which is around the right rear stud.

9. Install the cylinder base gasket. Check that the cam chain is properly engaged with the crankshaft sprocket.

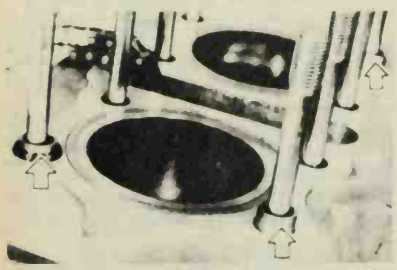
10. Install the cylinder, routing the cam chain up through its passage as the cylinders are lowered. Compress the piston rings with your fingers as the pistons enter the bores. Be sure the cylinders are firmly seated.

Cylinder Head Installation

1. Be sure that the oil delivery passage o-ring is fitted to the right rear stud. Check that the dowel pins are fitted to the right and left front studs. Install the cylinder head gasket.

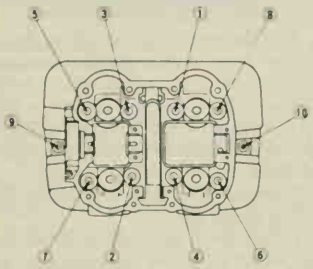
2. Fit the cylinder head over the studs and gradually lower it into position while pulling the cam chain through the cut-out.

3. Install and tighten the cylinder head bolts and nuts. Bolts should be torqued to 7 ft lbs, nuts to 24 ft lbs. Tightening should be done gradually and in a cross pattern beginning with the centermost nuts. Refer to the illustration showing tightening sequence. Lubricate the cam bearings on the head.



4. Pull up the cam chain and slip the cam through. Fit the cam sprocket, so that the

sprocket marks face the left side of the engine, and set the valve timing as described in the following steps.



NOTE: *Using a new camshaft oil seal is recommended. Lubricate the seal lips before assembly.*

Be sure the O-ring is in place around the right rear cylinder stud

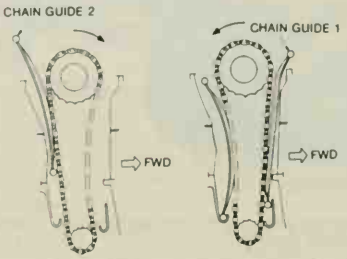
Tighten the cylinder head nuts and bolts in the order shown

Installing the camshaft

Install the cam sprocket so that the lines are flush with the head surface



Use a pin to hold the cam chain tensioner spring in place

5. To set the cam timing, first turn the crankshaft so that the alternator rotor "LT" mark aligns with the timing mark.

6. Position the camshaft so that the locating pin faces upwards. Position the camshaft sprocket so that the two lines on the sprocket align with the cylinder head surface and the "O" mark on the sprocket is at the top.

7. Fit the cam chain over the sprocket without altering the sprocket's alignment.

8. The sprocket bolt holes should be aligned with the cam bolt holes at this point. Fit one of the cam sprocket bolts, tightening it to 13–16 ft lbs. Use a small quantity of a nonpermanent thread-locking compound on the bolt threads is recommended. Turn the engine over until the other bolt hole is accessible, and fit that bolt, torquing it to the same value.

Rotate the crankshaft as shown to install the cam chain guides

9. Thoroughly lubricate the cam lobes and bearings with motor oil.

10. Compress the cam chain tensioner spring and hold it in place with a pin inserted into the hole provided. Install the tensioner, tightening the bolts to 6–9 ft lbs. After properly tightening the bolts, remove the pin.

11. Fit the cam chain guides. It is necessary to rotate the crankshaft to do this, as this will slacken one side or the other of the chain to allow the guides to be slipped into place.

12. If the rocker arms have been disassembled, lubricate the arms and shafts thorougly and install them in the head cover. Note that the threaded end of the shafts must face outwards. Use new o-rings.

13. Use a liquid gasket on the head cover mating surface, then install the cover. Tighten the head bolts gradually and in a cross pattern.

Proper torque is 6–9 ft lbs. for the 6 mm bolts and 15–17 ft lbs. for the 8 mm bolts.

14. Install and secure the rocker arm shaft plugs.

15. Adjust the valve clearance.

16. Carefully turn the engine over to ensure that the valve timing is correct. If resistance is felt when turning the crankshaft, stop immediately and determine the cause. Do not force the crankshaft or bent valves may result.

17. On breaker point models, install the timing advance mechanism, being sure to engage the hole in the mechanism with the pin on the camshaft. Tighten the bolt to 6–9 ft lbs. Fit the breaker point plate. The lead wires pass beneath the top cooling fin. Adjust the ignition timing after assembly is completed.

18. On transistor ignition models, install the pick-up coil assembly. Install the rotor and tighten the rotor bolt to 7 ft lbs. Check the ignition timing. If it is not correct, rotate the pick-up coil base plate until the timing marks align at the specified rpm as outlined in chapter 3. After fitting the pick-up coil cover, install a new blind plug. Do not force the plug in against determined resistance, or the cover may be cracked.

CRANKCASE COVER COMPONENTS

The following sections deal with the removal, inspection, and installation of those components found beneath the left and right crankcase covers. These include the clutch, alternator, starter drive, shift mechanism, kickstarter, and engine sprocket. These components can be serviced with the engine in the frame.

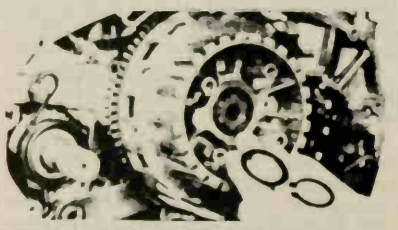
Note the following points:

a. Crankcase covers are secured with allen screws. When installing these screws, coat the threads with a bit of lubricant or antiseize paste to facilitate future removal. Tighten the screws evenly.

b. New cover gaskets (where applicable) should always be used. Remove any traces of old gasket or gasket sealing compound from the cover and crankcase mating surface.

c. During the disassembly procedure it may be necessary to keep the engine from turning over while a component is removed. There are several ways to do this. If the engine is in the frame, place the transmission in gear and apply the rear brake. If the engine has been removed from the frame, loop a length of old drive chain around the engine sprocket and secure the end in a vise. Engage the transmission and the engine will not turn over.

Clutch



REMOVAL

1. Drain the oil.

2. Remove the right-side exhaust system, the rider's footpeg, and the rear brake pedal.

3. Unscrew and remove the right crankcase cover bolts. Remove the cover. If it is stuck, tap around the cover with a plastic mallet until it is freed.

4. Gradually, and in a cross-pattern, unscrew and remove the clutch pressure plate screws. Remove the springs, the pressure

Clutch hub circlip and thrust washer

plate, and the steel and friction plates. Note the order of the steel and friction plates.

5. Remove the pushrod.

6. Remove the clutch hub circlip, thrust washer, and remove the clutch hub.

7. Remove the clutch housing, noting any thrust washers on the engine or hub side of the housing.

INSPECTION

1. Check the condition of the kick-start shaft oil seal. If it leaks, or if the lips show signs of damage, pry the old seal out with a small screwdriver. Press the new seal straight into the cover. Apply some oil or grease to the seal lips before installation.

2. Check the condition of the clutch cover mating surface. Remove any burrs or imperfections with an oilstone.

3. Measure the thickness of the friction plates, and replace them if they are less than 2.7mm (0.106 in.) thick.

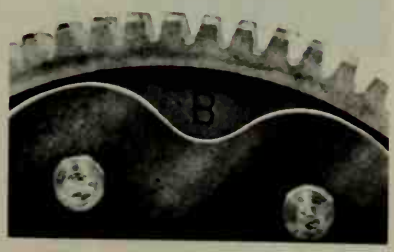
4. Place the steel clutch plates on a flat surface, such as a piece of glass, and check for excessive warpage by attempting to slip a feeler gauge blade between the surface and the plate. Replace the steel and friction plates as a set if warpage exceeds 0.05 mm (0.002 in.).

5. Measure the free-length of each clutch spring and replace them as a set if any are found to be less than 34.6 mm (1.36 in.) long, or if their length varies. If the latter is true, be sure that all of the screws are evenly tightened on assembly.

6. Check the friction plate tabs for wear or damage. Check the clutch housing for indented wear caused by the tabs. Remove any burrs with a file or oilstone.

7. Check the corresponding splines of the clutch hub and steel plates for indented wear.

8. Using a dial indicator, check the pushrod for a bent condition. Replace the pushrod if it is bent more than 0.2 mm (0.008 in.).



9. Check the condition of the clutch gear teeth. Note any pitting or chipping. Check the primary gear teeth as well. If damage to either is noted, replace both. The primary gear is replaced by removing the securing bolt and pulling off the gear.

10. Note the lash letters stamped on the clutch gear and primary gear. The gears should be replaced with reference to these lash letters. Gears should be paired as follows:

Primary gear	Clutch gear
A	C
B	D
C	E
D	F

Primary gear lash notation

Clutch gear lash letter location

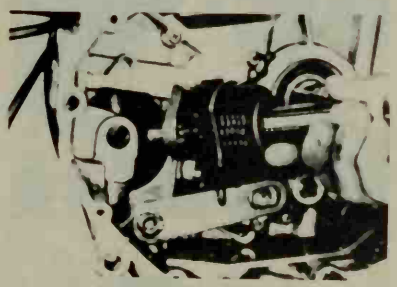
INSTALLATION

1. Installation is the reverse of disassembly. When fitting the clutch plates, alternate steel and friction plates. The last plate installed should be a friction plate.

2. Install the pressure plate so that the arrow on the plate aligns with the arrow on the clutch hub.

3. Tighten the pressure plate screws gradually and evenly.

4. Tighten the primary gear bolt to 29–33 ft lbs.



Kickstarter Shaft

REMOVAL

1. After removing the right crankcase cover, the kickstarter shaft can be removed by pulling it out.

When installing the pressure plate, align the arrow on the plate with that on the clutch hub

Removing the kickstarter assembly

2. When disassembling the shaft components, lay each one out in the order removed to facilitate assembly.

INSPECTION

1. Check the condition of the kickstarter shaft splines.

2. Check the kickstarter gear teeth for chipping or other damage, and replace it if such damage is noted.

3. Check the condition of the shaft return spring. The spring should be replaced if it will not return the shaft quickly to the rest position and hold it securely in place.

INSTALLATION

1. Set the kickstarter gear clip into the groove in the crankcase.

2. Rotate the return spring clockwise and hook it onto the projection.

Gearshift Mechanism

REMOVAL

1. Remove the right crankcase cover. Remove the clutch assembly.

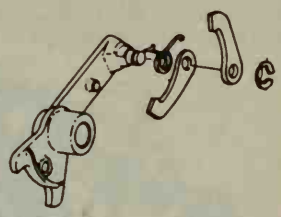
2. Remove the engine sprocket cover (left side).

3. Remove the circlip from the gearshift shaft on the left side of the engine and pull out the gearshift assembly from the right.

INSPECTION

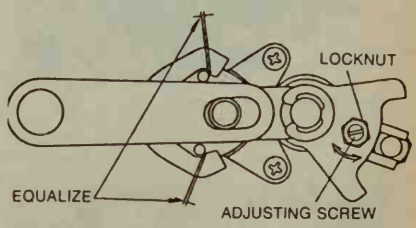
1. Check the gearshift shaft for a bent condition and replace it if it is bent. Check the condition of the gearshift shaft splines.

2. Check the condition of the shift fingers. Note any chipping or wear to the finger ends. Replace the fingers if they are bent or worn.



3. Inspect the shift mechanism springs and replace them if weakened or broken.

INSTALLATION



1. Installation is the reverse of removal. After fitting the mechanism, temporarily install the gearshift lever and test shifting action through the gears.

2. In each gear, check that the shift fingers are equidistant from the shift drum pins. Refer to the illustration. If they are not, loosen the adjusting screw locknut and turn the screw to equalize the distances. Use a non-permanent thread-locking compound on the adjusting screw after the adjustment is correct. Do not forget to tighten the locknut.

3. Check for freeplay in the gearshift lever. There should be none. If any is evident, the return spring is evidently weakened and should be replaced.

Gearshift assembly

Use the adjusting screw to equalize the two clearances indicated

4. Check that the shift finger return spring will hold the fingers firmly against the shift drum pins. If not, replace the spring.

Oil Pump

Refer to "Lubrication System," for oil pump removal, inspection, and installation procedures.

Engine Sprocket

REMOVAL

1. Remove the left-side rider's footpeg. Remove the gearshift lever.
2. Remove the engine sprocket cover screws and take off the cover.
3. Place the transmission in gear and apply the rear brake. Unscrew and remove the engine sprocket nut. Remove the lockwasher and sprocket. It may be necessary to move the rear wheel forward to remove the sprocket from its shaft.

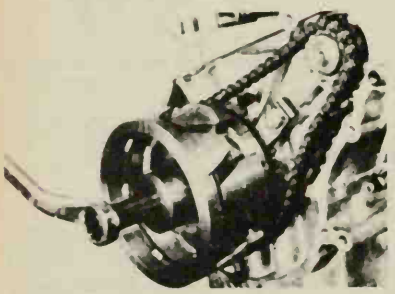
INSTALLATION

Installation is the reverse of removal. Tighten the sprocket nut to 36–58 ft lbs.

Alternator/Starter Drive

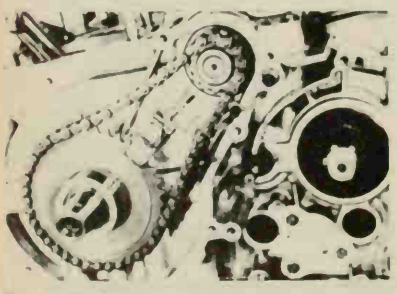
REMOVAL

1. Drain the crankcase oil.
2. Remove the alternator cover.
3. Remove the rotor bolt. Remove the rotor with the special puller. Take out the woodruff key.
4. Remove the sprocket guide and chain guide.
5. Pull off the starter and crankshaft sprocket and chain.



INSPECTION

1. Check the sprockets for wear such as hooking of the teeth. Replace them, along with the chain, as necessary.



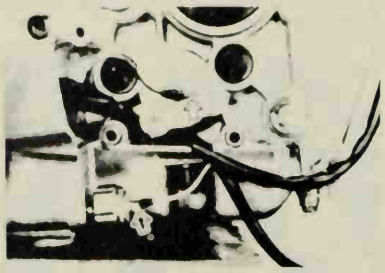
INSTALLATION

Installation is the reverse of removal. The alternator rotor must be turned onto its shaft because of the starter clutch rollers.

Tighten the rotor bolt to 22–25 ft lbs.

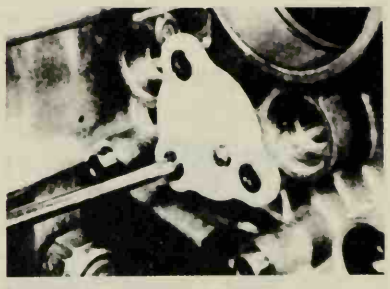
Removing the alternator rotor

Starter drive



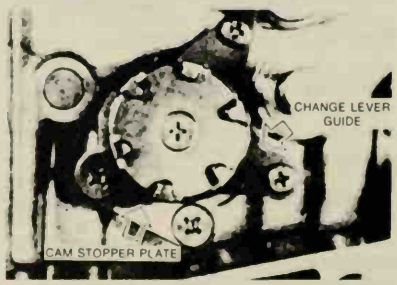
LOWER END AND TRANSMISSION

Splitting the Crankcases



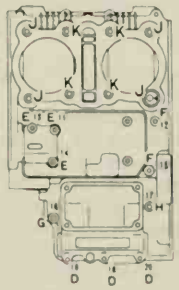
Splitting the crankcases is necessary for service to the crankshaft and connecting rods, transmission gears, and internal shift mechanism.

Removal of the engine is required.

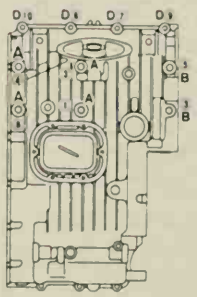


1. Drain the oil. Remove the engine from the frame.
2. Remove the top end components.
3. Remove the left and right crankcase covers and the components therein: clutch, primary drive gear, kickstarter shaft, oil pump assembly, gearshift mechanism, engine sprocket, alternator/starter drive assembly, etc.
4. Remove the starter motor. Remove the breather cover.
5. Disconnect the neutral switch lead and the oil pressure switch lead.
6. Remove the neutral switch cover.
7. Remove the shift drum cam stopper plate and the change lever guide (right side).

Neutral and oil pressure switch leads



Removing the neutral switch cover



8. Remove the upper and lower crankcase bolts. Loosen each bolt ¼ turn, then remove all of them.
9. Remove the upper crankcase half. If it is stuck, first check that all fasteners have been removed. Then tap around the case mating surface with a plastic mallet to break the case free.

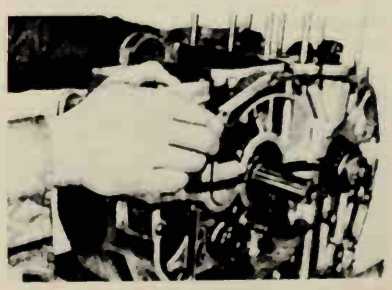
Case Assembly

1. Be sure that the crankcase mating surface is clean and free of all traces of old gasket compound. Minor scratches or burrs can be

Crankcase bolt locations

removed with an oilstone, although care must be taken that the surface is not grooved when doing this.

2. Lubricate all bearing surfaces with motor oil.
3. Be sure that the crankshaft and transmission shafts are properly seated. The transmission shaft bearings are located with set rings. Be sure the shift forks are engaged with their gears.
4. Be sure that all dowel pins between the cases are in place.
5. Apply a thin coat of a liquid gasket compound to the case mating surface. Install the upper case half. After ensuring that it is properly seated, install the crankcase bolts and tighten them gradually and in a cross pattern.

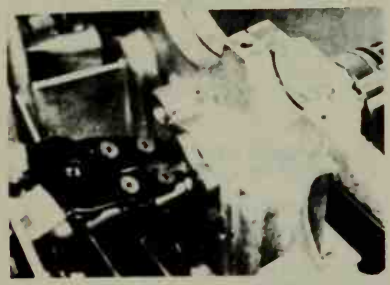


Tighten the 8 mm bolts to 15–17 ft lbs.

Tighten the 6 mm bolts to 6–9 ft lbs.

Transmission/Gear Shift Assembly

REMOVAL



1. Lift the transmission shafts out of the case.
2. Before removing the shift forks, mark

Separating the crankcase halves

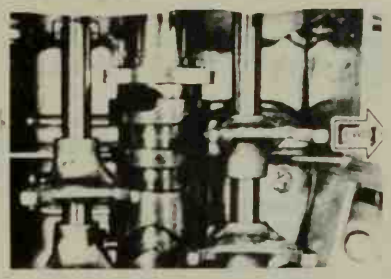
them so that they can be installed in their original locations.

3. Remove the shift fork shaft circlips and push out the shafts with grommets.

4. Move the shift drum as far as possible to one side, then remove the cam plate circlip and the cam plate. Remove the shift drum.

INSPECTION

NOTE: *Do not disassemble the gear set unless inspection shows that replacement of individual gears is necessary. Gear shaft circlips are not reusable and must be replaced with new ones whenever the gear set is taken apart.*



If the gear set is disassembled, carefully lay out each piece in the order it is removed to facilitate reassembly.

1. Flush the transmission shaft bearings with clean motor oil and check operation. Bearing rotation must be smooth, effortless, and quiet. There must be no play between the inner and outer bearing races. If damage is noted, replace the bearings as a set.

2. Check the gear teeth for damage, wear, or pitting. Pay close attention to the very base of the teeth. Gears are surfacehardened, and if this hardened layer is damaged, what is left will not last long. Check the engaging dogs and/or dog slots on each gear for chipping or wear. Check that splined gears are a good fit on their shaft (neither too loose nor too tight) and that the splines on the shafts and on the gears are in good condition. Check that gears with plain bores can rotate freely but are not too loose on their shafts.

Install the cam plate on the shift drum as shown

Shift fork installation

After installing the shift forks (1-4), be sure that the transmission shaft bearing set rings are in place

Check all parts for damage due to overheating or lack of lubricant.

NOTE: *Gears should always be replaced in pairs.*

3. Check that the gear shift fork fingers are not chipped, worn, or bent. If any damage is noted, replace the shift fork in question.

4. Check that each shift fork moves freely on its shaft. If sticking or binding is noted, determine the cause. Check the shafts for a bent condition. Replace any shafts which are even slightly bent.

5. Check the shift fork guide pins for wear. Also inspect the corresponding grooves in the shift drum.

ASSEMBLY

1. Assemble the gear sets onto their shafts. Use *new* circlips.

2. Install the shift drum, fitting the cam plate on the drum as illustrated.

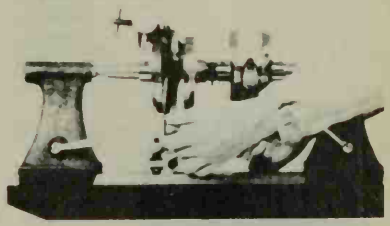
3. Install the shift forks, shafts, and grommets.

4. Be sure that the bearing locater rings are in place in the crankcase.

5. Use new oil seals. Install the output shaft oil seal on the shaft before installation.

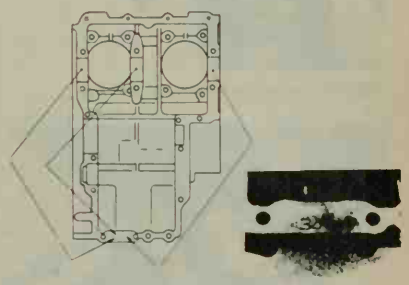
6. Install the transmission shafts, engaging the shift fork fingers with the proper gears as this is done. Assembly is facilitated by ensuring that the transmission is in neutral.

7. Install the shift drum cam stopper plate and the change lever guide. Use a non-permanent thread-locking compound on these screws.



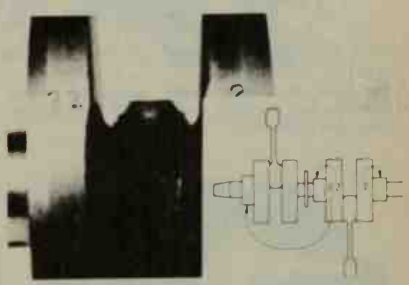
Crankshaft

REMOVAL

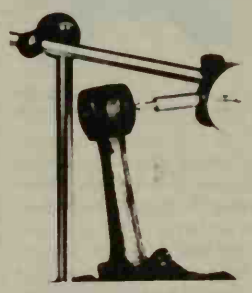


The crankshaft can be lifted out after the cases have been split.

INSPECTION



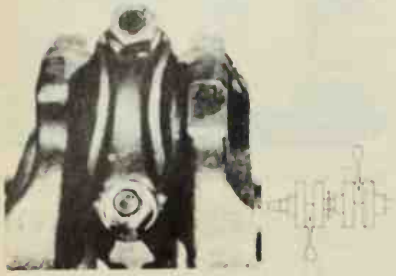
1. Mount the crank in a set of v-blocks and measure run-out with a dial gauge. If run-out exceeds 0.02 mm (0.0008 in.), the crank is bent and must be replaced.



Checking the crankshaft for run-out

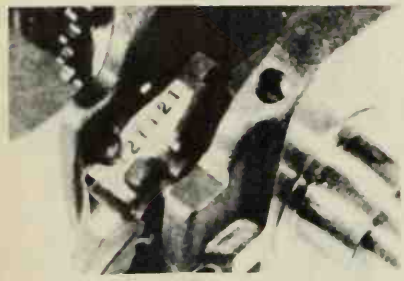
Crankshaft bearing insert number locations

Crankshaft bearing insert number locations on the crank flywheels



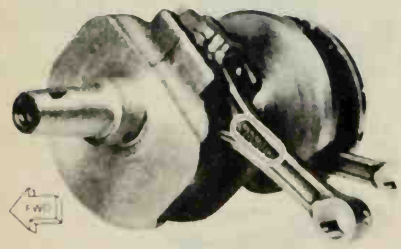
Checking big end axial play

2. Check the crankshaft bearing inserts in the crankshaft for scoring or obvious signs of wear and replace the inserts if the surfaces are not in good condition. The inserts must be free of any defects or they should be replaced.



3. Crankshaft bearings are replaced as a set, and the correct color insert should be selected. Replace bearing inserts with others of the same color. If the color of the old bearing is no longer visible, refer to the following chart:

Note the crankcase number which is stamped on the case and the crank journal number inscribed on the crank flywheel. Compare the two numbers to select the proper bearing insert.



Crankcase No.	Journal No.	Insert
3	1	Blue
4	2	Black
5	-	Brown
-	-	Green

Big end bearing insert number location

Be sure that both rods have the same identification numbers and that the numbers on rods and caps align

When installing the rods, be sure that the "YAMAHA" mark faces the left side of the crank

4. With a dial gauge, check connecting rod side play at the small end. If the movement exceeds 0.5 mm (0.019 in.), the big end bearing should be replaced.

5. Replace big end bearing inserts with inserts of the same color code. If the color is no longer visible on the old insert, select a replacement according to the following chart.

Big End Bearing No.	Crankpin No.	Insert
3	1	Blue
4	2	Black
5	-	Brown
-	-	Green

6. If one or both of the connecting rods is going to be replaced, be sure that the weight codes stamped on the rod and cap match for both rods.

7. Before installing connecting rods on the crankpins, thoroughly lubricate the bearings with motor oil. Install the rods so that the "YAMAHA" mark on both rods faces the *left* end of the crankshaft and the bearing protuberance is towards the *intake* side of the engine. Be sure that the cap numbers align with the rod numbers.

8. Coat the con rod bolt threads with a molybdenum disulphide lubricant and torque them to 24–28 ft lbs.

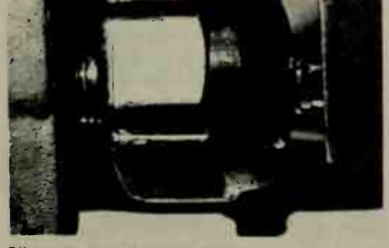
LUBRICATION SYSTEM



OPERATIONAL DESCRIPTION

The oil pump is housed beneath the right crankcase cover and is driven by the crankshaft through a reduction gear. The pump is the "trochoidal" type, meaning that it consists of one rotor turning inside another. The shape of the rotors gives the pump its name and the action of one working against the other pumps the oil.

The oil pump sucks oil from the sump. The oil passes through a course wire-mesh filter before reaching the pump, which removes any large impurities which might damage the pump rotors. This filter is made course so as not to restrict the passage of oil in low temperatures.

The oil pressure relief valve is fitted in conjunction with the pump. The relief valve is pre-set to operate at a pressure above about 70 psi. If the oil pressure reaches this value, the relief valve opens and returns some of the oil to the sump.

After passing through the oil pump, the oil is forced through the replaceable oil filter where microscopic impurities are removed. The oil filter housing is equipped with a by-pass valve. In the event that the filter becomes clogged with filtered material, oil will flow around it to reach the engine's moving parts. This oil, however, will not be filtered, so it is imperative to change the filter at the prescribed intervals to ensure long engine life.

Oil pressure switch location

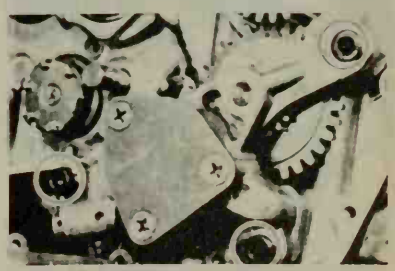
Oil pressure gauge fitting

After leaving the filter, the oil enters the main oil gallery. Here, oil passages allow it to be fed directly to the crankshaft main bearings, connecting rod bearings, and transmission shafts. An oil passage running up through the cylinders and head feeds oil to the camshaft and valve assemblies. The main oil passage is also equipped with an oil pressure switch which monitors the system for pressure failure, and it includes a fitting to attach an oil pressure gauge.

After lubricating the various components, the oil is returned to the sump and the cycle is repeated.

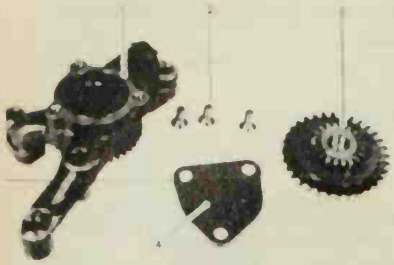
CHECKING OIL PRESSURE

1. A special gauge is needed to check the oil pressure. It is attached to a fitting on the left side of the crankcase sump (see illustration).
2. Oil pressure should be checked when the engine is at operating temperature. Before checking, be sure that the oil level is between the two dipstick marks.
3. At 3,000 rpm, the oil pressure should be about 42 psi (3 kg/cm²).
4. If the pressure is significantly lower than this, remove and inspect the oil pump. If the oil pump condition is satisfactory, the lack of oil pressure may be caused by worn or damaged bearings.



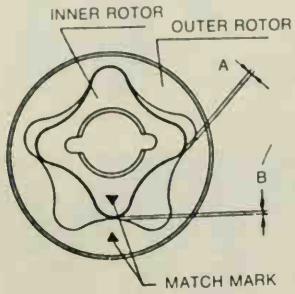
OIL PUMP

Removal



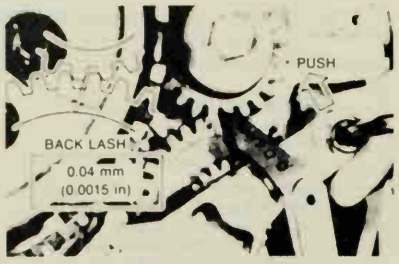
1. Drain the oil.
2. Remove the kickstarter pinch bolt and carefully pull the kickstarter off the splined shaft.
3. Remove the right-side footpeg and the rear brake pedal.
4. Remove the allen bolts which secure the right side crankcase cover and take off the cover. If the cover is stuck, tap around the sides with a plastic mallet to free it. Pull the cover straight off and do it carefully to avoid damage to the kickstarter shaft oil seal.
5. Remove the three allen bolts which hold the oil pump and pump gear and take off the assembly.

Inspection



1. Carefully loosen and remove the three phillips screws which secure the oil pump rotor cover plate. Remove the plate.
2. Measure the clearance between the rotor tips with a feeler gauge. The specified

Oil pump assembly allen bolts



Oil pump (1), cover screws (2), drive gear (3), and cover (4)

Rotor tip clearance (A,B) and rotor match marks

clearance is 0.03–0.09 mm (0.0012–0.0035 in.). If the measured clearance is not within this specification, replace the rotors.

Adjusting the gear backlash

3. Measure the clearance between the outer rotor and the oil pump housing. Specified clearance is 0.03–0.09 mm (0.0012–0.0035 in.). If the measured clearance exceeds this amount, replace the rotors or housing.

4. Lay a straight edge across the top of the rotors and measure the side clearance with a feeler gauge. Side clearance should be 0.010–0.18 mm (0.0039–0.0071 in.). If the measured clearance is greater than this, replace the rotors.

5. The rotors have match marks on one side. If the pump is disassembled, be sure that the rotors are installed so that the match marks line up.

6. Use a small amount of a non-permanent thread-locking compound on the oil pump rotor cover plate.

Installation

1. Installation is the reverse or removal. The primary gear-pump idler gear backlash must be adjusted.

2. Fit the oil pump assembly and install, but do not tighten, the mounting bolts. Measure the clearance between the primary gear and the oil pump idler gear. It should be 0.04 mm (0.0015 in.). To obtain the correct backlash push or pull on the oil pump assembly. When clearance is correct, hold the assembly in place and tighten the mounting bolts securely.

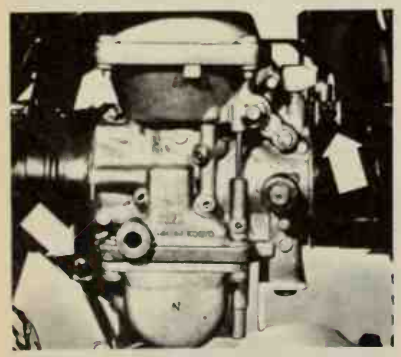
FUEL SYSTEM

CARBURETORS

Removal

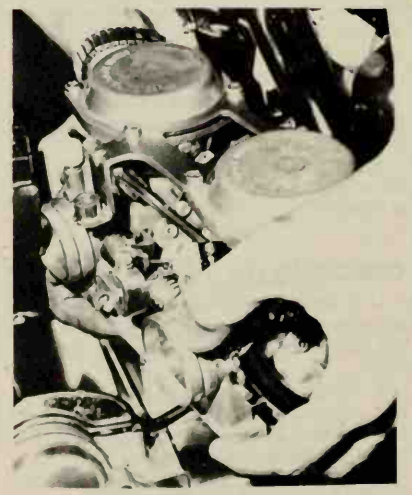


1. Disconnect the fuel line at the petcock. Disconnect the petcock vacuum line at the right manifold.

2. Lift the seat. Remove the gas tank bolt. Lift up the rear of the tank and slide it back until it is clear of its rubber mounts. Remove the gas tank from the motorcycle.

3. Disconnect the throttle cable from the lever between the carburetors.

4. Loosen the screws on the manifold clamps and the air cleaner hose clamps.



5. Carefully pull the carburetors back until they are free of the manifolds, then move them out to the side and off the motorcycle.

Installation

1. Installation is basically the reverse of removal.

Removing the drain plug

2. Position the carburetors on the manifolds and be sure they are properly seated. Work the air cleaner hoses around the carburetor mouths and be sure they are not folded are creased. Tighten the clamps. Connect the throttle cable. Check twist-grip action.

3. After fitting the gas tank and connecting the lines, turn the petcock to the "Prime" position for a few moments to fill the float bowls. Check for leaks before starting the motorcycle.

Disassembly

1. Remove the drain plug at the bottom of each float bowl. Holding the carburetors in the normal operational position, allow the gas to drain off. Refit the drain plugs to prevent loss.

2. Remove the angle-iron bracket which runs by the float bowls and holds the carburetors together.

3. Loosen the choke rod securing screws and disconnect the choke rod from the starter plungers. Pull out the rod. Take care that the shaft positioning balls on the left and right do not pop out.

4. Remove the bracket which holds the carburetors together at the caps.

5. Separate the two carburetors.

6. Remove the carburetor cap. Take out the return spring. Carefully, so as to avoid damage to the rubber diaphragm, lift out the throttle slide assembly.

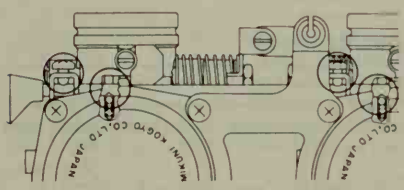
7. Remove the float bowl screws and carefully lift off the float bowl until it clears the floats. If the bowl is stuck, rap it once on the side with the screwdriver handle. This should be sufficient to break it free.

8. Using a small punch, push out the float pivot pin and remove the float bulbs.

9. Lift out the float needle.

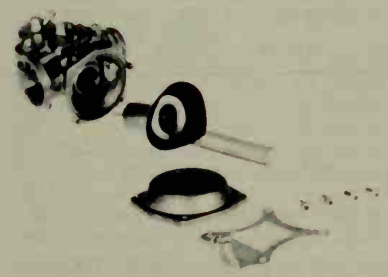
10. Unscrew and remove the float needle seat and gasket.

11. Unscrew and remove the pilot and main jets. On XS360 models, these are fitted to the float bowl, but on the 400 they are on the carburetor body. Jets are brass and should be removed carefully to avoid damage.



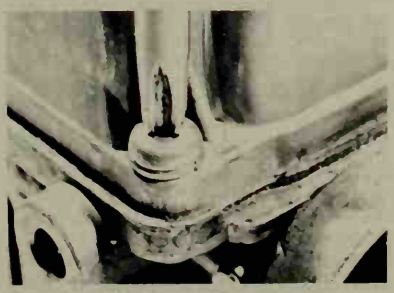
12. Pry out the washer beneath the needle jet, and remove this jet by tapping it out with a wooden dowel or the like from the top of the carburetor.

13. Remove the float bowl gasket.



14. Remove the banjo bolt for the fuel feed line from the left carburetor.

15. Remove the idle limiter caps from the pilot screws and remove the screws.



16. Unscrew and remove the starter plunger from the carburetor.

Inspection

1. Clean the carburetor body and float bowl in a carburetor cleaner or solvent which is safe for plastic parts and dry thoroughly.

2. Use compressed air to blow air and fuel passages clear.

3. Clean all fuel jets in the same manner.

CAUTION: *Do not insert anything into the jet passages to clear them; use air pressure only.*

4. Inspect the carburetor body for any vibration or stress cracks.

5. Check the condition of the throttle slide. Smooth movement of the slide on the carburetor body is imperative. If the slide sticks or binds at any point from full closed to wide open, replace it.

6. Inspect the needle jet and the needle. The needle must be free of nicks or score marks along its tapered portion. More often, however, these components will need to be replaced because of normal wear. As the throttle slide moves up and down while the machine is in operation, the needle is rubbing against the jet. Eventually, these components will wear enough to cause a noticeable rich running condition in the mid-throttle range. If this occurs, both the needle and the jet should be replaced. If the components are more than four years old, new ones should be fitted before attempting to tune the carburetor, or taking remedial action to correct a rich condition (such as lowering the needle).

7. Carefully inspect the float. Shake the float close to your ear; listen for any gasoline trapped inside. If the float assembly leaks, or if any puncture is noted, replace it; do not attempt repairs.

8. Inspect the tip of the float needle and the needle seat for dirt or corrosion. Check the needle tip for wear. If worn, the needle should be replaced.

If there is any corrosion or deposits evident on the needle or needle seat, the deposits must be removed, or the parts replaced.

NOTE: *Do not attempt to clean the needle or needle seat by lapping one against the other.*

To check the efficiency of the float needle valve, proceed as follows:

a. With the carburetor assembled except for the float bowl, connect it to its fuel line.

b. Place a number of dry rags beneath the carburetor, and hold it upright (in its normal operating position) with one hand.

c. With the other hand, gently raise the float assembly until the float needle is seated. Have an assistant turn the fuel petcock on ("Prime" position).

d. If the needle and seat are in good condition and forming a good seal, no gasoline will flow out of the carburetor.

e. If a leak is noted, replace the needle and seat.

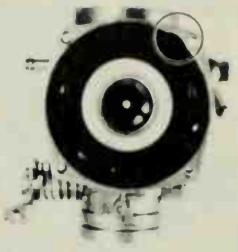
CAUTION: *While performing this test, be sure that adequate precautions are taken in the event of spillage.*

The float level should be checked prior to assembly.

9. Check that the tapered portion of the pilot screw is smooth and clean. Replace it if it is crushed or blunted.

10. Inspect the float bowl for a warped gasket surface, or stress cracks (especially around the screw holes).

11. Check the throttle slide diaphragm for rips. Replace the assembly if the diaphragm is damaged. Repairs are not possible.



Assembly

Assembly is basically the reverse of the disassembly procedure. Note the following points:

1. Always use new gaskets and O-rings.

2. Exercise care when installing jets—they are made of soft brass and are easily damaged if overtightened.

3. If the throttle slide and needle have been disassembled, check that both needle clips are installed in the correct groove from the top of the needle. Refer to the "Carburetor Specifications" chart at the end of this section for the correct needle clip position.

Be sure that the diaphragm tab is properly seated

4. When installing the pilot screws, turn them in gently until they are lightly seated, then back them out 1½ turns on XS360 models and 1¼ turns on XS400 models. Fit the idler limiter caps.

5. When fitting the throttle slide, be sure to engage the tab on the diaphragm with the cut-out in the carburetor body.

6. Check the float level as outlined in Chapter 3.

7. When installing the choke rod, be sure that the securing screws fit into the shaft detents.

FUEL PETCOCK

The petcock is the vacuum-activated type which incorporates a mesh filter inside the gas tank.

1. Set the petcock to the "RES" position. Disconnect the fuel line from the petcock and the vacuum line from the manifold.

2. Remove the gas tank. Drain off the fuel.

3. Unscrew the petcock securing nut or two phillips screws depending upon the method of fastening, and pull off the petcock.

4. Clean the filter screen in a solvent. Be sure to remove any foreign matter trapped in the screen as this will impede fuel flow. If the screen cannot be cleaned, or if it is punctured or otherwise damaged, it should be replaced.

5. Check the sealing washer and replace it if it is damaged.

6. Install the petcock. After the tank is refitted, check for leaks before operating the motorcycle.

7. Check operation of the petcock after disconnecting the fuel feed line. No fuel should flow out when the lever is in the "On" or "RES" positions. This should happen only when the lever is set to the "Prime" position. If fuel does flow in the other positions, replace the petcock.

8. In the event that fuel flow is a problem, check that the vacuum line is tightly secured at both ends, and is free from dry-rotting or other damage. Replace the vacuum line if any damage is noted.

ELECTRICAL SYSTEM

CHARGING SYSTEM

Alternator

OUTPUT CHECK

NOTE: *To give accurate results, the battery must be in good condition and fully charged before performing the output test.*

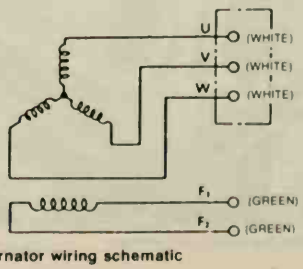
1. Connect a D.C. voltmeter across the battery terminals.

2. Start the engine and let it run at about 2,000 or more rpm.

3. Battery voltage on the meter should be 14.5 v with a maximum allowable variation of 0.3 v.

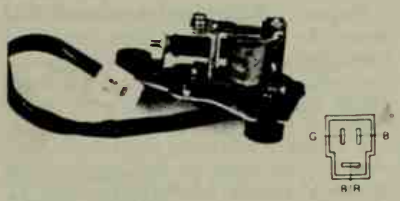
4. If the voltage is greater than this, check the voltage regulator (see below). If it is less, check the alternator wiring, the regulator, and the rectifier.

CAUTION: *Never run the engine with the battery leads disconnected. To do so risks ruining the other charging system components.*



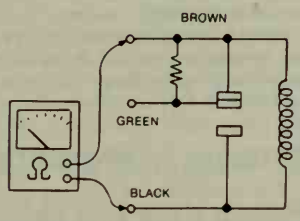
FIELD COIL/ARMATURE TESTS

1. With the engine *off*, disconnect the alternator wiring at the connector. With an ohmmeter, check the resistance between each of the three white leads. Resistance should be 0.72 ohms.



2. If the resistance is not within 10% of this value, the problem is probably with the alternator armature wiring. If the resistance is too high, the wiring is probably broken; if it is too low, the windings may be breaking down. In either event, the armature must be replaced.

3. Check the resistance across the two field coil leads (green-green). Resistance should be 4.0 ohms. If the measured resistance is not within 15% of this figure, replace the field coil.



NOTE: *Resistance figures are taken at 20° C (68° F). Therefore, it is preferable to*

Regulator

A mechanical voltage regulator is used on all models. The regulator is adjustable, although this procedure (given below) should not be attempted until the regulator has first been checked for defects.

1. Perform the alternator output test and field coil/armature tests first. If the alternator proves satisfactory, check the regulator.
2. Disconnect the wiring and remove the regulator from the motorcycle.
3. With an ohmmeter, check the resistance between the black regulator lead and the regulator base (black). Resistance should be 10.5 ohms. If the measured resistance is not within 2 ohms of this figure, replace the regulator.
4. Check the resistance between the green and the brown regulator leads. Resistance should be 140 ohms. If the measured resistance is not within 10 ohms of this figure, replace the regulator.
5. If the resistance tests indicate that the regulator winding and resistor are satisfactory, but the charging system is not developing the standard 14.5 v across the battery, the regulator may be in need of adjustment. However, it would be wise to check the rectifier first.
6. Remove the regulator cover. Install the unit on the motorcycle, checking that all wiring connections are correct.
7. Disconnect the fuse box wire leading to the battery. Connect a voltmeter from the fuse box to ground. Start the engine and allow it to run at 2,500 rpm. At this point, the voltmeter should read 14.5–15.0 v. If it does not, turn the regulator adjusting screw to obtain the correct voltage output. Turn the screw in to raise the voltage output, and *out* to lower it.

Rectifier

1. The rectifier consists of a six-diode "bridge." A diode will allow current to pass in one direction only. If any diode allows current to pass in both directions, or in neither direction, the operation of the entire unit will be upset and the rectifier will have to be replaced.
2. It is the ability of the diodes to pass current one way and stop it in the other which is tested when checking the rectifier.
3. The rectifier can be checked with an ohmmeter or a self-powered low-voltage test light. Disconnect the rectifier wiring and remove it from the motorcycle.
4. Connect the positive lead of the tester to the rectifier red lead and the negative tester lead to each of the three white leads in turn. Note whether or not there is continuity in each case. Now reverse the tester connections so that the negative tester lead is connected to the red rectifier lead and the positive tester lead is connected to each white lead in turn. Note whether or not there is continuity.

If there was continuity for a certain connection during the first test, there should not be any when the tester leads are reversed. If there was continuity in both cases, or lack of continuity in both cases, a diode is defective and the rectifier must be replaced.

5. Connect the positive lead of the tester to the rectifier black lead and the negative tester lead to each of the three white leads in turn. Repeat the test with these connections. Replace the rectifier if all tests are not satisfactory.

BREAKER POINT IGNITION

Troubleshooting

1. In the event of failure of the ignition system, first check the fuses; if all are in working order, check that the snap connectors for the coils and breaker points are all clean and tight.
2. At this point refer to chapters 2 and 3 for inspection procedures for the breaker points, plugs, and battery. If these items are all in working order, the problem may be isolated to the coils, condensers, or plug caps.
3. If only one cylinder fails to fire, and the problem is not a loose connection or defective spark plug, suspect the plug cap. The caps are fitted with a resistor to prevent radio interference while in operation, and heat and vibration may cause the value of this resistor to increase considerably, even to becoming an open circuit.

The easiest way to see if a misfire is due to a defective cap is to switch the plug cap of the non-firing cylinder with the other cap. If the dead cylinder begins to fire and the other cylinder ceases, the problem is the plug cap. The caps should be replaced as a set.

Functional caps will have a resistance of 9,000 ohms. Usually, when resistance exceeds this valve significantly, the plug for that cap will no longer fire.

Caps are easily removable by unscrewing them from their cables.

4. Defective condensers are seldom a problem, since these are now usually replaced along with the breaker points. Defective condensers will cause considerable arcing or sparking between the breaker point contacts while the machine is running, and this should be cause for replacement before they fail completely. Badly burned or pitted point contact surfaces can also be caused by defective condensers, as well as by improper adjustment. If the points are in bad condition, replace them and the condensers as well.
5. Condenser capacity can be checked with electrical test equipment (if available) in place on the machine, provided the condenser is first disconnected from the primary terminal. Capacitance should be 0.24 MFD. The resistance of the condensers should be in excess of 3 MΩ. A variation of 10% in either reading is allowable.
6. If the condensers are not suspect, check the ignition coils. Coils should be checked for continuity of the windings. First remove the gas tank. Disconnect the red/white coil lead and the other lead which is orange for the left cylinder's coil, or grey for the right. Check resistance across the leads. It should be about 4 ohms. If the resistance is not very close to this figure, the primary winding is defective and the coil must be replaced.
7. To check the secondary coil, first remove the spark plug cap from the plug lead. Check the resistance between the plug lead and the orange or grey lead. Secondary winding resistance should be 9.5 K ohms. If the measured resistance is not very close to this value, the secondary winding is breaking down, and the coil must be replaced.

TRANSISTORIZED IGNITION

Troubleshooting

1. In the event of spark failure, first check the entire electrical system for loose connections.
2. Check that the battery is fully charged. Recharge if necessary.
3. Check all fuses.
4. If all of the above elements are found satisfactory, check the resistance of the ignition coil primary and secondary windings. Primary winding resistance should be about 3 ohms. Secondary resistance should be about 8.6 K ohms.

The primary winding leads at the coils are red/white and orange. The secondary winding resistance is checked between the spark plug lead (minus cap) and the re/white lead.

5. Check the pick-up coils' resistance. It should be about 700 plus/minus 150 ohms.
6. If all of the above elements are satisfactory, replace the TCI unit.

Pick-up Coil

REMOVAL AND INSTALLATION

The pick-up coils are located beneath the cover on the left side of the cylinder head.

1. Centerpunch the blind plug which secures the cover. Use a 5 mm drill bit to drill the plug.
2. Cut internal threads 6 mm diameter x 1.0 mm pitch in the blind plug with a proper sized tap. Thread in the special slide hammer, or a suitable metric bolt, and pull out the plug.
3. Remove the cover screws and take off the cover.
4. Remove the rotor bolt and rotor.
5. Remove the pick-up coil screws and take off the assembly.
6. Installation is the reverse of removal. Install the rotor and tighten the rotor bolt to 7 ft lbs. Check the ignition timing as outlined in "Tune-Up." Rotate the pick-up coil base plate, if necessary, until the timing marks align as specified. After fitting the pick-up coil cover, install a new blind plug. Do not

force the plug in if it is too tight, as this may crack the cover.

STARTING SYSTEM

The starting system consists of the starter motor and clutch, the solenoid, and the handlebar-mounted starter switch. When the button is pressed, the electrical circuit to the solenoid is closed and the solenoid is activated, sending the battery current directly to the starter motor. The starting system is quite reliable and it is unlikely that any major problems will arise.

Testing

If the starter will not operate, switch on the headlight and observe its intensity. If it is dim when the starter is not being operated, check the battery connections and recharge the battery. If the headlight doesn't light, check the fuse, the battery connections, the ignition switch and its connections, and check the continuity of the wire between the ignition switch and the battery.

If the headlight is normally bright, press the starter button and observe any changes. If the headlight dims when the button is pushed, it indicates that the starter motor is drawing current. If it does not dim (i.e. nothing happens), the starter motor is probably not getting any current. In this case, suspect the starter solenoid.

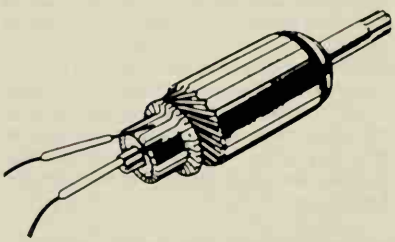
To check the solenoid and starter button, the easiest test is to bypass the unit completely by disconnecting the battery lead from the solenoid and connecting it directly (with the aid of a high-tension jumper cable) to the starter motor terminal. If the starter motor works, the solenoid or starter button is defective and must be replaced.

If the motor still fails to work, the motor itself may be the cause of the trouble.

Starter motor faults are rare, but several things can go wrong.

If the starter spins freely, but the engine doesn't turn over, suspect the starter motor clutch.

If the engine will turn over only very slowly and without a great degree of predictability, some possible causes include: a low or almost dead battery, oil which is too thick for weather conditions (extreme cold), or bad bearings in the motor itself. Worn bearings could cause the armature to contact the field coils which will effectively short out the starter. Usually, repeated attempts at starting will result in the starter motor getting very hot. Other possible causes of starter motor trouble include worn brushes, a worn or dirty commutator, or a defective armature.



Starter Motor Service

REMOVAL AND INSTALLATION

1. Remove the gas tank. Remove the carburetors.
2. Remove the starter motor cover. Disconnect the starter lead.
3. Remove the alternator cover.
4. Remove the starter motor bolts.
5. Remove the gear from the starter motor shaft and take out the starter motor.
6. Installation is the reverse of removal.

INSPECTION

1. Take out the two screws and remove the starter side cover.
2. Check electrical continuity between the commutator and armature core using a multitester or test light and battery. If continuity exists, the armature coil is grounded and the complete starter motor unit must be replaced.
3. Check for continuity between all of the commutator segments. Continuity must exist in each case.
4. Check continuity between the brush that is wired to the stator coil and the starter motor cable. Lack of continuity indicates an open circuit in the stator coil, and the starter motor unit should be replaced. Resistance should not exceed 0.05 ohms.
5. Examine the carbon brushes for damage to the contact surfaces and measure their length. Replace the brushes as a set if either one measures less than 6 mm (0.24 in.), or if they are damaged in any way.

Checking for continuity between commutator segments

6. Brush spring tension should be measured with a small pull-scale. Replace the springs if they have weakened to less than 550 g tension.
7. The mica undercut of the commutator should be maintained at 0.7 mm (0.027 in.). Any carbon deposits should be cleaned out of the commutator grooves, and a piece of hacksaw blade or the like used to increase the undercut depth if necessary.
8. Polish the commutator with fine emery cloth and then clean it thoroughly before installing.
9. Measure the diameter of the commutator. The armature should be replaced if the measurement is less than 27 mm (1.06 in.).
10. Check the condition of the armature bearings and replace them as a set if any damage is noted.
11. Check the condition of the oil seal and replace it if the seal lips are cracked or worn.
12. Unsealed bearings should be lubricated with 20W or 30W motor oil before assembly. Coat the lips of the oil seal with white grease before assembly.

Starter Solenoid

1. If the battery is in reasonably good condition, and nothing at all happens when the starter button is pushed, check the solenoid.
2. Disconnect the starter cable at the solenoid. When the button is pushed, there should be an audible "click" which indicates that the solenoid is opening.
3. If further testing is necessary, remove the solenoid from the machine.

CAUTION: *Be sure to disconnect the cables at the battery before disconnecting the solenoid terminals.*

Connect a fully charged 12-volt battery across the solenoid low-tension leads and check for continuity across the high-tension terminals with an ohmmeter or self-contained test light. If there is no continuity, replace or repair the solenoid.

4. Check for continuity across the low-tension terminals with an ohmmeter or self-powered test light. Resistance should be 3.5 ohms. If there is no continuity, the primary winding of the solenoid is broken, and the unit must be replaced.
5. If starter trouble began just after the starter button housing was disassembled or moved for any reason, check the connections at the switch as they may have come adrift.

ELECTRICAL COMPONENTS

Horn

1. If the horn fails to sound, check that there is 12 v on the brown horn lead. If there isn't, check for a broken wire.
2. If the brown lead checks out, check that the pink wire is grounded when the horn button is pressed. If it isn't, check the horn button.
3. If the wiring is satisfactory, replace the horn.

Brake Light

1. If only one of the two brakes fails to activate the brake light, the problem is probably confined to that switch.
2. If neither switch will activate the brake light, first check the brake light bulb. If it is in workable condition, check that there is 12 v on the yellow brake light lead.
3. If there is voltage on the yellow lead, check for voltage on each brown lead at the brake light switches.

Taillight

1. If the taillight will not work, check the bulb first.
2. If it is satisfactory, check for voltage on the blue lead. If there is voltage on this wire, check for a good ground (black wire).

Turn Signals

1. If only one side fails to work, check both bulbs on that side first.
2. If the bulbs are operable, check for voltage on the green (right) or brown (left) leads. If there is voltage here, check the grounds (black leads).
3. If neither side will work, check for voltage on the brown/white lead at the handlebar turn signal switch. Then check for voltage on the brown lead at the turn signal flasher relay.
4. If these checks are satisfactory, replace the flasher relay. If the turn signals still will not operate, replace the flasher switch. If this will not work, the entire self-cancelling system must be checked out (see below).

Neutral Indicator

1. If indicator light fails to come on, check the bulb first.
2. If the bulb is satisfactory, check that there is voltage on the blue wire at the switch. If there is, replace the switch itself.

Oil Pressure Indicator

1. Check the bulb first.
2. If the bulb is satisfactory, check for voltage on the black/red lead to the switch.
3. If the wiring checks out, replace the oil pressure indicator switch.

Self-Cancelling Turn Signal System

1. In the event that the self-cancelling system fails to operate properly, first disconnect the 6-prong connector from the flasher cancelling unit and try the turn signals. If both sides operate normally, the trouble can be confined to the cancelling unit itself, the handlebar switch reset circuit, or the speedometer sensor circuit.
2. Connect an ohmmeter set to the R x 100 range across the white/green and black wires on the wiring harness side of the 6-prong connector. Turn the speedometer shaft. The ohmmeter needle should swing back and forth between zero and infinity four times. If this happens, it indicates that the speedometer sensor circuit is functioning properly. If the meter does not function in this manner, either the sensor or the wiring harness is defective.
3. Check for continuity between the yellow/red lead of the 6-prong connector on the wiring harness side and ground on the chassis. When the turn signal switch is *off*, there should be infinite resistance. When the switch is pushed to either "L" or "R", there should be no resistance. If this is not the case, check the wiring harness and the handlebar switch circuit.
4. If no defective operation is apparent in the above tests, replace the self-cancelling unit.
5. If the turn signals operate only when the turn signal button is pushed to "L" or "R" and they shut off immediately when the button is released, replace the self-cancelling unit.

Note the following concerning the self-cancelling turn signal system:

a. Yamaha recommends that the turn signals be shut off manually after a turn is completed.

b. If the self-cancelling unit fails, the turn signals can be used manually by simply disconnecting the 6-prong connector from the unit.

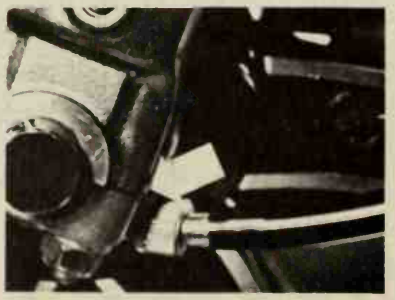
CHASSIS

WHEELS

Front Wheel Assembly

REMOVAL AND INSTALLATION

1. Support the front wheel several inches off the ground by placing a support beneath the engine.
2. On drum brake models, disconnect the brake cable at the handlebar.
3. Disconnect the speedometer cable at the wheel.
4. Remove the axle nut cotter pin and remove the axle nut.
5. Loosen the axle cap nuts. Pull out the axle and remove the wheel from the machine.
6. On disc brake models, place a piece of cardboard or the like between the brake pads to keep them apart.
7. Installation is basically the reverse of removal. Note the following points:



a. Grease the lips of the wheel grease seals and the speedometer drive mechanism with white grease.

b. On drum brake models, be sure to engage the brake anchor with the slot on the fork slider. On disc brake models, be careful when fitting the wheel so that the brake disc is properly installed between the pads.

c. If the axle cap has been removed, install it so that the arrow on it points towards the front of the motorcycle.

d. When tightening the axle cap nuts, tighten the frontmost one first. Torque it to 15 ft lbs. Then tighten the rear one to the same torque. The cap is machined unevenly. There should be a small gap between the cap and the fork slider visible above the rearmost nut.

e. Tighten the axle nut to 72 ft lbs on drum brake models and 77 ft lbs on disc brake machines. Use a new cotter pin.

Tighten the forwardmost axle cap nut first: there should be a gap between the cap and the slider at the rear (arrow)

f. Check brake operation *before* riding the motorcycle.

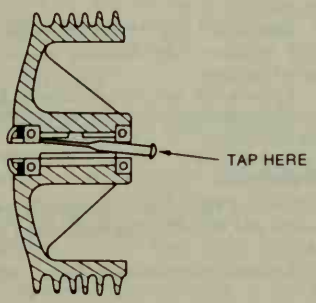
WHEEL BEARINGS

Removal

1. After removing the front wheel, remove the brake plate on drum brake models, or the brake disc on disc brake machines.
2. Remove the speedometer drive box on disc brake machines.
3. Remove any wheel bearing covers or retainers fitted to either side of the hub.
4. Pry out the grease seals. Once removed, the seals should be replaced with new ones.
5. Reach through the hub with a suitable punch, move the wheel bearing spacer as far as possible to one side to achieve a purchase on the wheel bearing, and drive it out. Remove the spacer. Drive out the remaining wheel bearing from the other side of the hub.

Inspection

1. Wash the wheel bearings thoroughly in a solvent to remove all of the old grease.
2. Inspect the general condition of the bearings. There should be no rust, pitting, or obvious signs of wear or damage on either balls or races.
3. Slowly rotate the bearings. Rotation



should be smooth, noiseless, and free of binding or unevenness. If any of the above conditions exist, both bearings should be replaced.

4. Place each bearing on a flat surface and hold the inner race firmly in place. Attempt to move the outer race up and down. If any play is evident, the bearings should be replaced.

5. If equipment is available, a dial gauge can be used to check bearing run-out. Pass the axle through each bearing in turn and check the axial and diametrical run-out with the gauge. If axial run-out exceeds 0.1 mm (0.004 in.) or if diametrical run-out is greater than 0.05 mm (0.002 in.), the bearings should be replaced.

To check diametrical run-out, the dial indicator is placed directly on top of the outer race and the race moved up and down.

To check axial run-out, the gauge is positioned to bear against the side of the outer race and the race moved back and forth while holding the inner race in place.

Removing a wheel bearing

Installation

Assembly is the reverse of the above.

Note the following points:

a. Pack the bearings with a good grade of wheel bearing grease. Put a small handful of the grease in the hub as well.

b. Do not forget to install the spacer in the hub before installing the bearing.

c. Bearings may be driven into place using a suitably sized socket or a bearing driver. If one side of the bearing is sealed, install it with the sealed side facing outward.

d. Use new grease seals and lubricate them with oil to make installation easier.

Rear Wheel Assembly

REMOVAL AND INSTALLATION

Rear Drum Brake

1. Park the motorcycle on the center stand.

2. Remove the brake rod adjusting nut and disconnect the brake rod from the lever on the brake plate.

3. Disconnect the brake anchor from the brake plate.

4. Remove the cotter pin and loosen the axle nut. Loosen the chain adjuster bolt locknuts. Back off the adjuster bolts.

5. On models with a masterlink chain, disconnect the chain. On models with an endless chain, fold down the adjuster plates and push the wheel as far forward as possible. Disengage the chain from the sprocket.

6. Remove the axle nut and pull out the axle. Remove the wheel from the motorcycle, noting the locations of any spacers or collars.

7. Installation is the reverse of removal. After adjusting the chain tension, tighten the axle nut to 50–72 ft lbs. Use a new cotter pin.

Rear Disc Brake

1. A special tool is needed to remove the rear wheel. This tool, a length of wire with hooks to support the rear wheel, is supplied in the tool kit.

2. With the machine on the side stand, attach one end of the tool to the frame hook. Compress the shocks as much as possible and hook the other end of the tool to the swing arm. Place the machine on the center stand.

3. Disconnect the drive chain.

4. Remove the axle nut cotter pin and unscrew and remove the axle nut.

5. Hold the brake caliper in position so it will not fall out of place, and pull out the axle. Remove the rear wheel assembly.

NOTE: *Do not apply the brake while the wheel is off the machine.*

6. Installation is the reverse of removal. Before fitting the wheel, check that there is sufficient clearance between the brake pads to install the disc. Grease the lips of the wheel bearing grease seals. Tighten the axle nut to 77 ft lbs.

WHEEL BEARINGS

Removal, inspection, and installation of the wheel bearings is accomplished in basically the same manner as for the front wheel described above.

TUBELESS TIRES

Precautions

Some models are equipped with aluminum wheels which are compatible with either tube or tubeless tires. Tubeless tires are installed at the factory. Obey the following precautions when dealing with tubeless tires.

1. Do not attempt to use tubeless tires on wheels which are not specifically designed for them.

WARNING: *Injury or tire failure may result from using tubeless tires with incompatible wheels.*

2. Tire pressure is critical. Always maintain pressure at the proper specification.

3. Check tire condition before riding.

4. Aluminum wheels cannot be repaired. If the wheel is bent or cracked, it must be replaced.

5. After changing or fitting a new tire, ride with caution for several miles to allow the tire to seat itself properly on the wheel.

6. Be sure that the valve stem locknut is securely fastened.

7. Changing a tubeless tire is basically the same as described for the tube type described above. Refer to that section for procedures.

8. The tubeless wheels fitted to the XS400SG will accept a tube and tube type tire if so desired. Be sure, however, that the tube is the proper size for the tire.

9. Do not attempt to fit oversized (wider) tires to the standard wheels.

DISC BRAKE SERVICE

When handling disc brake fluid, observe the following precautions:

a. Use DOT #3 brake fluid only. Do not mix types or brands of brake fluid. Since the fluid in the motorcycle may be incompatable with the fluid you wish to add, it is wise to flush the entire system and refill it with the new fluid. The brake system should be flushed and refilled with fresh brake fluid about every two years in any case.

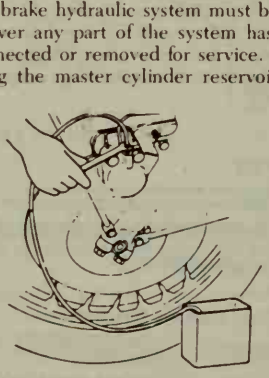
b. Never use brake fluid from an old or unsealed container. Brake fluid is hydroscopic: it absorbs moisture. Therefore, brake fluid left in a container which is not tightly sealed will quickly become useless.

c. When working on the disc brake system, be sure that all components are scrupulously clean. Clean the tops of brake fluid cans, the master cylinder reservoir, etc., before removing their caps. Be sure hands and tools are free of foreign matter and that rags are at least reasonably dirt-free.

d. Brake fluid will remove paint in short order. Be sure that all painted surfaces which can come in contact with the brake fluid through spillage or other accidents are well covered. This includes items such as the gas tank and frame.

FLUSHING

The brake system should be flushed out every 12,000 miles, or every 2 years.



1. Attach a length of vinyl tube to the bleed valve on the brake caliper and put the other end into a small container.

2. Remove the master cylinder cap, and the diaphragm. Loosen the bleed valve about ½ turn. Pull the brake lever slowly to the handgrip, then tighten the bleed valve. Release the lever. Repeat until the master cylinder is almost empty.

3. Add new brake fluid to the master cylinder and continue squeezing and releasing the brake lever slowly until the new fluid begins to come out of the vinyl tube. Bleed the system as outlined below.

BLEEDING

The brake hydraulic system must be bled whenever any part of the system has been disconnected or removed for service. When refilling the master cylinder reservoir, use

Bleeding the brake system

only brake fluid conforming to DOT 3 specifications. Any brand meeting this requirement is acceptable. The brake fluid container of all reputable brands will be plainly marked with the standards the fluid meets or exceeds.

NOTE: *It is sometimes helpful to let the cycle sit for several hours before bleeding the system. Pulling and tapping on the lines will help expel any air bubbles trapped in the system. If you find that you can't get the system bled properly and the*

master cylinder has been dry for awhile, the seals inside the cylinder may have become dried and cracked. In this case rebuild the master cylinder.

1. Top up the reservoir with brake fluid and replace the cap to keep dirt and moisture out and the fluid in. Cover the gas tank with a thick cloth to avoid damage due to spilled brake fluid.
2. Attach one end of a small diameter rubber hose to the bleed valve on the caliper, and place the other end in a jar which contains several inches of clean, new brake fluid. Be sure that the end of the hose is submerged in this fluid. Arrange the hose so that it loops upward after leaving the bleed valve, and see that it has no kinks or sharp bends.
3. Pump the brake lever rapidly several times until some resistance is felt and, holding the lever against the resistance, open the bleed valve about one-half turn. When the lever bottoms, close the valve (do not overtighten) and then release the lever.
4. Repeat the operation until no more air is released out of the hose and the brake lever is firm in operation. Check the fluid level in the reservoir often to make sure that it doesn't go dry and draw more air into the system. Do not reuse fluid that has been pumped out of the system. Do not use fluid that has been stored for more than a few weeks after the seal on its container has been opened, as brake fluid will absorb moisture from the air and may corrode the master cylinder and caliper.
5. Refill the reservoir to the level mark when through (but do not overfill). Avoid overtightening the cap or fluid will weep around the cap edge.

Front Disc Brake

PAD REPLACEMENT

1. Unbolt the caliper from the fork slider.
2. Remove the pad screw which secures the fixed pad on the wheel side of the caliper. Remove the fixed pad.
3. Remove the piston pad.
4. Installation is the reverse of removal. Secure the fixed pad phillips screw with a non-permanent thread-locking compound.

CALIPER

Removal

1. Disconnect the brake line from the caliper. Plug the end of the brake line to prevent loss of brake fluid.
2. Remove the mounting bolts and take the caliper from the fork slider.

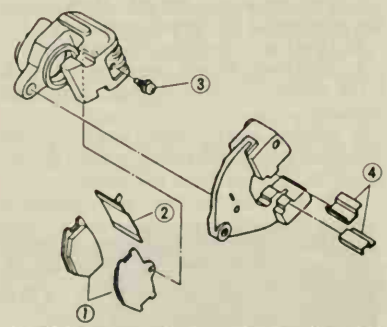
Disassembly

1. Remove the phillips screw which secures the fixed pad and take out the pad and pad spring.
2. Remove the piston pad.
3. Remove the caliper support bolt. Separate the caliper and support bracket. Remove the piston dust seal and retaining ring.
4. Apply compressed air to the brake line fitting on the caliper and force out the piston.

Caution: Be sure your fingers are clear of the piston, as it may come out with some force.

5. Remove the piston seal.

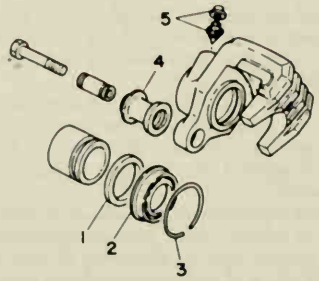
Inspection



1. Clean all parts in new brake fluid. Do not use gasoline or other solvents.
2. All rubber parts should be replaced with new ones once the caliper has been disassembled. These parts should also be replaced every two years as a matter of preventive maintenance.
3. Check the piston for scoring or other obvious signs of wear, and replace it if damage is noted. Check the caliper bore as well.

Assembly

1. Using a new caliper support bolt is recommended. As noted above, all rubber parts must be replaced as well.
2. Lightly lubricate the piston seal with fresh brake fluid and install it in the caliper. Be sure that the seal is properly seated.
3. Lubricate the sides of the piston with brake fluid and install it.
4. Fit the caliper and support bracket together, not forgetting the bushing and bushing boot. Install the support bolt and tighten it to 11–15 ft lbs.
5. Install the brake pads. Secure the fixed pad phillips screw with a non-permanent thread-locking compound. Grease the pad-shim contact area before installation. Bend each tab of the shim over the piston pad.



Caliper mounting bolts

Caliper pad components: 1, pads; 2, pad spring; 3, screw; 4, retainers

Installation

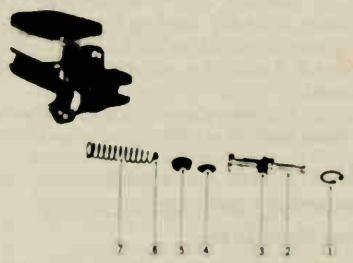
1. Tighten the caliper mounting bolts to 21–29 ft lbs.

Caliper components: 1, piston seal; 2, boot; 3, dust cover clip; 4, bushing boot; 5, bleed screw

2. Tighten the brake line banjo bolt to 18–25 ft lbs. Bleed the system.

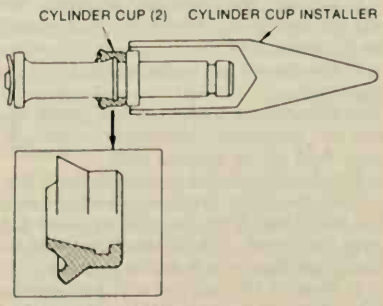
MASTER CYLINDER

Removal



1. Disconnect the front brake light switch leads.
2. Remove the brake lever. Note the return spring.
3. Disconnect the brake line from the master cylinder. Take adequate precautions to avoid spillage.
4. Remove the two master cylinder handlebar clamp bolts and remove the master cylinder assembly.

Disassembly



1. Remove the master cylinder cap and diaphragm and drain off and disgard the brake fluid.
2. Remove the master cylinder rubber boot.
3. Remove the snap-ring. Take out the piston assembly. The spring will remain in the master cylinder.
4. Remove the spring and stopper valve.
5. Remove the stopper plate and the cylinder cups.

Inspection

1. Clean all parts in fresh brake fluid.
2. Check the master cylinder port for clogging.

Master cylinder components

Installing the cylinder cup

3. Check the piston and cylinder bore for scoring and wear and replace the components if damage of this sort is noted.

4. Check the cylinder cups for cracking and dry-rotting and replace them if this condition is present.

Assembly

1. Soak the cups in new brake fluid for a time before assembly.

2. Use the special cylinder cup installer when fitting the cup to the piston.

3. Install the stopper plate into the master cylinder. Insert the spring and valve.

4. Insert the piston into the master cylinder. Take care not to scratch the piston or cylinder wall. Fit the snap-ring. Be sure that it is firmly seated.

5. Fit the boot into the grooves of the master cylinder and piston.

Installation

Bolt the master cylinder to the haldlebar. Connect the brake and tighten the banjo bolt to 17–20 ft lbs. Fill the master cylinder with fresh brake fluid and bleed the system.

DISC SERVICE

The brake disc normally requires no service of any kind. However, if the disc becomes scored for any reason, it should be replaced and a new set of pads should be installed. A badly scored disc will reduce the effectiveness of the brake and shorten pad life considerably. If the front brake lever oscillates or fluctuates when the brake is applied at speed, the indication is that the brake disc is warped or bent. Check the run-out of the disc with a dial indicator and replace it if run-out exceeds 0.15 mm (0.006 in.). Measure disc thickness. If it is less than 4.5 mm (0.18 in.), it should be replaced. To replace the disc:

1. Remove the wheel.

2. Bend back the locktabs, unscrew the bolts, and remove the disc from the hub.

3. Mount the new disc on the hub and tighten the bolts evenly, using new locktabs or thread-locking compound to secure them. Proper torque is 12–16 ft lbs.

4. Examine the brake pads and replace them if they are close to the limit of wear or have worn in an unusual pattern.

Rear Disc Brake

The rear disc brake components are virtually identical to those for the front system except for the method of mounting.

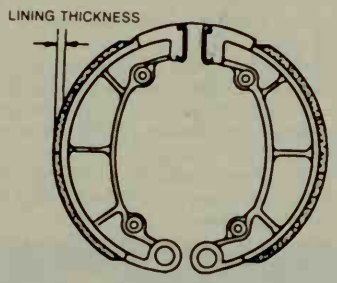
To remove the rear caliper, disconnect the brake line from the caliper, unbolt the brake anchor, and remove the rear axle.

For all service procedures, refer to the "Front Disc Brake" section above.

Front Drum Brake

1. Remove the front wheel from the machine. Take out the brake plate.

2. Check the linings for scoring, a glazed surface, or other unusual wear. Scored linings should be replaced. If the linings are only glazed, they can be roughed up with sandpaper. Be sure to clean them thoroughly after this operation.



3. Measure lining thickness at the middle and ends of each brake shoe. Minimum acceptable lining thickness is 2 mm (0.08 in.). New linings will have a thickness of 4 mm (0.16 in.).

4. Remove the shoes from the brake plate by folding them in towards the center.

5. Check the condition of the brake return springs. Standard free length of the springs is 68 mm (2.68 in.), and they should be replaced if they are stretched over this standard. Also check the springs for rust, damaged ends, or other obvious signs of age.

6. Measure the diameter of the brake drum in at least two directions. Standard diameter is 180 mm (7.1 in.). If the measured diameter exceeds this standard by more than a small amount, the drum should be replaced.

7. Rough up the surface of the brake drum

with sandpaper. Clean the drum out thoroughly before assembly.

8. Check for excessive play in the brake rod linkage. If play exists, the most obvious cause is wear wear of the clevis pins. Replace the pins as necessary.

9. The brake cams can be removed from the brake plate after removing the shoes and brake linkage. Mark the brake levers and cams before disassembly so the levers can be reinstalled in their original positions. Clean the cams in solvent. Remove any rust or corrosion with medium grade emery cloth. Check that the cams can rotate freely in their holes. Check the condition of the splines. Replace any bent or otherwise damaged cams. Before installation, smear the cams with a good grade of chassis grease.

Rear Drum Brake

Service procedures for the rear drum single-leading shoe brake are similar to those for the front drum brake described above. The only difference is the brake drum diameter which is 160 mm (6.3 in.) for the rear brake.

FRONT FORKS

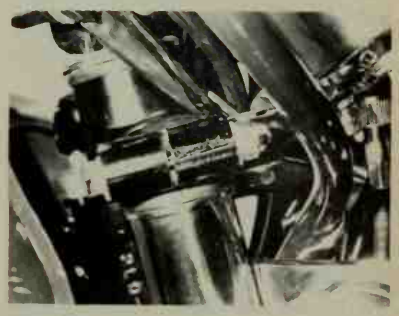
Removal

1. Remove the front wheel and fender.

2. On disc brake models, unbolt the caliper from the fork slider. Disconnect the brake line from the fork leg.

3. Loosen the upper and lower triple clamp pinch bolts. Pull each fork leg down and free of the triple clamps.

Dissassembly



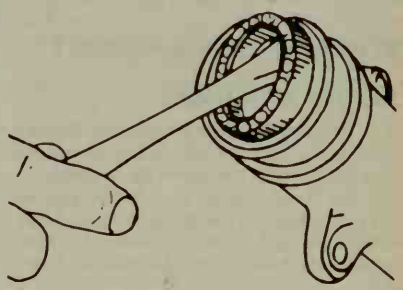
1. Remove the rubber fork caps, press down on the metal caps and remove the snap-ring. Take out the cap and fork spring. Drain off the fork oil.

2. Remove the allen bolt from the bottom of the fork slider.

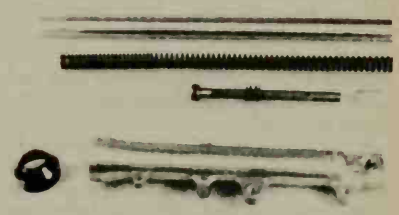
3. Separate the fork slider from the fork tube.

4. Remove the clip from the bottom of the fork tube and remove the piston assembly.

5. To remove the slider oil seal, remove the dust cover and the snap-ring and pry the old seal out. New seals must always be used on assembly.



Upper triple clamp pinch bolts



Inspection

1. Inspect the fork tubs for bends such as might have been incurred in an accident. Replacement is recommended rather than attempting to straighten bend fork tubes.

2. The chrome plating on the fork tubes must be in perfect condition in the area along which the slider oil seal rides. If the plating is chipped or flaking, the seal will leak. Damage to the plating requires replacement of the fork tube.

Removing a fork slider oil seal

Fork components

3. Compare the spring heights of the fork springs from each fork leg. They should be equal. Standard spring free length is 484 mm (19.1 in.). If the spring heights are unequal, or if either or both of them has been compressed through use, both should be replaced.

4. Clean the damper components thoroughly in a safe solvent. Be sure that all bleed holes are clear. Clean out the inside of the fork sliders with solvent as well.

Assembly

Assembly is the reverse of disassembly. Note the following points:

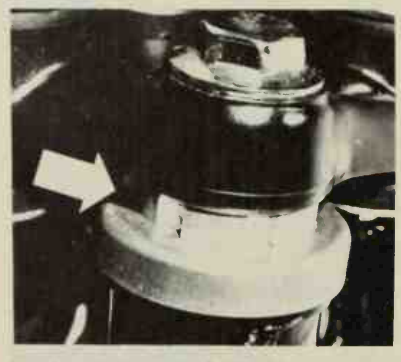
a. New slider oil seals must always be used. Drive the new seals straight into the slider (sealed side up) until there is sufficient room to install the snap-ring in its groove. Use a large socket or the like to install the seal. Be sure it is not cocked or twisted during the installation procedure. Install the snap-ring. Oil the lips of the seal before assembling the fork components.

b. Tighten the fork slider allen bolt securely. The threads of the allen bolt should be coated with a non-permanent thread-locking compound before installation.

c. The fork springs are progressively wound. They are installed so that the close coils are towards the *top*.

Installation

1. Fit each fork leg up through the triple clamps until the top edge of the fork tube is flush with the upper surface of the upper triple clamp.
2. Tighten the lower triple clamp pinch bolts to 22–29 ft lbs.
3. Tighten the upper triple clamp pinch bolts to 7–10 ft lbs.
4. Fill each fork leg with 130 cc (4.4 oz) of the proper fork oil. Refer to the "Maintenance" chapter (chapter 2) for oil recommendations.
5. Install the front wheel and fender and caliper assembly, if applicable.



STEERING STEM ASSEMBLY

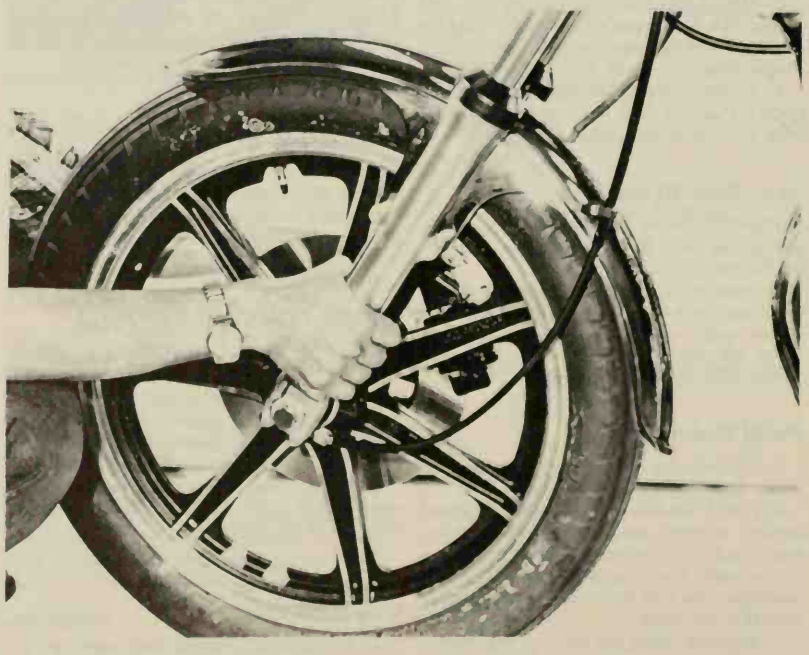
Bearing Adjustment

1. The steering stem bearings are uncaged ¼-in. balls. They are adjusted by means of a ring nut beneath the upper triple clamp.
2. To check bearing adjustment, support the front wheel off the ground. Grasp the tip of the front fender and place your other hand beneath the lower triple clamp at the frame lug.
3. Attempt to move the fork by pulling up on the tip of the fender. If play or movement can be felt at the lower triple clamp, the bearings are adjusted too loosely or are worn. An alternate method is to grasp the fork sliders and attempt to move them back and forth in line with the motorcycle. No play should be noted.
4. Turn the forks slowly from lock-to-lock. Movement should be smooth, silent, and effortless. If any binding or uneven movement is felt, the balls and races are either too tightly adjusted or they are worn. If the steering feels uniformly stiff, the bearings are too tightly adjusted. If any noise is noted, the bearings are damaged or some are missing.
5. With the front wheel off the ground, release the front forks from a few degrees off the centered position. The fork should fall freely to either side of their own weight. If they will not, the bearings are too tightly adjusted, the steering stem is bent, the races are extremely worn, or some of the bearings are missing.
6. To adjust the bearings, remove the gas tank. The bearings are adjusted by means of the adjuster nut under the upper triple clamp.
7. Tighten or loosen the adjuster nut a little at a time until the steering stem adjustment conforms to that outlined above.
8. If proper adjustment is not possible, the bearings and races will probably need to be replaced.

Disassembly

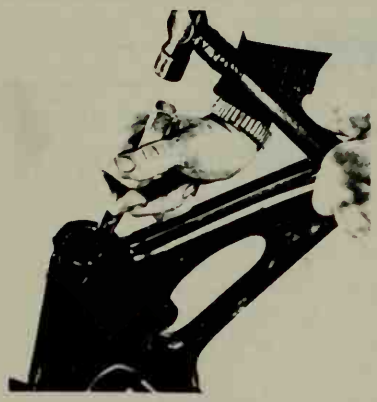
1. Remove the front wheel, front fender, and the fork legs.
2. Remove the headlight bracket.
3. Remove the gas tank. Disconnect the headlight wires beneath the tank.
4. Disconnect the wires between the handlebar switches and the main wiring harness.
5. Disconnect the clutch and throttle cables at the handlebars and the instrument cables at the instruments. On disc brake models, unbolt the master cylinder from the handlebar.
6. Loosen the steering stem pinch bolt. Remove the upper triple clamp fitting bolt and crown washer.

Steering head bearing adjuster nut



7. Remove the upper triple clamp complete with instruments.
8. Hold the lower triple clamp in place to prevent the lower race balls from falling out, and unscrew and remove the bearing adjuster nut. Remove the bearing cover.
9. Carefully lower the lower triple clamp/steering stem assembly out of the frame lug. Note that the lower race balls may fall out as the assembly is lowered.
10. Remove the top bearing cover and race and remove the ball bearings.
11. Remove the bottom cone race, dust seal, and dust seal washer from the steering stem if they are to be replaced. These will have to be pried off with a chisel, therefore only remove them if necessary.
12. The bearing races in the frame lug are a press-fit and should not be removed unless replacement is necessary. If replacement is necessary, the old races can be removed by reaching through the frame lug with a suitable punch and tapping the race evenly around its circumference to remove it from the inside of the frame lug. Be sure that the race does not become cocked in its seat upon removal.

New races are installed with a suitably sized bearing driver, i.e., one which will drive the race squarely into its seat. Be certain that the race goes straight in.



These races can also be installed using a block of hard wood of sufficient size to cover the race in place of a bearing driver.

Inspection

1. Wash the ball bearings in a suitable solvent.
2. Clean all of the old grease from the bearing race surfaces, steering stem, and frame lug.
3. Inspect the bearing race surfaces. They must be clean and smooth and free of any cracks, scoring, rust, or indentations. Run your finger around each of the bearing races.

Checking steering head bearing play

Removing the frame races

Note any roughness or ripples on the race surface. If any imperfections are noted, both sets of races and all of the balls must be replaced.

4. Check the balls themselves for rust, pitting, scoring, or flat spots. If the balls are found to be defective in any way, the balls and both sets of races must be replaced.

NOTE: *Balls and races must always be replaced in a set because worn races will destroy new balls and worn balls will destroy new races.*

5. Check the dust seal for condition and replace if torn or cracked.

6. Check the steering stem for cracks or a bent condition; this is especially important if the bike has been involved in a spill.

Assembly

1. Put a coat of a good grade of bearing grease on the steering stem race and the upper frame race.

2. Imbed the ball bearings in the grease. There are 19 balls in each race.

3. Install the steering stem assembly in the frame, holding it in place so that the balls cannot fall out. Fit the top bearing race and bearing cover. Install the bearing adjuster nut. Tighten the nut until all the play is taken out of the steering stem, but insure that the stem can turn freely.

4. The remainder of the procedure is the reverse of disassembly. Tighten the upper triple clamp fitting bolt to 26–29 ft lbs., and the steering stem pinch bolt to 10–16 ft lbs.

5. If the handlebars have been removed, tighten the clamp bolts evenly to yield a gap on both sides of the clamps. Tighten the clamp bolts to 10–16 ft lbs.

REAR SHOCKS

1. The rear shock absorbers are sealed units. No service is possible. If the shocks leak oil, have a bent damper rod, damaged damper case, or other damage, they should be replaced.

Shock absorbers should be replaced in sets to ensure equal damping characteristics.

2. Shocks can be removed by removing the upper and lower mounts. To remove the spring, set the load adjuster on the softest setting, compress the spring, and remove the spring retainers.

3. With the spring removed, check the damping characteristics of the unit. The damper rod should be able to be pushed into the damper body with considerably less effort than it takes to pull it out. If little or no resistance is felt when pulling a damper rod out, the shock should be replaced. Shocks should have equal damping characteristics.

4. Tighten the mounting bolts to 16–25 ft lbs when installing the shock absorbers.

SWING ARM

Inspection

1. Remove the mufflers.

2. Remove the rear wheel, shock absorbers, and chain guard.

3. Measure the distance between the top and bottom shock absorber mounts on both sides. The two measurements must be identical, or the swing arm will have to be replaced.

4. Check that the rear wheel mounting plates are parallel.

5. Grasp the legs of the swing arm and attempt to move it from side to side. Any noticeable side-play (more than 1 mm/0.04 in.) will indicate that the swing arm bushings need replacement.

The swing arm is most likely to be damaged if the machine is operated for any length of time with a broken or otherwise defective shock absorber.

Removal and Installation

1. Proceed as above. Then remove the swing arm pivot bolt nut and tap out the pivot with a long drift.

2. Remove the swing arm by pulling it straight back. Note the locations of any spacers or shims which may come off. They must be installed in their original locations.

3. The swing arm should be inspected for cracks or fractures, especially around the welds.

4. Remove the bushings, tapping them out with a hammer and punch. Once the bushings are removed, they should be replaced.

5. Lubricate new bushings with a good chassis grease. Press the bushings into the swing arm.

6. Clean out the pivot bolt and ensure that all grease passages are clear. Install the swing arm on the machine. Grease and install the pivot bolt. After tightening the swing arm pivot bolt nut, move the swing arm up and down to ensure that movement is smooth and effortless.

7. Pivot bolt torque is 36–58 ft lbs.

SERIAL NUMBER LOCATION

In order to prevent possible confusion when ordering parts, always refer to the engine and frame serial numbers.

The frame number is stamped on the right side of the steering head lug; the engine number is stamped on the crankcase behind the right cylinder.

MAINTENANCE

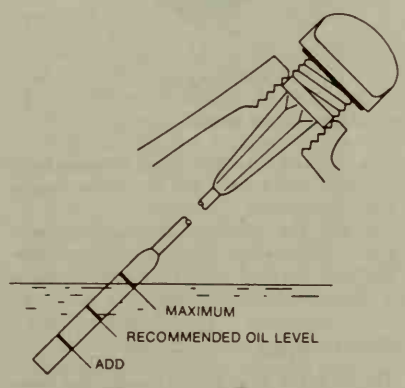
NOTE: *Common maintenance procedures are explained in detail in the "General Information" section.*

LUBRICATION

Motor Oil

When the average air temperature is above 5°C (41°F), use Yamalube® 4-stroke oil, or SAE 20W-40, service rating, "SE" or "SF."

When the air temperature is consistently below 15°C (59°F), use SAE 10W-30, service rating "SE" or "SF." All manufacturers recommend a certain grade and viscosity of motor oil for their engines, and this recommendation should be adhered to in order to ensure long engine life.



Checking Oil Level

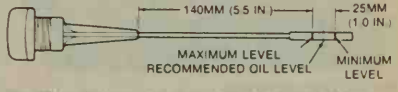
XS650H

1. A sight glass is provided on the right side of the crankcase which provides an immediate check on oil level.
2. The motorcycle should be parked on the centerstand on a level surface to insure an accurate reading.
3. Maintain the oil level between the marks inscribed on the crankcase. The engine should be run for a few minutes before checking.
4. If the level is low, add enough oil of the recommended grade to bring the level up to the upper mark. Do not overfill.

OTHER MODELS

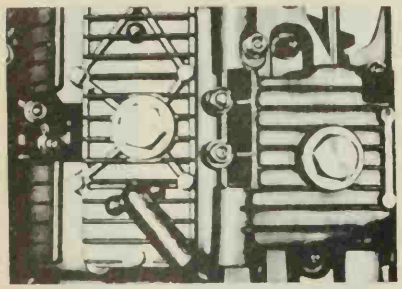
1. A dipstick is provided to check the oil level.
2. The motorcycle should be parked on level ground and put on the centerstand.

Dipstick marks



3. Unscrew and remove the dipstick and wipe it off. Reinsert the dipstick, allowing it to rest on the threads of the hole. Oil level should be between the maximum and minimum marks on the stick. If the oil level is too low, add enough oil to bring the level up to between the marks. Do not overfill the crankcase.

Note that the oil capacity for the 650 motor has been revised for 1974 and later models. 1975 650s after Engine No. 103747 have a modified dipstick to accommodate this change. Recommended oil level is midway between the max and min marks.



TX650A or early XS650B models which blow oil mist from the breather pipes should use the new lower level. Refer to the illustration of the modified dipstick.

Changing Oil

1. The recommended oil change interval is 2,000 miles or three months, whichever comes first.

Modified dipstick for 1975 and later models

Crankcase drain plugs (remove both when changing the oil)

2. Oil should be changed when the engine is warm. This ensures more complete draining, and makes it more likely that the oil will carry off any particular matter with it.

3. Place a suitably-sized container (at least 3 qt. capacity) beneath the crankcase drain plug. Remove both of the drain plugs and allow the oil to drain for several minutes.

4. Clean the drain plugs thoroughly, removing any metal particles or foreign matter. Check the condition of the drain plug gaskets. Replace the gaskets if damaged. Install the drain plugs and tighten them securely. Proper torque is 25–30 ft lbs.

5. If the oil filter is to be serviced and/or the filter screen cleaned, refer to the procedures outlined below. Note that the quantity of oil to be added to the crankcase will depend on whether or not the filter is being serviced.

6. Refer to the "Maintenance Data" chart at the end of this section for the proper quantity of oil. Add the oil to the crankcase, start the engine and allow it to idle for about one minute. Stop the engine and let it sit for a minute. Then check the oil level with the dipstick (see above for procedures if necessary) or at the level glass.

Top up the crankcase, if necessary, so that the oil level is between the two lines on the dipstick or at the level sight glass.

Oil Filter

The crankcase cover oil filter should be cleaned every 4,000 miles or every other oil change.

1. Drain the crankcase oil as outlined in Steps 1–4, above.

2. Remove the allen bolts which secure the oil filter cover plate to the right side crankcase cover and remove the cover plate.

3. Separate the sealing O-ring from the cover plate and inspect it for damage. Replace it if necessary, as a good seal is essential.

Oil filter retaining bolt

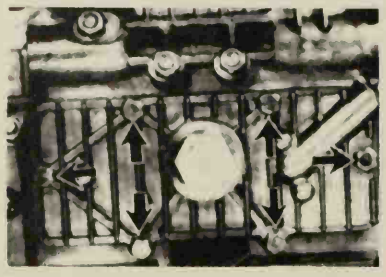
4. Remove the oil filter retaining bolt and pull out the filter.

5. Clean the filter in a clean, safe solvent and dry it with compressed air. Check for damage or for any particulate matter lodged in the outer mesh.

6. Clean out the filter cavity in the crankcase cover.

7. Reinstall the filter, securing bolt, and the cover plate and O-ring.

CAUTION: *Do not overtighten the filter securing bolt, as this could cause the filter to collapse.*

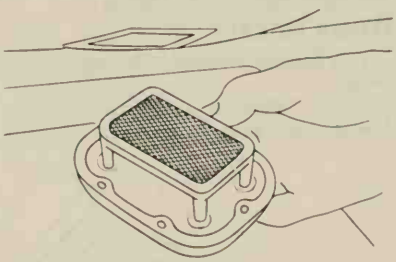


8. Tighten the cover plate allen bolts evenly. After refilling the crankcase with the proper grade and quantity of oil, start the engine and check for leaks.

Filter Screen

The oil filter screen is fitted to the bottom of the crankcase. The filter screen should be removed and cleaned every 4,000 miles or at every other oil change. A new cover plate gasket should be used.

1. Drain the crankcase oil as outlined in Steps 1–4 under "Changing Oil," above.



2. Remove the six filter screen cover plate bolts from the bottom of the crankcase. Remove the cover plate, gasket, and filter screen.

Filter screen cover plate bolts

3. Clean the filter screen of any foreign matter with a safe solvent. Blow it dry with compressed air.

4. When reinstalling the filter screen and cover plate, the use of a new cover plate gasket is recommended.

Removing the filter screen

5. Tighten the cover plate securing bolts gradually and evenly and in a cross pattern until all are tight.

6. Fill the crankcase with the correct grade and quantity of oil as given in the charts at the end of this section. Start the engine and check for leaks.

Front Forks

The oil in the forks should be changed every 4,000 miles, or more frequently if the machine is operated under extremely dusty conditions.

1. Yamaha fork oil, SAE 10W-30 motor oil (service-rated "SE" or "SF"), or any other high-quality special motorcycle fork oil can be used.

1. Yamaha fork oil, SAE 10W-30 motor oil (service-rated "SE"), or any other high quality special motorcycle fork oil can be used.

Oil viscosity can be varied if slightly stiffer or less stiff fork action is desired. While special types of oil designed specifically for motorcycle forks can be used, care must be taken to flush the forks thoroughly when changing types or brands of fork fluid, since some may be incompatible with others.

2. Refer to the "Maintenance Data" chart at the end of this section for fork capacity. This will vary according to model year.

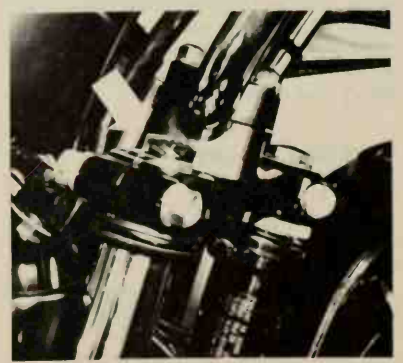
3. Support the front wheel off the ground by placing a jack or the like beneath the engine.

CAUTION: *Be sure that the motorcycle is properly supported.*

4. Remove the rubber caps fitted to the tops of each fork leg, if applicable. Unscrew and remove each of the fork filler caps.

5. Remove the fork springs on later-type internal spring forks.

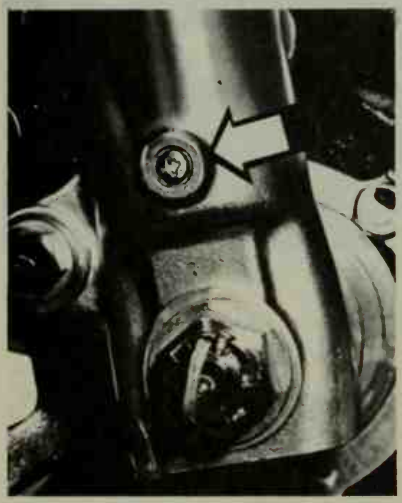
6. Place a suitable container beneath one of the fork sliders and remove the drain screw. After most of the oil has drained off, pump the slider up and down a few times to remove all of the oil in it. Check the condition of the drain screw gasket and replace it with a new one if necessary. Refit the drain screw and tighten it securely.



7. Repeat the procedure with the remaining fork leg.

8. Examine the drained oil. If it contains water or is exceptionally dirty, it may be that the fork dust covers or gaitors are damaged and allowing foreign matter to get past. This will also damage the fork seals quickly. Check that the dust covers are properly secured, or replace them if they are cracked, ripped, or otherwise damaged.

9. Add the proper grade and quantity of oil to each of the fork legs.



10. Check the condition of the fork filler cap O-rings and replace them if they are cracked or ripped. Refit the springs on internal fork spring forks and install the filler caps. Tighten the filler caps securely.

11. After several miles of operation, check the area around the fork slider seals for leaks or seepage. Even a minimal amount of seepage will require replacement of the seals. A

Front fork filler cap

coating of grime building up in this area over a period of time is also indicative of ineffective seals.

Front fork oil drain plug

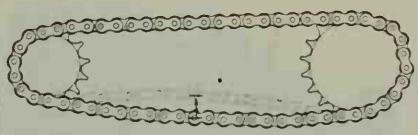
Chassis Lubrication

1. The swing arm pivot is fitted with one or two grease nipples which should be lubricated with a good grade of chassis grease every 2,000 miles. Apply grease until it shows at both ends of the swing arm pivot. Wipe off the excess.

Swing arm pivot grease fitting

2. Wheel and steering head bearings are lubricated with bearing grease, the service interval being 8,000 miles. Be sure to obtain a good quality bearing grease. The older types are often not suitable for use.

SERVICE CHECKS AND ADJUSTMENTS

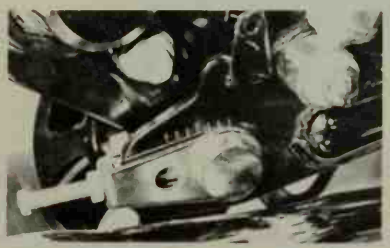


Drive Chain

1. The chain should have about 10–20 mm (0.4–0.8 in.) of total up-and-down free-play measured in the middle of the lower chain run.

2. Before checking or adjusting the chain slack, the following conditions should be met:

a. The motorcycle should be placed on both wheels with a rider sitting with his weight on the seat.



b. The transmission should be placed in neutral;

Drive chain slack is measured in the middle of the lower chain run

c. The chain should be clean and well-lubricated;

d. The chain should have been checked for any tight spots by slowly rotating the wheel and checking for variances in the chain tension at different points. If a tight spot exists, the chain tension should be adjusted to the prescribed free-play at the tight spot. Note, however, that such a condition is indicative of a worn chain and probably worn sprockets, which should be replaced as soon as possible.

Chain adjusting bolt and swing arm alignment marks

3. Remove the axle nut cotter pin and loosen the axle nut several turns. Loosen the locknut on each chain adjuster bolt.

4. Turn each of the adjuster bolts in or out by equal amounts until the chain tension is approximately correct.

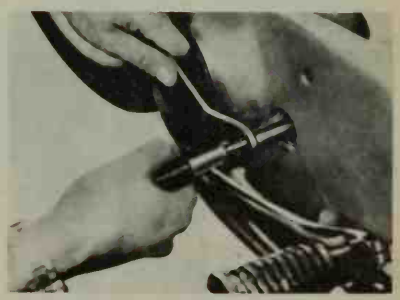
5. Check wheel alignment by means of the aligning marks inscribed on both sides of the swing arm. Be sure that both adjusters are lined up with the same mark on each side. If not, turn one of the adjuster bolts in or out so that alignment is achieved.

6. Tighten the axle nut and adjuster bolt nuts and check the chain tension. The chain tension should also be checked with the weight of a rider sitting on the motorcycle when it is off the center stand, the chain should still have at least ½ in. of free-play. Correct if necessary. After adjustment is correct, torque the axle nut to 87–130 ft lbs.

Fit a new cotter pin.

Clutch

1. Cable adjustment must always be maintained at the proper specification. If the cable has insufficient free-play, the clutch will slip and rapidly burn out. If it has too much play, the clutch will not completely disengage, resulting in hard shifting and creeping at stops.



2. Use the cable adjuster at the handlebar to maintain the correct amount of cable slack. The clutch hand lever should be able to be moved 2–3 mm (0.08–0.12 in.) measured between the lever and the lever holder before the clutch begins to disengage.

If clutch operation is not satisfactory after making this adjustment, proceed as follows:

3. Screw the cable adjuster at the lever in all the way thus increasing cable free-play.

Clutch cable free-play (arrow) should be 2–3 mm (0.08–0.12 in.)

Adjusting the clutch

4. Remove the clutch adjuster cover plug on the left crankcase cover. Loosen the clutch adjusting screw locknut.

5. Turn the adjusting screw clockwise until a slight resistance is felt, then turn it counterclockwise ¼ turn. Holding the screw in this position, tighten the locknut.

6. Turn the cable adjuster out until there is about 2–3 mm (0.08–0.12 in.) of free-play in the hand lever. Tighten the locknut on the cable adjuster.

Throttle Cables

1. The throttle cable is fitted with an adjuster at the twist-grip. The twist-grip should be able to be rotated approximately 10–15° before the butterflies begin to open.

2. Use the cable adjusters at the handlebar to make and maintain this adjustment. To check that the cable has sufficient slack, start the engine and turn the forks slowly from lock-to-lock. Idle speed must not increase. If it does, it indicates that the cable has insufficient free-play, is incorrectly routed, or is binding at some point.

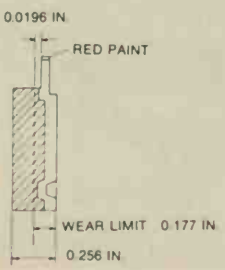
Throttle cable adjusters

Brakes

FRONT DISC

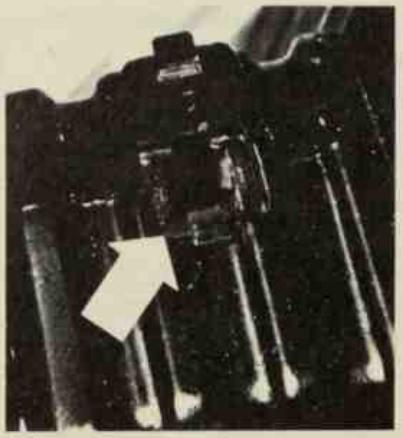
Disc brakes need little attention other than a periodic check of the fluid level and of pad wear.

1. Check the brake fluid level in the master cylinder reservoir. On older models, the master cylinder cap and diaphragm must be removed. The fluid level line is inscribed on the inside of the reservoir. Later models



Front master cylinder brake fluid level line

have a see-through plastic reservoir which can be checked at a glance. If the fluid level is below the inscribed level mark, add enough DOT 3 type hydraulic disc brake fluid to bring the level up to the mark. Reinstall the diaphragm and cap and tighten it securely.



NOTE: *To keep the brake fluid clean, wipe any dirt or foreign matter off of the reservoir before removing the cap. Do not leave the cap off for extended periods of time. Do not allow water to get into the reservoir. Do not apply the brake while the cap is removed. Do not overfill the reservoir. Fluid level will drop slightly as the pads wear. Fitting new pads will usually restore the fluid level to its original line. .*

2. Brake pads should be replaced, as a set, if either or both are worn. Late models have a red wear indicator line inscribed on the pads. Replace them when they are worn to the red line. On earlier models the pads should be replaced when they are worn to a thickness of 0.18 in. or less.

3. If the brake lever feels spongy, or if brake effectiveness has been reduced, a possible cause is air bubbles in the lines. To remedy this, bleed the system. This procedure can also be found in chapter 8, "Chassis."

Old style brake pad wear limit

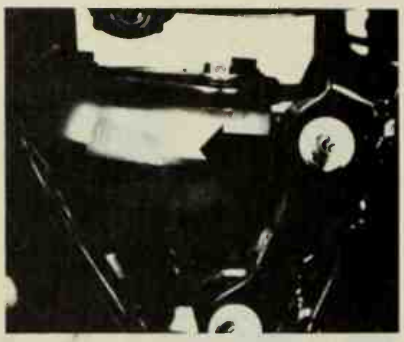
Check brake pad wear here

4. The brake lever should have about 13–25 mm (0.5–1.0 in.) of movement which is measured at the tip of the lever.

Lever movement is adjustable by means of an adjusting screw near the lever holder. Once set properly, the lever travel will not ordinarily need readjustment. If lever travel becomes excessive, it is more probable that the system needs to be bled or has some other fault. Adjusting the brake lever travel will not remedy any brake system faults.

REAR DISC

Refer to the "Front Disc" section preceeding for general information. On late models, front and rear brake calipers are identical units.



1. The transparent master cylinder reservoir allows inspection of the fluid level without removing the master cylinder cap. If the fluid level is below the level mark, remove the cap and diaphragm and add enough DOT 3 brake fluid to bring the level up to the mark. Reinstall the diaphragm and cap and tighten it securely.

2. Pad wear can easily be checked by visual inspection. Replace the pads, as a set, if either of them is worn to the red limit line.

3. To adjust brake pedal height and free-play, loosen the height adjuster bolt locknut. Turn the adjuster bolt in or out so that the top of the pedal is about 12–18 mm (0.5–0.7 in.) below the top surface of the footpeg rubber. Tighten the adjuster bolt locknut.

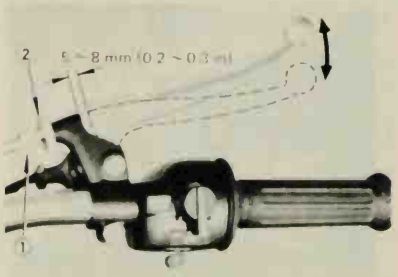
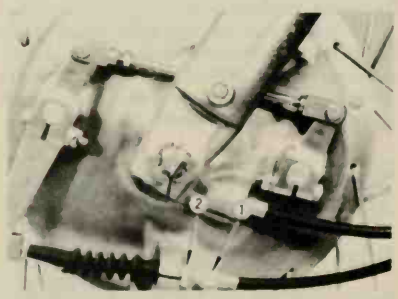
Rear master cylinder brake fluid level line



Loosen the brake rod adjuster locknut and turn the brake rod until there is noticeable free-play between the rod and the master cylinder. Turn the brake rod in until it just touches the master cylnder, than back it out about 1½ turns. Tighten the locknut.

CAUTION: *The pin hole mark on the brake rod must not show above the locknut.*

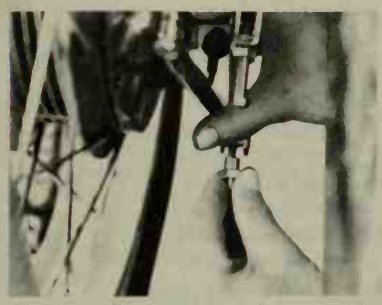


The adjustment should yield brake pedal free-play of 13–15 mm (0.5–0.6 in.).

FRONT DRUM

1. The brake should be adjusted so that the lever has 5–8 mm (0.2–0.3 in.) of free movement measured between the lever and the lever holder before the linings contact the drum.

Brake lever free-play showing cable adjuster and locknut (1 and 2)



Brake plate adjuster and locknut (1 and 2)

2. The brake can be adjusted with either the cable adjustor at the brake plate or the adjustor on the handlebar. Loosen the locknut and turn the adjustor out to decrease brake lever movement. It is recommended that major adjustments be made with the adjuster at the brake plate and finer adjustments with the handlebar adjustor.

REAR DRUM (EARLY)

1. Rod-operated rear brakes should be adjusted with a rider on the machine and the machine off the center stand. In this position,

Adjusting the rear brake

the brake should be adjusted by means of the adjuster nut on the brake rod to yield ½–1 in. of brake pedal travel before the brake linings fully contact the drum.

2. On drum brakes, the angle formed by the brake rod of brake cable and the actuating lever on the brake drum should not exceed 90° when te brake is fully applied. If it does, it is time to replace the linings. Late models are fitted with wear indicators.

3. After adjusting the brakes, be sure to check operation of the brake light.

REAR DRUM (LATE)

1. Brake lining wear can be determined by means of the wear indicator pointer fitted to the brake lever on the hub. If the pointer lines up with the red slash mark when the brake pedal is fully applied, the linings are worn as far as possible for effective braking and should now be replaced.

2. Observe the angle formed by the brake lever on the hub and the brake rod when the brake is fully applied. When the lever and rod form an angle greater than 90°, the shoes should be checked for wear as they probably are worn to the point of needing replacement.

3. The rear brake should be adjusted so that there is approximately 25 mm (1.0 in.) free-play at the pedal before the linings contact the drum. Adjust by turning the nut on the brake rod. When adjustment has been made, be sure that the nut is seated properly on the brake lever pin. Also, check the operation of the brake light switch.

Brake Light Switches

The switches should be checked for operation after the brakes are adjusted. The rear brake light switch and adjuster nut are mounted on a slotted bracket. The rear switch is adjusted by holding the switch and turning the adjuster nut to effect adjustment. Moving the switch up on the bracket allows the brake light to turn on sooner. Moving it down allows the light to turn on later. Do not turn the switch to effect adjustment as the wires will become twisted and may break.

The front disc brake switch is activated by the pressure of the brake fluid in the brake line. This switch is not adjustable; if defective, it must be replaced.

Headlight Adjustment

1. Set the machine about 25 feet away from a wall, preferably of a color which reflects light well.

The machine should be off the stand, and

Headlight lateral adjustment screw

with a rider putting his weight on the machine as in operation.

2. Switch on the high beam. The headlight high beam should be parallel to the ground and should hit the wall directly in front of the machine.

3. Vertical adjustment is made by first removing the headlight rim anchor screw and removing the headlight by prying at the point provided at the bottom. Slightly loosen the two headlight shell mounting nuts and install the headlight. Adjust the headlight by pivoting the shell up or down as needed. Remove the headlight and tighten the two mounting bolts. Install the headlight and tighten the anchor screw.

4. Lateral adjustment is accomplished by turning the adjusting screw on the side of the headlight. Tighten the screw to move the beam to the right; loosen it to move the beam towards the left.

FUEL SYSTEM

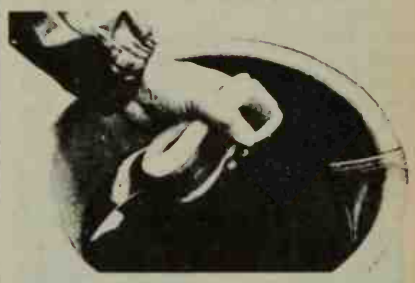
The fuel system consists of the carburetors, petcock(s), and air cleaner(s).

These items should be serviced every 2,000 miles when the machine is used under normal conditions.

Air Cleaner

1. The air filter may be either a pleated paper element or a foam-type cleaner depending on model and year.

2. While the normal maintenance interval for air filters is 2,000 miles, cleaning or replacement may be necessary more frequently if the machine is used in a dusty environment.



3. Paper elements can only be cleaned by brushing any deposits of dirt from the outside of the filter elements with a stiff, non-metallic brush. If compressed air is available, blow through the inside of the filter to remove any dirt from the paper pores.

This procedure is only marginally effective. After 3 or 4 such cleanings, the filter should be replaced with a new one.

Paper filters must be kept dry. Do not attemp to clean them in solvents or any other liquid.

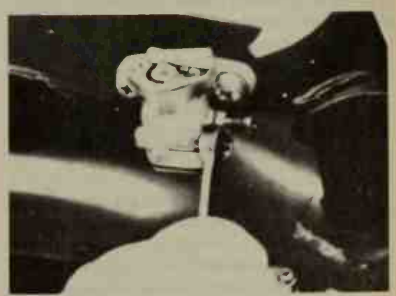
Blowing dirt out of a paper element filter with compressed air

Squeeze, do not wring, foam-type filter elements

4. Foam-type air filters depend upon oil-coated pores to catch dirt particles. These filters are semi-permanent, and may be cleaned by immersing them in a solvent such as kerosene and then squeezing them dry.

Do not wring the filter as the fabric may be damaged.

Soak the element in clean SAE 10W-30 motor oil and squeeze out the excess. Then refit the filter to the motorcycle.



5. XS650C and later models use a dry-foam element which is serviced in the same manner as the paper-type filters.

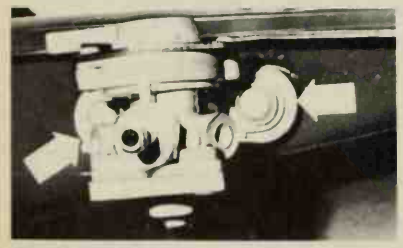
Petcock

1. One or two petcocks are used, depending on model year. The petcock contains the fuel filter screen(s) which should be cleaned every 2,000 miles.

2. Several different types of petcock have been fitted over the years. The most common type has a sediment trap incorporated into it as well as a fuel filter screen on the outlet pipe.

3. After ensuring that the petcock lever is in the "off" position, place a small container beneath the petcock and remove the sediment trap drain bolt. After the trap has drained, inspect the bolt gasket, replace it if

Removing the petcock sediment trap drain bolt



Removing the outlet pipe and filter

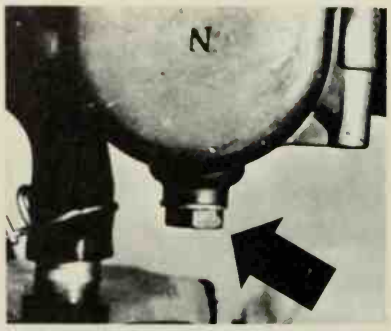
necessary, and refit the bolt, securing it tightly.

4. Check that the outlet pipe is the removable type by noting the presence of a hex fitting on the pipe. Disconnect the fuel line from the outlet pipe, after first ensuring that the petcock lever is in the "off" position. Unscrew and remove the outlet pipe. Clean the filter screen in gasoline and blow dry. Remove any foreign matter trapped in the screen. Check the screen for holes or other damage. If the screen is punctured, or if it cannot be properly cleaned, replace it with a new one.

After reassembly, turn on the fuel and check for leaks before operating the motorcycle. Be sure that the fuel line is tightly secured to the outlet pipe with its spring clip or with safety wire.

5. The petcock is usually secured to the gas tank by two screws. Sealing is accomplished by means of a rubber O-ring. The petcock can be removed from the tank when it is empty by removing the two securing screws. Disassemble the petcock by removing the outlet pipe, the sediment trap

Petcock securing screws



bolt, and the two screws which secure the plate to the petcock body. Clean all metal components thoroughly in gasoline. Before installation, check the condition of the rubber O-ring and replace it if it is chipped or cracked, or if it fails to form an effective seal.

Carburetors

Thorough cleaning of the carburetors, which should be carried out every 2,000 miles under normal conditions, requires removal of the units from the machine.

On some models, the carburetor float bowls are fitted with drain plugs which can be removed periodically to flush out any water or other foreign matter which may have passed through the system.

Before removing carburetor float bowl drain plugs, be sure that the fuel petcock(s) are in the "off" position. This operation should also be avoided when the engine is hot due to the danger of fire from gasoline spilling on the hot engine.

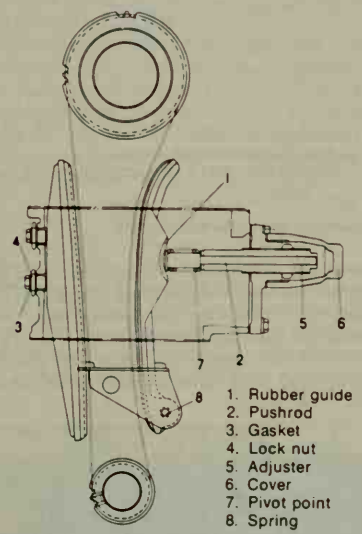
TUNE-UP

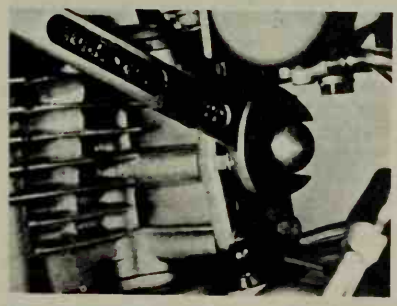
NOTE: *Common tune-up procedures are explained in detail in the "General Information" section.*



COMPRESSION TEST

1. A compression check should be made before each tune-up since this will provide a general idea of engine condition.
2. It is necessary to have a gauge with the proper adapter (plug holes are 14 mm) if a screw-in type gauge is used. The less expensive "hold in" type gauges can also be used. Use some oil on the rubber tip to ensure a good seal.
3. The engine should be at operating temperature when checking compression.
4. Remove both of the spark plugs and fit the gauge to one of the plug holes.
5. Close the choke and hold the throttle wide open while spinning the engine with the starter motor or the kickstarter. Note the higest compression reading and repeat the test with the remaining cylinder.
6. Compression may vary according to gauge tolerance and several other factors. However, it should normally be between 130 and 145 psi. Both cylinders must be within 15 psi of this range and of each other.

CAM CHAIN ADJUSTMENT

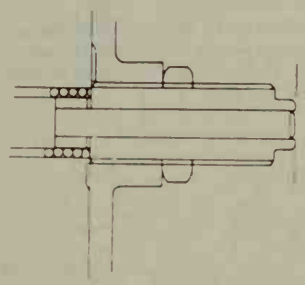


1970–75 Models

1. The cam chain tensioner is located at the rear of the cylinders, between and below the intake ports.
2. The cam chain tension should be checked every 2,000 miles.

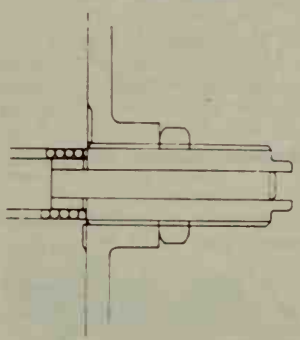
Cam chain tensioner assembly

3. Slowly rotate the engine in the normal direction of rotation (counterclockwise when viewed from the engine's left side). One rotation should be sufficient to place all of the cam chain slack on the tensioner side.
4. Remove the tensioner cover. Loosen the tensioner locknut, then turn the adjuster



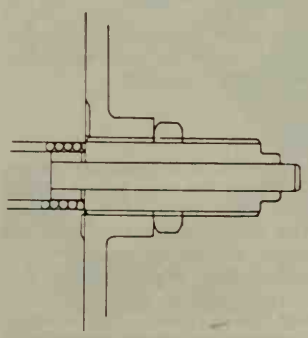
Removing the tensioner cover

in until the end of the tensioner pushrod is flush with the end of the adjuster.



5. Tighten the locknut. Install the tensioner cover.

1976–81 Models



1. The cam chain adjuster is located between and at the rear of the cylinders.
2. Remove the adjuster cap nut.

3. The end of the pushrod should be flush with the end of the adjuster bolt.
4. If it is not, turn the adjuster bolt until it is flush with the end of the pushrod.
5. Install the cap nut.

VALVE ADJUSTMENT

NOTE: *Valves must be adjusted when the engine is cold.*

1. Remove the intake and exhaust valve covers, and the alternator cover. Remove the spark plugs.
2. Place a thumb over each spark plug hole, and kick the engine over slowly until compression is felt in one of the cylinders.
3. Continue turning the engine over (in the normal direction of rotation) using a

Rotor "T" mark aligned with stator mark

Adjusting the valve clearance

wrench on the alternator rotor nut until the reference mark on the rotor lines up with the "T" mark on the stator. The pistons are now at top dead center, and the cylinder in which you felt compression should be at the top of its compression stroke. Both valves for this cylinder will be closed, and these are to be adjusted first. Verify that this cylinder is at TDC on the compression stroke by checking for slack at its intake and exhaust valve adjusters.

4. Insert the proper size feeler gauge between valve stem and tappet. There should be a light drag when pulling out the feeler gauge blade, if the valve is correctly adjusted.

Proper valve clearances are as follows:

Model	Intake (in./mm)	Exhaust (in./mm)
XS1/1B/2, TX650	0.003/0.08	0.006/0.15
TX650A, XS650B	0.002/0.05	0.004/0.10
XS650C/D	0.002/0.05	0.006/0.15
XS650E/F/G/H	0.004/0.10	0.006/0.15

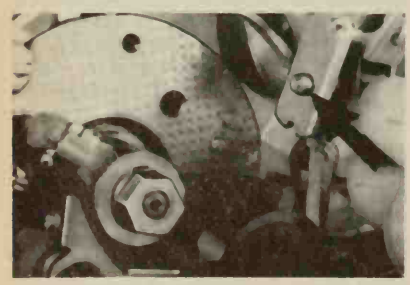
5. If adjustment is necessary, loosen the adjuster locknut, and turn the adjuster in or out until the proper clearance is obtained. Hold the adjuster securely and tighten the locknut.

6. Rotate the crankshaft 360° and repeat the procedure with the other cylinder.

NOTE: *An alternative method is to adjust each valve when it is closed without regard to piston position. To do this, remove the valve covers and spark plugs, and turn the engine over slowly with the kick-starter while watching the valve action. When the left intake valve is open (the rocker arm will be depressed), the* RIGHT *intake valve will be closed, and can be adjusted for the proper clearance. When the left exhaust valve is opened, the* RIGHT *exhaust valve can be adjusted, etc.*

CONTACT BREAKER POINTS

Location



The contact breaker points are opened and closed by a cam on the end of the camshaft and are located beneath a cover on the left side of the cylinder head.

The timing advance mechanism is located on the opposite side of the cylinder head beneath its own cover.

Replacement

1. Points sets are available already mounted on the breaker plate, or may be purchased separately.

2. If the points are purchased separately, disconnect the primary wire at each point set, remove the securing screw, and remove the old points. When installing new points, note that the proper installation of the insulating washers at the primary terminal is critical. If improperly installed, no spark will occur. There is a small insulating washer which fits around the terminal bolt and two insulating washers, one immediately on either side of the terminal bracket. All connectors (condenser, primary wire, points spring) are made on the outer sides of these washers (i.e., no connector must touch the bracket, which is a ground).

Be sure that the locating pin is seated in its hole

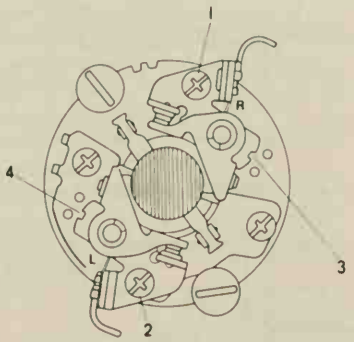
3. New points may have a protective coating on the contact surfaces to prevent oxidation. Clean off these surfaces with a non-oily solvent before attempting to start the machine.

4. If the motorcycle will not start immediately after installation of new points, check that the primary wire connections are tight, that the insulating washers at the primary terminal are properly installed, and that the contact surfaces are thoroughly cleaned.

5. The condensers are mounted on the left side of the top engine mounting bracket. They must be replaced as a set.

Gapping

Points should be filed (if necessary) and cleaned before gapping.



1. Remove the points cover.

2. Turn the engine over until one of the two sets of points is fully open.

3. With the proper feeler gauge blade, check the gap. The proper specification is 0.3–0.4 mm (0.012–0.016 in.), and the blade should be a slip fit between the points if the gap is correct.

4. If adjustment is necessary, loosen the screw which secures the point set to its plate, and use a small screwdriver at the pry point provided to adjust the gap.

CAUTION: *Loosen the screw just enough to allow the points to be moved. If loosened too much, the points will snap shut instead of holding the gap.*

Point gap adjustment screws (1,2) and pry points (3,4)

5. Tighten the screw and recheck the gap. It may change slightly when the screw is tightened.

6. Repeat the procedure with the remaining points set. Try to adjust both sets so that the feeler gauge blade has the same "feel" in both sets. This will help to ensure accurate timing.

7. If it is not possible to gap the points correctly, the fiber heel is evidently worn; the points should then be replaced.

Lubrication

1. On all models it is necessary to occasionally lubricate the cam follower fiber heel and the pivot point of the contact breaker. This minimizes wear and ensures that the timing will remain accurate for a longer period. A worn heel will retard the timing.

2. A small dab of grease (high melting point, if possible) should be applied to the lubricator wick so that the lubricator can distribute it onto the breaker cam. A drop of engine oil should be applied to the pivot point.

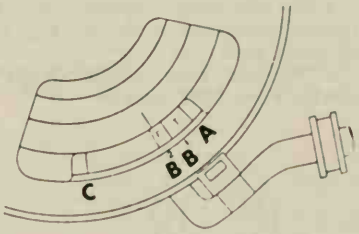
3. In both cases it is imperative that care be taken to keep the lubricant away from the points contact surface.

4. The lubricating wick should be adjusted so that it just contacts the breaker cam.

IGNITION TIMING

Breaker-Point Models

NOTE: *Points must be cleaned and gapped before checking timing. Dirty points will cause inaccurate readings.*



Remove the points cover and observe the breaker plate. Note that the points for the right cylinder (grey lead) are mounted directly to the large breaker plate, while the points for the left cylinder (orange lead) are mounted on a small moveable plate. Therefore, the right cylinder timing must be set *first*, since adjustment involves turning the entire breaker plate, which will alter the timing of the left cylinder as well. The points for the left cylinder are adjusted by moving only the points themselves.

NOTE: *Be sure the cam chain is properly adjusted.*

1. Remove the alternator inspection plate, ignition points cover, and centrifugal advance unit cover.

2. Inspect, clean and gap the points.

3. Ignition timing is set by matching the marks on the alternator stator and rotor. The

A-TOP DEAD CENTER

C-MARK FOR "FULLY ADVANCED" IGNITION TIMING

Alternator rotor reference marks

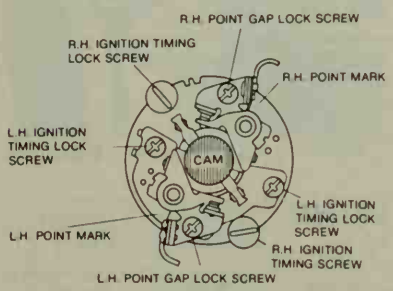
rotor has one reference timing mark and the stator has four: the first mark (to right of the letter "T") identifies Top Dead Center, the next two marks (either side of the letter "F") identify idle timing (fully retarded) and the remaining mark identifies high speed timing (fully advanced).

4. Secure the centrifugal advance coun-

Timing advance mechanism weights held in the retarded position

terweights in the fully retarded idle position (held inward).

5. Connect an ignition timing light or point checker as follows:



(+) RED lead—to grey point wire connector

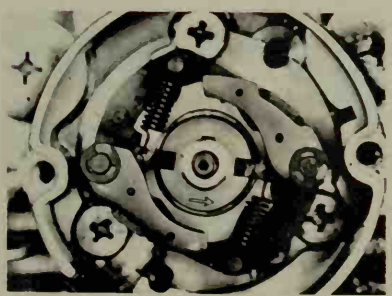
(−) BLACK lead—to ground (frame or engine case)

Right and left cylinder point sets are marked "R" (grey wire) and "L" (orange wire), respectively.

NOTE: *The right cylinder timing MUST be set first. The right cylinder points are mounted directly to the base plate, the left cylinder points are mounted on a separate plate; therefore, setting the left side first would cause a position shift when timing the right.*

6. Turn the crankshaft in the direction of normal rotation until the right cylinder

Breaker point ignition timing screws



points begin to open (as indicated by the timing light or point checker).

7. Loosen the base plate screws and turn the plate in either direction so that the points begin to open when the rotor mark is aligned with the letter "F."

NOTE: *On engines with serial numbers below 11764, align the rotor with the mark to the left of the letter F.*

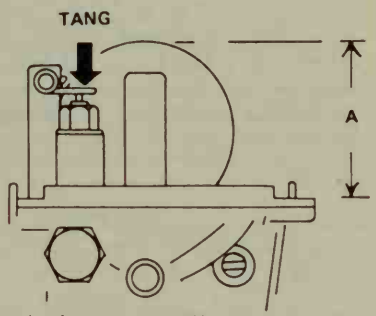
8. Rotate the engine 360°. Switch the (+) RED lead to the orange point wire connector and check the timing as before. The points should just begin to open when the "F" mark is aligned with the rotor mark. If adjustment is necessary, loosen the screws which secure the left cylinder's points to the base plate, and turn the points as needed to adjust the timing.

9. After idle timing has been set on both cylinders, secure the centrifugal advance counterweights in the fully advanced (held outward) position: the points should open at the full advance stator mark or within 3 mm of the mark. Make any necessary adjustments and recheck the idle timing.

Timing advance mechanism

NOTE: *If the correct marks align at the idle timing position, but full advance timing is not correct, the ignition advance weight stoppers can be bent slightly to increase or decrease the amount of full advance. Bend them out to increase the amount of full advance, in to decrease it.*

TCI Models



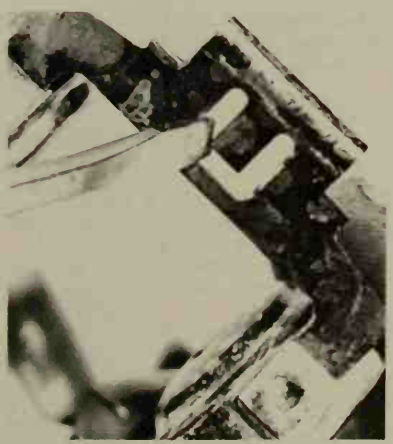
Transistorized ignition models do not require periodic ignition adjustments or maintenance.

CARBURETORS

Carburetor adjustments to be made during a tune-up include setting float level, synchronization, and idle speed and mixture.

Adjusting Float Level

1. Float level is a measure of the amount of gasoline which will be in the float bowls during operation. While it is a critical specification, it will not normally need readjustment once properly set. Float level, therefore, need not be checked at every tune-up, but should be attended to from time to time.



Float level measurement (A)

2. Remove the carburetors from the motorcycle.

3. Remove the float bowls. Remove the gasket. With the carburetor(s) positioned vertically, lower the float until the float arm just touches but does not depress the tip of the float needle. Float level is the measured distance from the bottom of the float to the float bowl mating surface.

4. Float levels are as follows: XS650C-H: 25.0 mm/0.98 in.

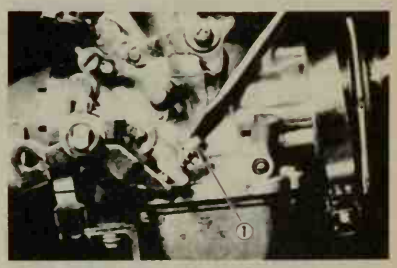
Adjusting the float tang

All other models: 24.0 mm/0.94 in. Adjust, if necessary, by pushing out the float pivot pin, removing the floats, and bending the float arm tang. Bending the tang towards the carburetor body will increase the float level measurement and vice-versa.

5. Both carburetors must have the same float level. Measure both before changing either. Note that the measured float level will be inaccurate if the float needle tip is worn or if there is foregn matter on the needle seat.

Idle Speed and Mixture

NOTE: *Idle speed and idle mixture adjustments must be made when the engine is at operating temperature.*



1. Except on XS650E-H models which have factory-installed idle mixture limiter caps on the screw heads, turn each pilot screw in until it bottoms lightly, then back each one out the proper number of turns:

Adjusting the pilot screw

XS1/1B: ½ turn
XS2, TX650/A, XS650B: ¾ turn
XS650C/D: 1½ turns

XS650E-H models are preset at 2¼ turns out and adjustment is not necessary unless the pilot screws have been removed for carburetor rebuilding.

Adjusting the throttle stop screw

2. Use the throttle stop screw on each carburetor so that the engine idles at 1,000–1,200 rpm and both cylinders run evenly.

3. To check that both cylinders run evenly, turn up each throttle stop screw so that the engine idles at about 1,500 rpm. Disconnect one spark plug lead. Back out the throttle stop screw of the running cylinder until the engine just dies. Connect the spark plug lead, restart the engine, and disconnect the plug lead of the cylinder which has just been adjusted. Back out the throttle stop screw of the running cylinder until the engine just dies. Restart the engine with both plugs connected, rev it a few times to clean off the plugs, and back out each throttle

stop screw in small, even increments until the desired idle speed is obtained.

Synchronization

The easiest method of synchronizing the carburetors is to operate the twist-grip slowly and observe the movement of the throttle arms on each carburetor.

The throttle arms should begin and end their movements at the same time. If they do not, adjust the throttle cable free-play so that synchronized movement is achieved.

NOTE: *The idle speed must be properly set before synchronization is attempted.*

After adjusting cable free-play, check that they are not too tightly adjusted by moving the forks slowly from lock-to-lock with the engine idling. Idle speed must not vary. If it does, this indicates that one or both of the throttle cables is too tightly adjusted. The twist-grip should have 10–15° of free rotation before the throttle arms begin to move.

NOTE: *If trouble is encountered during the idle speed or synchronization procedures, first check that the throttle cables have sufficient free-play. Make sure that the throttle stop screw for each carburetor is resting against its stop when the throttle is closed. If the trouble persists, check for air leaks at the manifolds. If this fails to reveal the problem, the fuel system may need an overhaul. Check for poor fuel flow, clogged filters, air leaks, and so on.*

14. Remove the horn and mounting bracket.
15. Remove the left case over.
16. Disconnect the master link and remove the final drive chain. "Endless" chains require a chain breaker for removal.
17. Remove the left footrest.
18. Remove both exhaust header pipes.
19. Remove the engine cylinder head mounting brackets.
20. Remove the brake pedal.
21. Remove the engine mounting bolts in the order shown in the illustration, then left the engine out the left-side of the frame.
22. Installation is the reverse of removal. Tighten the 10 mm mounting bolts to 26 ft lbs., and 8 mm mounting bolts to 15 ft lbs.

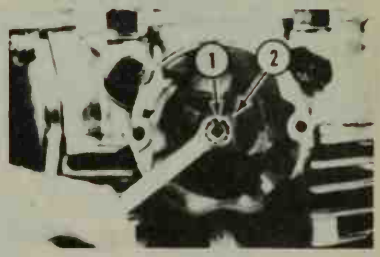
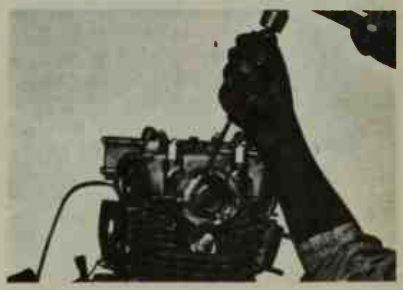
TOP END

To remove the cylinder head cover and/or cylinder head, it is necessary to remove the engine from the frame. Refer to the section above for the procedure.



Cylinder Head Cover

REMOVAL



1. Remove the oil delivery line at the front of the engine between the cylinders.
2. Remove the points and base plate by removing the two securing screws.
3. Remove the advance mechanism locknut and plate.
4. Pull the advance rod out the left (point) side.
5. Tap loose the advance mechanism ring nut, then slide out the unit. Also, remove the advance locating pin.
6. Remove the 3 attaching screws and the advance mechanism housing.

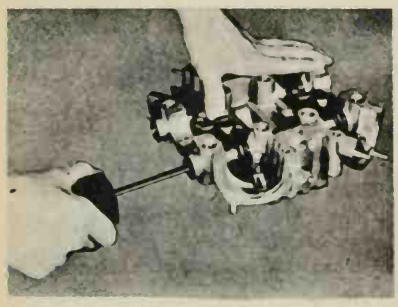
7. Remove the 4 tappet covers.
8. Remove the 8 retainer nuts, 4 retainer bolts, and the head cover. Make certain to remove the nuts and bolts in the sequence shown in the illustration.
9. Remove the rocker shaft covers, sleeves, and O-rings.
10. Remove the rocker arm shafts and arms using a 6 mm extracting screw.

INSPECTION



1. Check the rocker arm for excessive wear at the two points indicated in the illus-

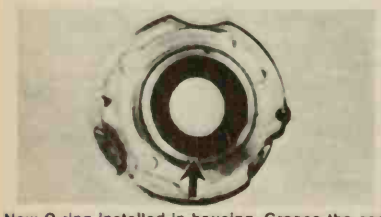
tration. Look for any grooves, scratches, discoloration, or flaking of the hardened surfaces.

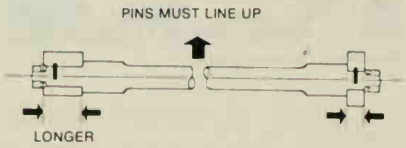


2. Measure the rocker shaft hole with an inside micrometer. Standard size is 15.03 mm. Also measure the rocker shaft diameter and check for step wear or discoloration. Standard diameter is 14.98 mm.

3. Normal shaft-to-rocker arm clearance is 0.05 mm. The maximum clearance is 0.10 mm.

INSTALLATION

Reverse the removal procedure and note the following:



1. Coat all parts with oil before assembling.

New O-ring installed in housing. Grease the seal lips before installation

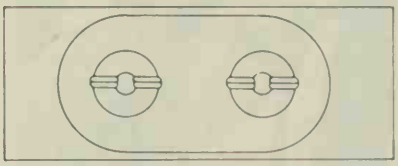
2. Make sure that the rocker arms are installed with the tapped end pointed outward.

3. Coat mating head and cover surfaces with Yamaha Bond #4.

4. Torque 10 mm nuts to 22–25 ft lbs, 10 mm stud bolts to 11–15 ft lbs, 8 mm bolts to 15–18 ft lbs and 6 mm bolts to 8–11 ft lbs in the order shown in the illustration.

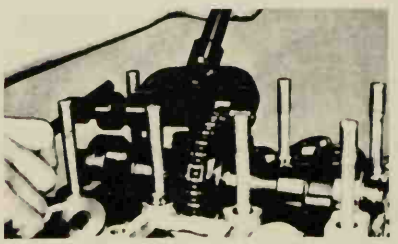
5. Install a new O-ring between the advance unit housing and head cover, and grease the oil seal lip before positioning.

6. Ignition point and advance mechanism housings are identical, but can be installed in only one position.



NOTE: When installing the timing advance mechanism, make sure that the disc face with the arrow showing direction of rotation faces outward. The timing advance mechanism arm with the color mark must be installed in the slot with the color mark next to it.

Cylinder Head



REMOVAL

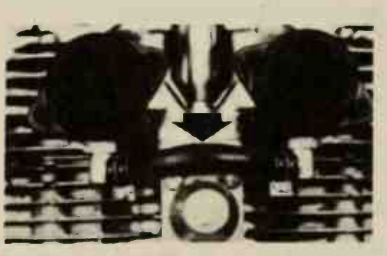
1. Stuff a rag under the cam chain sprocket, then break the link marked with slots and punch holes, using a chain breaker.

NOTE: Before breaking the chain, fasten wire to the links on either side of the marked link, so that the chain won't drop into the case.

The cam chain must be separated at this marked link

Breaking the cam chain

2. Remove the chain, feeding the attaching wire into the case in its place.



3. Remove the camshaft.

4. Remove the camshaft bearings.

5. Remove the carburetor manifolds.

6. Disconnect the manifold equalizer tube.

7. Remove the two attaching bolts under

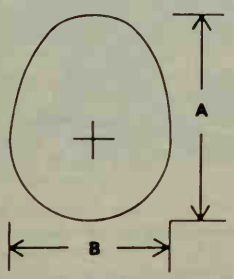
Manifold equalizer tube

the spark plugs and the screw between the intake manifold openings.

8. Lift off the cylinder head, making sure that the cam chain leader wire doesn't drop into the case.

INSPECTION

Cylinder Head



1. Clean any traces of head gasket material from the cylinder head mating surface. Place a straight edge across the mating surface and check for warpage by attempting to slip feeler gauge blades between the head and

straight edge. Standard head warpage is about 0.05 mm (0.002 in.), and maximum allowable warpage is 0.1 mm (0.004 in.). At this point, the head should be milled to restore a flat mating surface.

2. Use a wire brush fitting on a power drill to decarbonize the combustion chambers. The valves should be left in place as this is done, as it minimizes the chance of causing damage to the valve seats.

Camshaft

1. Check the cam lobes for flaking, scoring, or blue discoloration, and replace the

Measure cam lobe height (A) and base circle diameter (B)

cam if any of these signs of damage are present.

2. With a micrometer, measure the height of each cam lobe and compare the measurement with the specifications given below.

3. Measure the base circle of each cam lobe. This measure is taken in a plane perpendicular to the cam height measurement through the camshaft centerline. Refer to the speiifications chart below.

4. Mount the camshaft in a set of v-blocks and measure run-out with a dial gauge. If run-out exceeds 0.03 mm (0.0012 in.), the cam should be replaced.

5. Rotate each of the camshaft bearings slowly noting any roughness, binding, or clicking as this is done. The outer race should rotate smoothly and silently. Try to move the outer race up and down. There should be no movement possible. Make a visual inspection of the bearing balls, noting any denting or blue discoloration.

If any defects are noted in any bearing, replace them as a set.

Valve Assembly

Before removing the valves, check their sealing ability by pouring a small quantity of gasoline into each port and allowing the head to sit for about five minutes. If the valves are properly seating, leakage into the combustion chamber will be minimal.

1. To remove the valves, and install them properly, a suitable C-clamp is necessary. Compress the valve springs and remove the split collars, retainers, springs, seals, and spring seats. Inspect the valves, guides, springs, and valve seats in the following manner. Keep each assembly separate so that every piece can be installed in its original location. New valve seals must always be used on assembly.

2. If considerable mileage has been covered, the valve springs should be replaced as a matter of course. Always replace valve springs as a set.

Measure the free-length of each valve spring with a vernier caliper. If any of the springs is more than 2 mm (0.08 in.) in.) less than the standard free-length given in the specifications chart below, the springs should all be replaced.

Valve Spring Specifications

	Outer	Inner

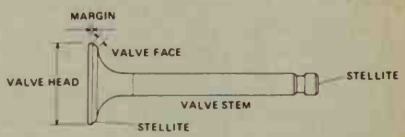
3. Each valve must be free to move up and down in its guide with little resistance. Any sticking or binding as the valve is moved in the guide will indicate that the valve stem or guide is in poor condition.

4. Inspect the valve, paying close attention to the edges of the valve head for pitting, burnt or broken edges, excessive carbon build-up, etc. A certain amount of carbon and lead deposits on the valve face and the top of the exhaust valve are inevitable. Heavy deposits should be carefully scraped off with a dull knife, or a wire wheel, and the valve finished up with very fine emery cloth.

Do not touch the valve seating area during these operations.

If the valve has burnt or broken edges, it must be replaced.



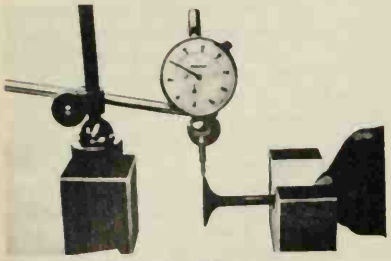
5. Check the end of the valve stem for indented wear caused by the valve adjuster. Although rare, it may occur after long mileage. Since an indentation here will make proper valve adjustments impossible, the valve should be replaced.

NOTE: *The tips and edges of the valves are stellite-coated. Machining for any reason is not recommended. In case of wear, replace the valve.*

6. Carbon deposits should not extend too far up along the valve stem. This would indicate a worn or cracked valve guide.

7. Wet, oily deposits on the back of the valve head is indicative of a worn guide or bad seal. Less severe wear to these components show up as brown oil stains on the valve stem.

8. Holding a valve in your fingers, spin it while observing the head. A wobble is indicative of a bent valve. If a dial gauge is available, check the run-out of the head. Replace the valve if run-out exceeds 0.03 mm (0.0012 in.). Run-out is the total indicated dial gauge reading.



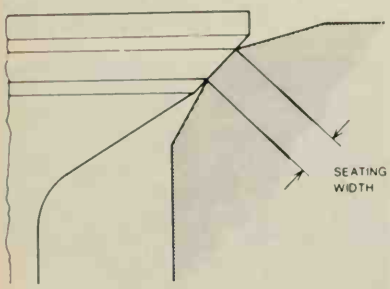
Valve components

Attempt to rotate the valve by hand when it is fully inserted into the guide. If the valve will not rotate easily, or if it sticks as it is turned, it is probably bent.

9. If inside and outside micrometers are available, measure the diameter of each valve stem at three places along the length of the valve, and compare this measurement to the inside diameter of the respective guide, also measure at three places. Subtract the smallest stem diameter obtained from the largest of the guide measurements to obtain the clearance. Compare your clearance to the "Replacement Clearance" given in the following chart:

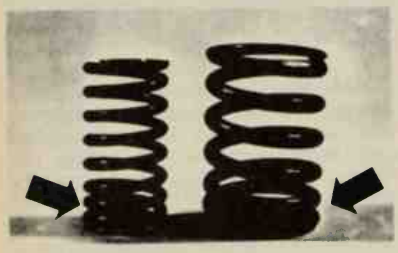
Valve Guide Specifications

			Original Clearance	Clearance Replacement
Intake	Valve Guide ID	8.010–8.019 mm	0.020–0.044 mm	0.100 mm
	Valve Stem OD	7.975–7.790 mm		
Exhaust	Valve Guide ID	8.010–8.019 mm	0.035–0.059 mm	0.120 mm
	Valve Stem OD	7.960–7.975 mm		



Checking valve run-out with a dial gauge

10. To replace a valve guide, heat the cylinder head in an oven to a temperature of 212° F (100° C). Drive out the old guide(s) with a suitable drift. Drive in the new guide(s) until fully seated. Use new O-rings.

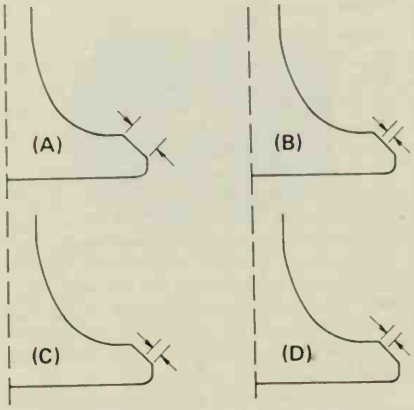


NOTE: *Replacement valve guides are available in two oversizes. The valve guide hole in the cylinder head must be reamed before attempting to install the guide. The reamer diameter should be 15.107–15.115 mm for the first oversize and 15.207–15.215 mm for the second.*

A new valve must always be used when a new guide is fitted.

11. After installing new guides, the valve seat should be recut and the valve lapped in.

Valve seat width measurement point



Valve springs are installed with the close coils (arrows) towards the head

12. Check the width of the valve seat on the valve. It should be about 1.0 mm (0.04 in.) all the way around. If narrower or wider than this, or if width varies around the valve, the seat should be recut and the valve lapped in.

NOTE: *Valve springs are progressively wound. When installing them, be sure they are fitted with the close coils towards the cylinder head.*

SEAT CUTTING

1. Use a machinist's dye to check the width and position of the valve seat. Apply the dye to the valve's beveled seating area and a very small amount of grinding compound to the valve seat in the head. Spin the valve back and forth against the seat for several seconds, then remove the grinding compound and inspect the pattern of the seat, from which the dye will have been removed.

Valve seat patterns (see text for explanation)

2. The valve seat should be about 1.0 mm (0.04 in.) wide and even in width all around the valve. The maximum acceptable seat width is 1.5 mm (0.06 in.).

3. If the seat is uniform in width but is too wide (A), use a flat cutter, then a 30° cutter to reduce the seat width to within specification.

4. If the seat is centered on the valve face, but is too narrow (B), use a 45° cutter to increase the width to the proper specification.

5. If the seat is too narrow, and is towards the top edge of the face (C), first use a flat cutter, and then the 45° cutter.

6. If the seat is too narrow and positioned towards the bottom edge of the face (D), use a 30° cutter first, then a 45° cutter.

LAPPING

1. Valves should be lapped into their seats if the leakage test shows poor sealing, if the seat has been recut, if the valve edges or seat in the head are pitted, if the motorcycle has covered considerable mileage, or if new valves or guides are fitted.

2. Clean off all carbon build-up on the surface of the combustion chamber. Place three small dabs of valve lapping paste around the circumference of the valve head and place the valve into the guide.

3. If you have a lapping tool, use it as the manufacturer directs. Usually the tool will turn the valve back and forth while rotating it around the seat at the same time. Do not use excessive pressure during the operation.

If you do not have such a tool, a piece of thick fuel line placed over the valve stem works just as well. Turn the valve back and forth and rotate it to a new position every few seconds.

NOTE: *Check the condition of the valve face and seat frequently. When a smooth, even finish is evident, stop lapping. Excessive lapping may lead to a pocketed valve.*

4. Remove the valve and clean it thoroughly. Remove any traces of lapping compound from the seat and the combustion chamber. Swab out the guide with a cotton swab soaked in a solvent. Squirt a little oil into the guide so that it may carry away any particles inside.

INSTALLATION

1. Slide all the cam bearings in toward the center, then position the camshaft on the head.

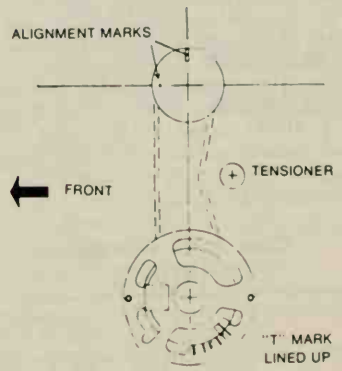
2. Align the camshaft chain sprocket with the crankshaft sprocket by sliding the shaft back and forth. Both bearings must be equidistant in the cam bearing bosses.

3. Install a new cylinder head gasket, pull the cam chain lead wires through the cylinder head and slide the head over the studs. Install and tighten the retaining bolts and screw.

4. Position the pistons at top dead center by lining up the "T" mark as shown.

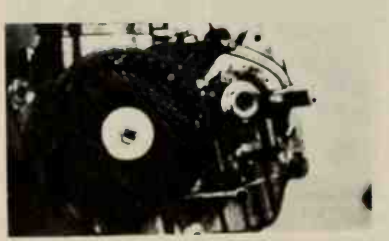
5. Align the camshaft sprocket as shown in the illustration, then draw around and reconnect the cam chain with a new link. Use a chain riveter to secure the new link.

6. Adjust the cam chain tensioner to remove the excess chain slack.



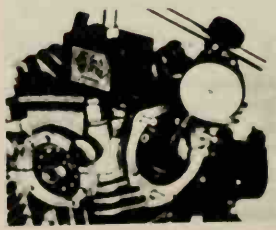
7. Adjust the valves to the correct clearances.

8. Mount a degree wheel to the crankshaft.



9. Insert a wooden dowel pin in a spark plug hole and position the degree wheel to read zero with the piston at top dead center on the compression stroke.

10. Mount a dial indicator over an intake valve adjuster.



11. Rotate the crankshaft counterclockwise and watch when the valve begins to open. The degree wheel should indicate 47° BTDC. If necessary, reposition the cam

chain so that the valve opens at the correct point.

NOTE: *Each chain link equals approximately 10° of crankshaft rotation.*

Cam Chain Tensioner and Vibration Damper

REMOVAL

1. Remove the 4 attaching screws and the vibration damper (see illustration).

NOTE: *Note the position of the two slotted screws.*

Vibration damper screws

2. Remove the attaching bolts and the tensioner housing.
3. Pull out the tensioner unit.

INSTALLATION

Installation is a reversal of the removal procedure. Replace the tensioner housing gasket and apply Yamaha Bond #4 to the mating surfaces.

Cylinder and Piston Removal

1. Lift the cylinder a few inches off its seat and stuff a clean, lint-free rag or rags beneath the pistons. This is to prevent any foreign matter or pieces of broken piston ring from falling into the crankcase when the cylinders are removed.

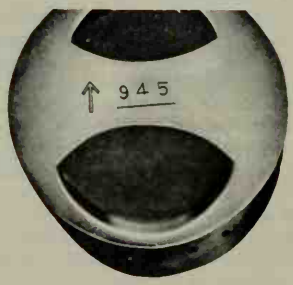
2. Lift the cylinder straight up and free of the studs.
3. With a needle-nosed pliers, remove the wrist pin circlips from the pistons. Push out the piston wrist pins and remove the pistons from the rods.

Support the piston with one hand while pushing out the wrist pin to minimize chances of bending the rod. Push the pin out with steady pressure. Do *not* use an impact method. If the wrist pins resist removal, heat the piston crown gently and evenly with a propane torch until the pins can be easily pushed out.

Discard the wrist pin circlips. New circlips must be used on assembly.

4. Mark each piston so that it can be installed in its original cylinder on reassembly.

Removing the piston wrist pin circlip



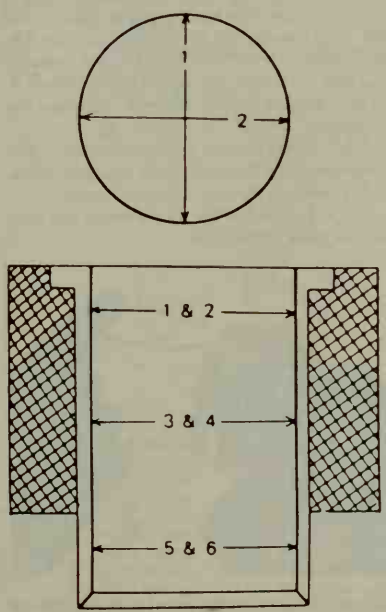
Mark the pistons for position after removal

Inspection

1. Make a visual inspection of the cylinder bore, noting any imperfections. The cylinder walls should be uniformly smooth.
2. With an inside micrometer, measure the diameter of each bore at the top, middle, and bottom. Make measurements in two directions, 90° apart, both parallel and perpendicular to the piston wrist pins.

If the difference between the high and lower measurement in any one direction (taper) is greater than 0.05 mm (0.002 in.), or if the difference between two measurements at any point on the cylinder (out-of-round) exceeds 0.01 mm (0.004 in.), the cylinders should be bored to the next oversize and fitted with new pistons.

3. Make a visual inspection of the pistons. Scoring, scuffing, or seizure marks on the piston skirts may be removed with a fine grade of emery or crocus cloth if they are not too severe. Sanding should be done in a cross-hatch pattern. If the damage is severe (more than about ½ in. wide), the pistons should be replaced.
4. The rings must be free to move in the piston grooves. If they cannot, either they are carbon clogged (which necessitates replacing the rings and cleaning out the grooves), or metal has been pushed into the grooves by a piston seizure. In this event, pistons and rings must be replaced. Carbon-clogged rings are almost always broken when an attempt is made to remove or free them, so be prepared to buy a new set.
5. Pistons are available in four oversizes in increments of 0.25 mm.



Install pistons with the arrow mark on the crown pointing towards the exhaust port. The number indicates size

To determine piston diameter, use a micrometer and measure the diameter in a direction perpendicular to the wrist pin at a point about 11 mm (0.43 in.) above the bottom edge of the skirt.

6. Standard piston-to-cylinder clearance is 0.050–.060 mm (0.0020–0.0024 in.).

Nominal size for the standard pistons is 75 mm. Actual size is obtained by adding the number stamped on the piston crown to 74 mm. Therefore, a piston marked "945" has a diameter of 74.945 mm.

7. Check the condition of the wrist pins. If the pins are blued or show indications of step-wear, they should be replaced. Usually, step-wear can be detected by running a fingernail along the length of the wrist pin. A more conclusive method is to measure the diameter of the pin at three places along its length and compare the readings.
8. Insert each wrist pin into its piston and check for play of the pin in the piston hole. There must be none. The pin must be a fairly tight fit. If the pin is easily inserted and can be turned or moved vertically with no effort, the pistons should be replaced.
9. Lightly oil each wrist pin and insert it into its connecting rod. Check for vertical play. There should be none. If play exists, or if the rod small end is discolored, the rod and/or pin should be replaced.
10. Check the connecting rods for a bent condition. This can be accomplished with two small rectangular blocks of metal of equal thickness. Insert the wrist pins into the rods, and position the pieces of metal beneath them on either side of the rods and resting on the crankcase. Rotate the engine so that the wrist pin rests on the blocks. Both sides of

Cylinder measurement points

Use new cylinder base O-rings upon reassembly

the wrist pin must contact the metal blocks, or the rod is bent and must be replaced.

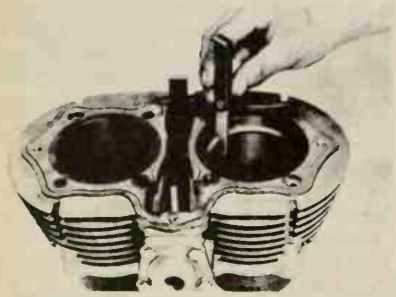
11. Before installation, decarbonize the piston crowns. Remove any carbon from the ring grooves with a piece of broken ring or a very thin screwdriver. Be careful not to scratch the grooves.

Carefully check the cylinder, cleaning the bore thoroughly. If considerable mileage has been covered, honing the cylinders and fitting new rings is recommended. If the cylinders are honed, make a strenuous effort to clean them thoroughly afterwards, preferably with very hot soapy water and a stiff brush. This is to remove any abrasive particles deposited by the hone in the course of the operation.

Remove any traces of gasket material from the cylinder base and the head mating surface.

12. Be sure that all oil passages in the cylinder are clear. Check the condition of the cam chain tensioner guides and replace them if damaged.

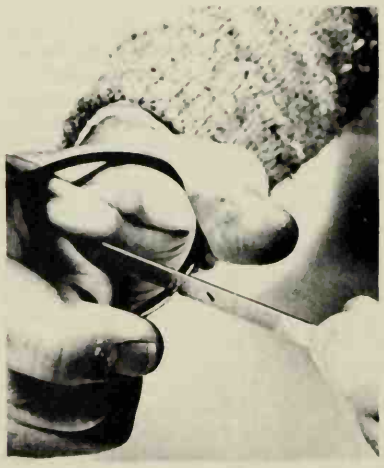
13. Replace the cylinder base O-rings. Check that any O-rings and the important dowel pins fitted to the cylinders are in their proper locations before installation.



Piston Rings

Two checks to be made on the piston rings are side clearance and end-gap. These checks should be made on both new and used rings.

1. Piston ring side clearance for compression rings is checked with the rings installed on the piston. Insert a feeler gauge blade between the ring and the ring groove and check that the clearance is within the specification. Standard clearance is 0.04–0.08 mm (0.0016–0.0032 in.). The service limit is 0.15 mm (0.006 in.). If the clearance is too large, the rings or grooves are worn. If too small, metal may have been pushed into the grooves due to a piston seizure. Check that the grooves are not just carboned up. If new rings do not bring the clearance to the proper value, the pistons must be replaced.



A ring expander reduces the chances of breaking a ring

Checking piston ring end-gap

2. To remove the rings from the piston, use a ring spreader as illustrated. They are available at most auto stores. Decarbonize the ring grooves.

3. To check the ring end-gap, ensure first that the cylinder bore is not excessively worn. Place each ring, in turn, into the bottom of its cylinder and push it in an inch or more using the piston skirt to align the ring in the bore. Measure the end-gap with a feeler gauge. Standard end-gap is 0.2–0.4 mm (0.008–0.016 in.) for the compression rings and 0.3–0.6 mm (0.012–0.024 in.) for the oil rings. The service limit is 0.8 mm (0.032 in.) for the compression rings and 1.0 mm (0.04 in.) for the oil rings. If the end-gap is larger than the service limit, the rings must be replaced. If the measured end-gap of new rings is too large, the cylinder is worn and should be bored to the next oversize.

Filing ring ends

If new rings are fitted and the end-gap is too small, the ring ends must be filed. Hold the ring steady as illustrated, closing the ends over a thin, fine file. Do not squeeze the ring, as this is the easiest way to break it. A few strokes of the file will increase the endgap.

CAUTION: *Do not make more than a few strokes before checking the end-gap again. It is easy to remove too much metal.*

Do not allow the file to slip out of the ring, as this risks breaking it.

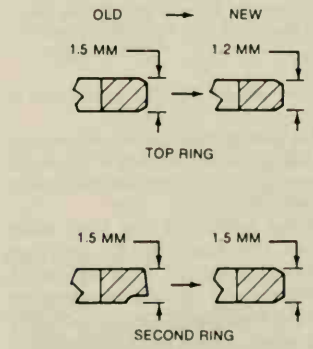
Roll each ring around the piston in its own groove to check for free movement

4. Roll each ring around its own groove and ensure that this can be done easily. If a ring sticks or binds in the groove, the pistons must be replaced.

Cylinder and Piston Installation

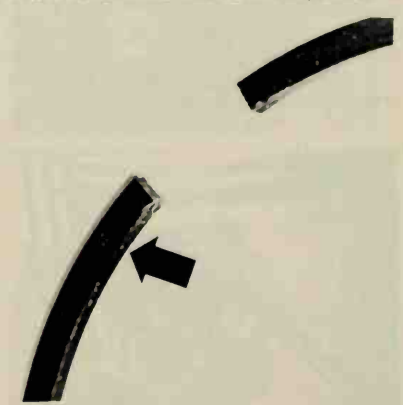
Note that there are differences in the compression rings. The earlier type were used on XS1 and XS2 models and the TX650 to No. 010152. Later TX650s and all XS650 models use the later type ring. Refer to the illustration of ring profiles. The new rings must be used on new type pistons.

1. When installing piston rings, note that all rings are installed with the manufacturer's mark (the small letter near the end-gap) facing *up*.



NOTE: *Oversized rings, which must be used only with the proper oversized piston, are marked as follows:*

Compression Rings

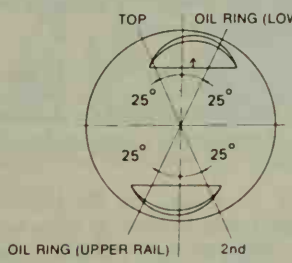


Size (mm)	Mark
Standard	None
Oversize 1st	25
2nd	50
3rd	75
4th	100

Oil Rings

	Size	Color
Standard		Blue (1 mark)
Oversize 1st	25 (0.25 mm)	Blue (2 marks)
2nd	50 (0.50 mm)	Red (1 mark)
3rd	75 (0.75 mm)	Red (2 marks)
4th	100 (1.0 mm)	Yellow (1 mark)

Old and newer model compression ring profiles



Always install rings on the piston with the mark facing up

2. To install the three-piece oil ring, install one rail on the piston below the oil ring groove, fit the expander, then move the rail into place. Install the top rail.

3. Use a ring expander to install the rings to reduce the chance of breaking them.

4. Ring end-gaps must be staggered around the piston so that they do not overlap. Position the end-gaps as shown in the illustration. Note that none of the end-gaps are positioned at the very front or sides of the piston.

Stagger the ring end-gaps around the piston as shown

5. Install the pistons on their connecting rods so that the arrow marks on the crown face the front (exhaust side) of the engine.

NOTE: *Be sure to use new wrist pin circlips.*

6. Slip the wrist pins into place, heating the piston crown as on removal if necessary. Install the wrist pin circlips with a needle-nosed pliers. Be sure each circlip is firmly seated in its groove and arranged so that the circlip end-gap and the cut-out in the piston do *not* align.

7. Lubricate the rings and piston skirts with clean motor oil.

8. Install the O-ring on the oil delivery passage which is around the right rear stud.

9. Install the cylinder base gasket. Check that the cam chain is properly engaged with the crankshaft sprocket.

10. Install the cylinder, routing the cam chain up through its passage as the cylinders are lowered. Compress the piston rings with your fingers as the pistons enter the bores. Be sure the cylinders are firmly seated.

CRANKCASE COVER COMPONENTS

Right Crankcase Cover

REMOVAL AND INSTALLATION

1. Drain the oil. Disconnect the tach cable. Remove the right-side rider's footpeg and the kickstarter crank.

2. Remove the attaching allen screws and the primary case cover.

If the cover resists removal, tap carefully around it with a plastic mallet.

3. Unscrew the tachometer shaft locknut.

4. Drive out the tachometer housing with a hammer and drift.

5. Lift out the tachometer gear.

6. Remove the oil pump (see "Lubrication System.").

7. Remove the oil filter.

8. Installation is the reverse of removal. Make sure that the copper washer is seated under the shaft, and replace the O-ring if it is worn or damaged.

Clutch and Primary Gear

REMOVAL

1. Remove the right crankcase cover as outlined above.

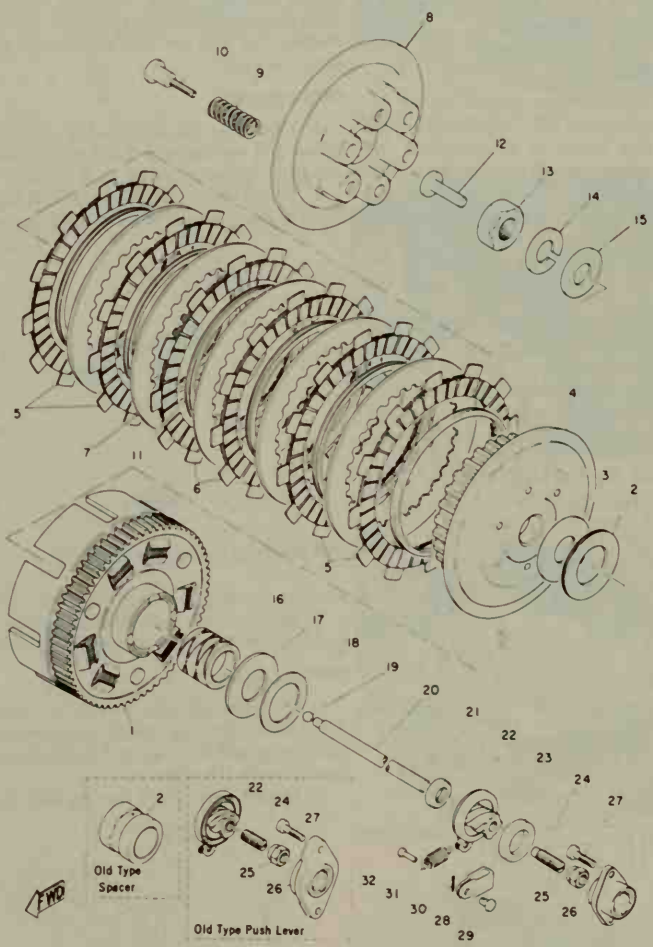
2. Loosen the six clutch spring screws gradually and evenly until they can be removed, then take off the springs and pressure plate.

3. Remove the clutch pushrod, then tilt the unit to the right to remove the pushrod ball. There is another pushrod behind the ball which is more easily removed from the other side of the mainshaft.

4. Remove the clutch friction and steel plates. Keep them in the order in which they are removed.

5. Remove the clutch hub nut. To do this, the clutch hub will have to be locked so that it will not turn. This can be done by engaging a gear and applying the rear brake, or, if the engine is out of the frame, by locking the engine sprocket with a length of chain. An alternative method is to bolt together an old friction plate and steel plate.

6. Remove the clutch hub. Note the two thrust washers and the thrust bearing behind the hub.



7. Remove the clutch housing, clutch bushing spacer and thrust washer(s) behind it. Carefully note the number and location of the thrust washers. They must be installed correctly.

INSPECTION

1. Check the condition of the clutch cover mating surface. Remove any burrs or imperfections with an oilstone.

2. Measure the thickness of the friction plates, and replace them if they are less than 3.1mm (0.12 in.) thick.

3. Place the steel clutch plates on a flat surface, such as a piece of glass, and check for excessive warpage by attempting to slip a feeler gauge blade between the surface and

the plate. Replace the steel and friction plates as a set if warpage exceeds 0.2 mm (0.008 in).

4. Measure the free-length of each clutch spring and replace them as a set if any are found to be less than 33.6 mm (1.32 in.) long, or if their length varies. If the latter is true, be sure that all of the screws are evenly tightened on assembly.

5. Check the friction plate tabs for wear or damage. Check the clutch housing for indented wear caused by the tabs. Remove any burrs with a file or oilstone.

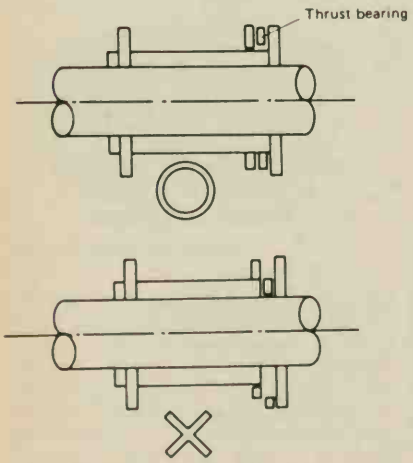
6. Check the corresponding splines of the clutch hub and steel plates for indented wear.

7. Using a dial indicator, check the pushrod for a bent condition. Replace the pushrod if it is bent more than 0.2 mm (0.008 in.).

8. Check the condition of the clutch gear teeth. Note any pitting or chipping. Check the primary gear teeth as well. If damage to either is noted, replace both. The primary gear is replaced by removing the securing bolt and pulling off the gear.

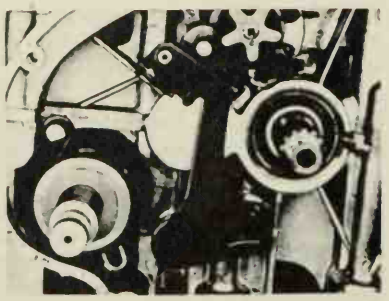
INSTALLATION

1. If the primary gear was removed, be sure that the securing nut is tightened to 85 ft lbs. The gear is keyed to the crankshaft. Be sure that the key is in place before fitting the gear to the shaft.



2. Install the thrust washers and spacer, followed by the clutch housing.

3. Use some heavy grease to hold the thrust bearing and washer, then install the clutch hub.



Tighten the clutch hub to 54–58 ft lbs.

4. Friction plates are alternated with steel plates in the housing. There are two kinds of friction plate—fiber-backed (4) or alloy-backed (2). The fiber-backed plates are installed first. A friction plate is fitted to the housing first, then a steel plate, and so on. After the four fiber-backed plates are used, install the alloy-backed plates, alternating them with the steel plates as before.

5. Fit the clutch pushrod ball, the pushrod, and the pressure plate. Install the clutch springs and screws. Tighten the screws gradually and evenly until all are secured.

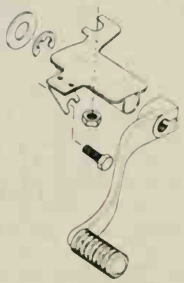
Shift mechanism

Gearshift Mechanism

REMOVAL

1. Remove the right crankcase cover. Remove the clutch assembly.



2. Remove the left crankcase cover, shift lever and footpeg.

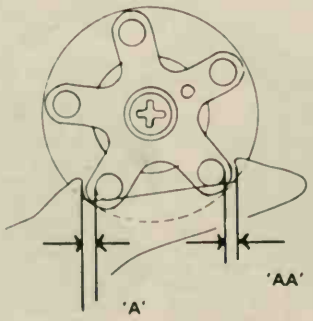
3. Remove the chain guide nut, wire clamp and the guide. Remove the circlip from the gearshift shaft on the left side of the engine and pull out the gearshift assembly from the right.

INSPECTION

1. Check the gearshift shaft for a bent condition and replace it if it is bent. Check the condition of the gearshift shaft splines.

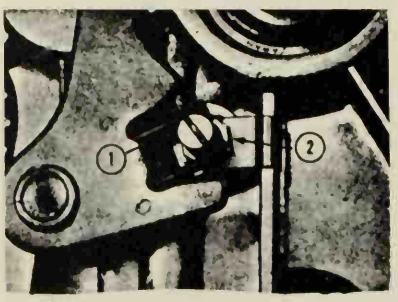
2. Check the condition of the shift fingers. Note any chipping or wear to the finger ends.

Shift lever and chain guide assembly



Replace the fingers if they are bent or worn.

3. Inspect the shift mechanism springs and replace them if weakened or broken.



INSTALLATION

1. Installation is the reverse of removal. After fitting the mechanism, temporarily install the gearshift lever and test shifting action through the gears.

2. In each gear, check that the shift fingers

are equidistant from the shift drum pins. Refer to the illustration. If they are not, loosen the adjusting screw locknut and turn the screw to equalize the distances. Do not forget to tighten the locknut and bend up the locktab.

3. Check for freeplay in the gearshift lever. There should be none. If any is evident, the return spring is evidently weakened and should be replaced.

Kickstarter Shaft

REMOVAL

1. After removing the right crankcase cover, the kickstarter shaft can be removed by pulling it out.

2. When disassembling the shaft components, lay each one out in the order removed to facilitate assembly.

INSPECTION

1. Check the condition of the kickstarter shaft splines.

Be sure that the kickstarter return spring is hooked over the boss as shown

2. Check the kickstarter gear teeth for chipping or other damage, and replace it if such damage is noted.

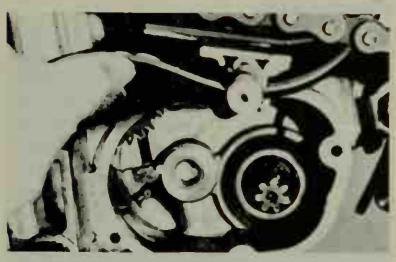
3. Check the condition of the shaft return spring. The spring should be replaced if it will not return the shaft quickly to the rest position and hold it securely in place.

INSTALLATION

1. Set the kickstarter gear clip into the groove in the crankcase.

2. Rotate the return spring clockwise and hook it onto the projection.

Starter Reduction Gears



REMOVAL

1. Drain the engine oil.

2. Remove the left and right crankcase covers.

3. Remove the gear train cover.

4. Remove the idler gear.
5. Remove the clutch.
6. Remove the stopper plate.
7. Remove the outer gear ("2" in the illustration), then the gear circlip and the other reduction gears.

Starter reduction gear train compartment

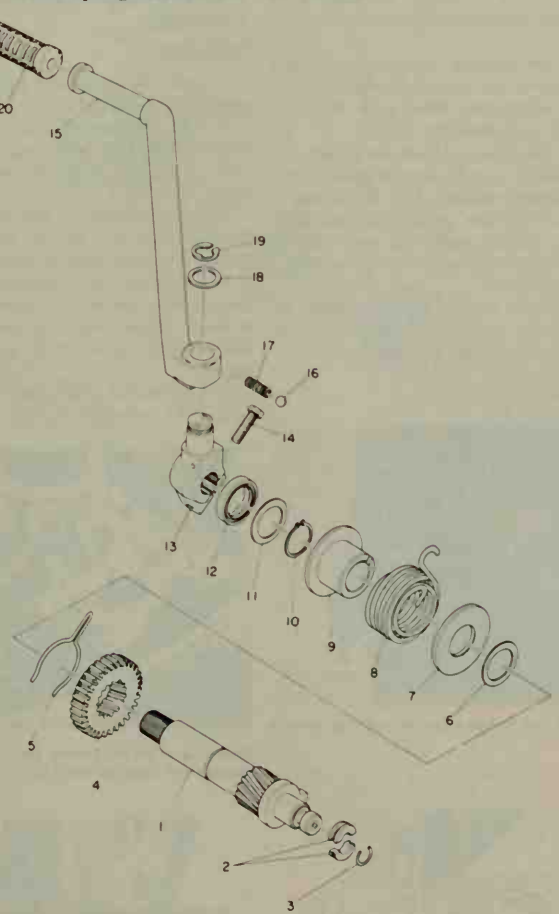
INSPECTION

1. Check all the gear teeth for wear, pitting, or broken teeth, and replace any if necessary.
2. Check the return spring tension, and replace it if it is fatigued, weakened, or broken.

INSTALLATION

Installation is the reverse of removal. Be sure that the starter clip is firmly seated in the crankcase groove. Use a non-permanent thread-locking compound on the stopper plate screw.

Left Crankcase Cover



The cover is easily removed after removing the left footpeg mounting bolts, the gearshift lever, and the cover securing screws. It is not necessary to drain the oil from the crankcase.

Alternator

For alternator output tests, refer to "Electrical System," chapter 7.

REMOVAL

1. Remove the left crankcase cover.
2. Remove the two stator securing screws. Carefully remove the stator assembly, being careful that the wires are not ripped during the process.

Removing the rotor

3. To remove the rotor, a special puller is needed. Remove the rotor securing nut and washer. Fit the special tool, and remove the rotor.

4. Remove the woodruff key from the crankshaft.

INSTALLATION

1. Installation is the reverse of removal. Lightly grease the rotor woodruff key and install it in its seat on the crankshaft. Be sure that the key is fully seated before attempting to install the rotor.

2. Lightly grease the crankshaft taper. Line up the rotor slot with the key and push the rotor on as far as possible by hand. Tightening the rotor nut will seat the rotor fully.

CAUTION: *Do not tap the rotor into place with a hammer or other instrument as damage may result.*

3. Tighten the rotor nut 50–54 ft lbs.

Engine Sprocket

REMOVAL

1. Remove the left-side rider's footpeg. Remove the gearshift lever.

2. Remove the left side crankcase cover screws and take off the cover.

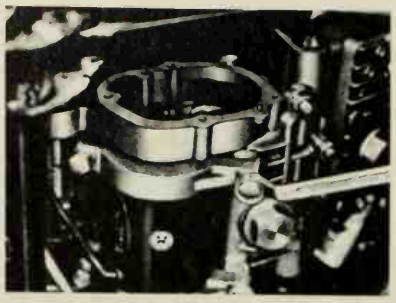
3. Place the transmission in gear and apply the rear brake. Unscrew and remove the engine sprocket nut. Remove the lockwasher and sprocket. It may be necessary to move the rear wheel forward to remove the sprocket from its shaft.

INSTALLATION

Installation is the reverse of removal. Tighten the sprocket nut to 72–87 ft lbs.

Bend up the locktabs over one of the nut flats.

LOWER END AND TRANSMISSION



Splitting the Crankcases

Splitting the crankcases is necessary for service to the crankshaft and connecting rods, transmission gears, and internal shift mechanism.

Removal of the engine is required.

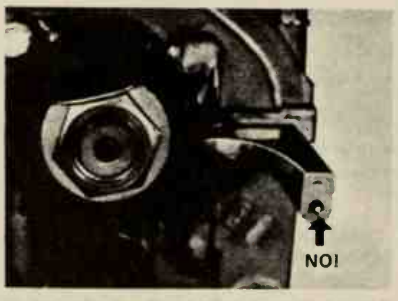
All top end components (cylinder head, cylinders, pistons) must be removed in order to split the cases. When disassembly is complete, the top half of the crankcase will lift off, the crankshaft and transmission gears remaining in the lower case half.

1. Drain the engine oil. Degrease the engine as thoroughly as possible, especially the lower crankcase half area. This will to some extent prevent foreign matter from entering the engine when it is disassembled.

Removing the starter motor

2. Remove the engine from the frame.

3. Remove the top end components.



4. Remove the left and right crankcase covers and the components therein: clutch, primary drive gear, kickstarter shaft assembly, gearshift mechanism, engine sprocket, alternator stator and rotor, starter drive reduction gears on electric start models, etc.

5. Remove the electric starter motor, if fitted.

6. Turn the engine upside down and loosen the crankcase nuts and bolts. The fasteners are numbered. Start with #18 and loosen them in descending order.

7. When the nuts and bolts have been removed, carefully turn the engine upright and lift off the upper crankcase half. If the case is stuck, tap around the mating surfaces very gently with a plastic mallet. Be sure that all fasteners have been removed before attempting to split the cases.

CAUTION: *Do not use a steel hammer to do this, and do not strike the left crankcase cover mounting flange (see illustration).*

Do not strike this flange when attempting to split the cases

Case Assembly

1. Be sure that the crankcase mating surface is clean and free of all traces of old gasket compound. Minor scratches or burrs can be removed with an oilstone, although care must be taken that the surface is not grooved when doing this.

2. Lubricate all bearing surfaces with motor oil.

3. Be sure that the crankshaft and transmission shafts are properly seated. The transmission shaft bearings are located with set rings. Be sure the shift forks are engaged with their gears.

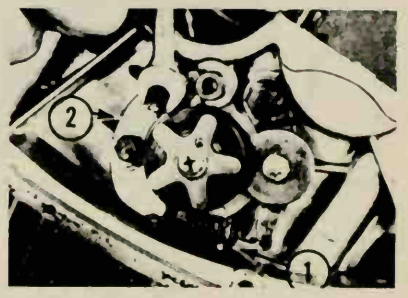
4. Be sure that all dowel pins between the cases are in place.

5. Apply a thin coat of a liquid gasket compound to the case mating surface. Install the upper case half. After ensuring that it is properly seated, install the crankcase bolts and nuts and tighten them gradually and in a cross pattern.

Tighten the 8 mm bolts and nuts to 15–17 ft lbs.

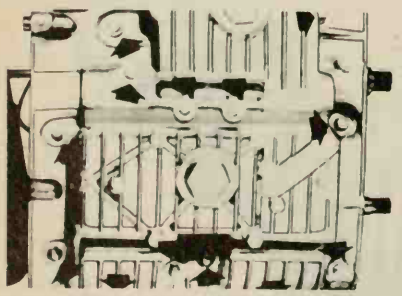
Transmission/Gear Shift Assembly

REMOVAL



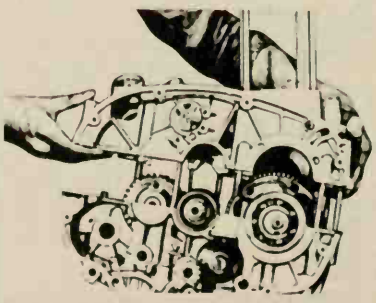
1. Split the crankcases as described in the preceding section.

2. Lift the transmission shafts and gear clusters out of the lower case, tapping lightly with a plastic mallet if necessary to free them.



3. Before removing the shift forks, mark them so that they can be installed in their proper locations without confusion later.

4. Check for free movement of the shift drum before removal. If movement is rough or balky, inspect the shift drum and/or shift fork shaft for grooves or wear after disassembly.



5. Disconnect the shift drum stopper spring (#1 in the illustration), bend down the

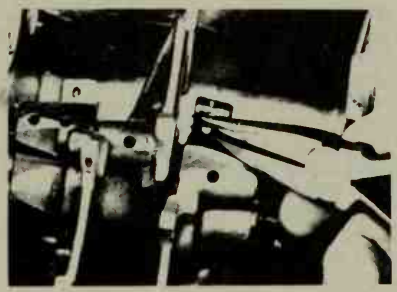
locktabs and remove the locating plate bolts and the locating plate (#2).

6. Remove the shift fork shaft.



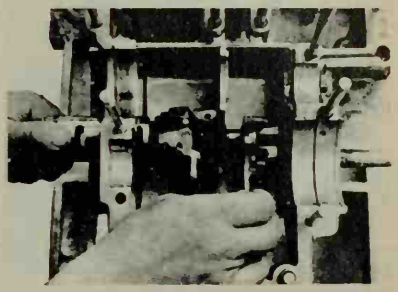
7. Unscrew and remove the neutral stopper bolt and plunger assembly from the crankcase.

Neutral stopper bolt

8. Remove the cotter pin on each shift fork, and take out the cam follower roller.

9. Pull out the shift drum, being careful not to lose the cam follower rollers.

Removing the shift fork roller pins

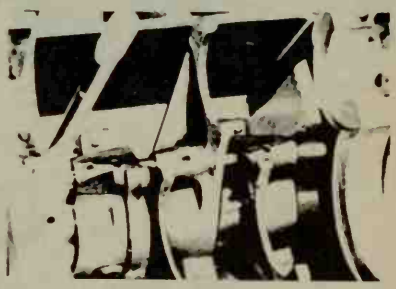


INSTALLATION

1. If the gears have been removed from their shafts, install them in the correct locations, referring to the illustration of the transmission assembly if necessary. Note that *new* transmission shaft circlips must always be used.

2. Lubricate the shift drum and fit it to the crankcase sliding it through the shift forks. Be sure that the shift forks are correctly installed. The fifth gear shift fork has a notch matched into it for the neutral light switch. The fourth gear fork is also notched to provide clearance for the neutral stopper. Use new cotter pins. Be sure that the cam follower rollers are in place.

3. When installng the shift drum locating plate bolts, use a non-permanent thread-locking compound on the threads. Bend up the locktabs against the flats of the bolt heads.



4. Turn the shift drum so that it is in the neutral position, and install the shift drum stopper plunger and bolt assembly.

5. Install the transmission shaft assembly into the upper case half.

The use of new oil seals is important.

6. When fitting the transmission shafts to the crankcase, be sure that they are properly seated and that the bearing locating rings are in place. Do not attempt to force the shafts into place. The shift fork fingers must engage their gears.

7. Lubricate the gears and shaft bearings with clean motor oil.

8. After installation is completed, check for smooth shifting throughout the range.

Crankshaft

REMOVAL

1. Split the crankcases as outlined above.

2. Carefully lift out the crankshaft, tapping upwards on the end of the shaft with a plastic mallet to free the crankshaft if necessary.

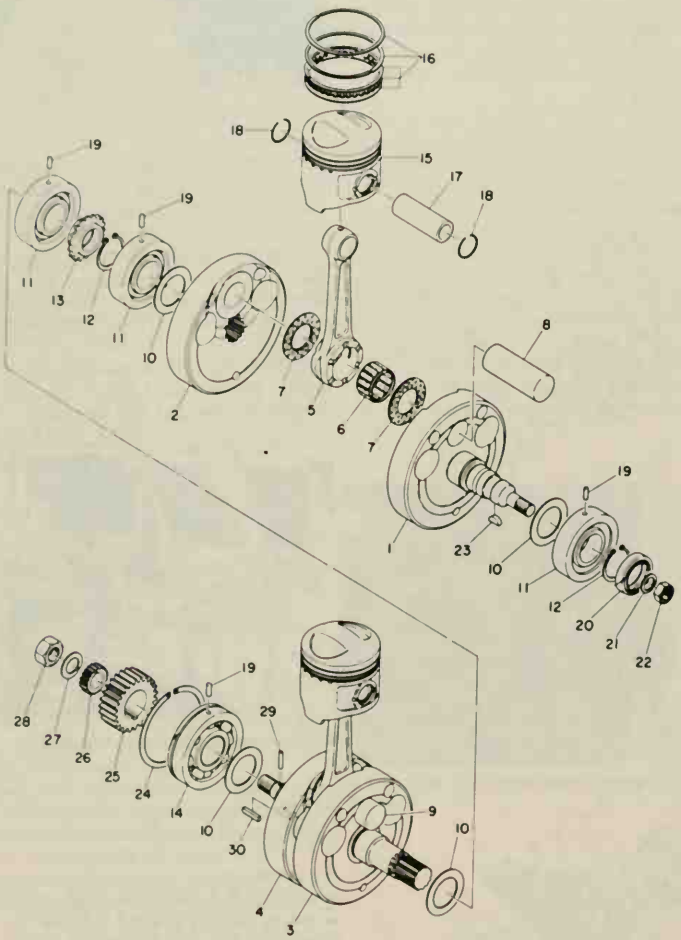
INSPECTION

1. Check each of the crankshaft bearings for wear. Oil the bearings with motor oil, then turn the outer race slowly. Movement must be smooth, effortless, and noiseless. If the rotation of any of the bearings is halting, or if clicking noises or binding is noted, the bearings should be replaced.

Bearings should always be replaced as a set, and disassembly of the pressed-together crankshaft is necessary to remove the inner bearings.

This operation requires a great deal of special equipment and must be left to a trained expert.

2. Check each bearing for visible damage to the bearing balls such as denting or blue discoloration due to heat damage. Replace the bearings if either of these conditions is present.



3. Mount the crankshaft assembly in a pair of v-blocks and check the run-out at a point just outboard of the outer bearings with a dial indicator. Run-out should not exceed 0.03 mm (0.0012 in.). If it does, the crank is bent and must be replaced.

4. With a dial gauge, measure the total amount of lateral movement (back and forth) in the connecting rod small end. Be sure to hold the big end steady to obtain an accurate reading. The maximum amount of small end movement allowable is 2 mm (0.08 in.). If this side play exceeds this specification, it is probable that the big end bearings are worn. Disassembly of the crankshaft is required for replacement.

5. Use a feeler gauge to measure con rod big end side clearance. Standard clearance is 0.30–0.36 mm (0.012–0.024 in.). Replace the rods and bearings if the side clearance exceeds 0.26 mm (0.010 in.).

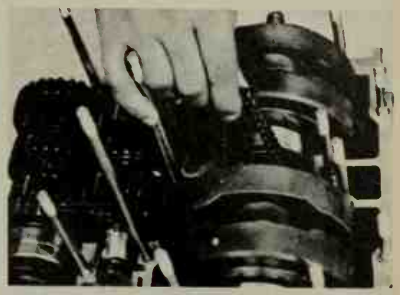
6. Lightly oil the connecting rod big end bearings and rotate the rod slowly around the crankpin. Movement must be firm and smooth with no noticeable roughness, binding, or noise. If any of these conditions are noted, the big end bearings are probably in need of replacement.

7. Using a dial gauge, check the amount of connecting rod radial movement (up and down) on the crankpin. Movement should be almost nil. If any appreciable movement is noted, the big end bearings may be worn to the point of replacement.

INSTALLATION

1. Use an oil can to flush out all of the bearings by squirting clean motor oil into the races. Check for free movement of all bear-



Crank bearings must be seated by means of the locating pins (arrows)

ings before installation. Sometimes foreign matter will get into a ball bearing race and cause binding. Be sure that there is none of this.

2. Use a new seal on the left side of the crankshaft, installing it so that the teflon lip faces outwards.

3. Position the crankshaft over the case, and carefully lower it into place so that the cam chain does not drop down and get caught beneath the crank.

4. Each of the crank bearings is located by a pin fitted to the crankcase. The bearing outer races are marked to facilitate installation. Line up the punch mark on each bearing outer race with the crankcase mating surface and lower the crankshaft into position. Be sure that each locating pin enters the hole in each bearing race. Do not attempt to force the crank into place. If it will not seat, turn each bearing race slowly a few degrees in either direction until the locating pin enters the hole in the bearing.

Be sure the cam chain is properly engaged on the drive sprocket

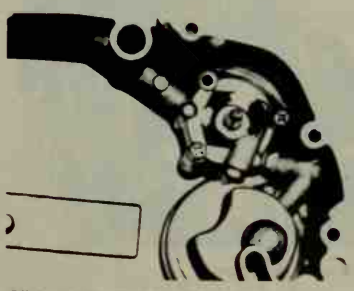
Removal

1. Remove the tachometer shaft locknut, then drive out the tachometer housing with a punch.



2. Remove the tachometer gear, washer, and O-ring.

3. Remove the oil pump gear and woodruff key.

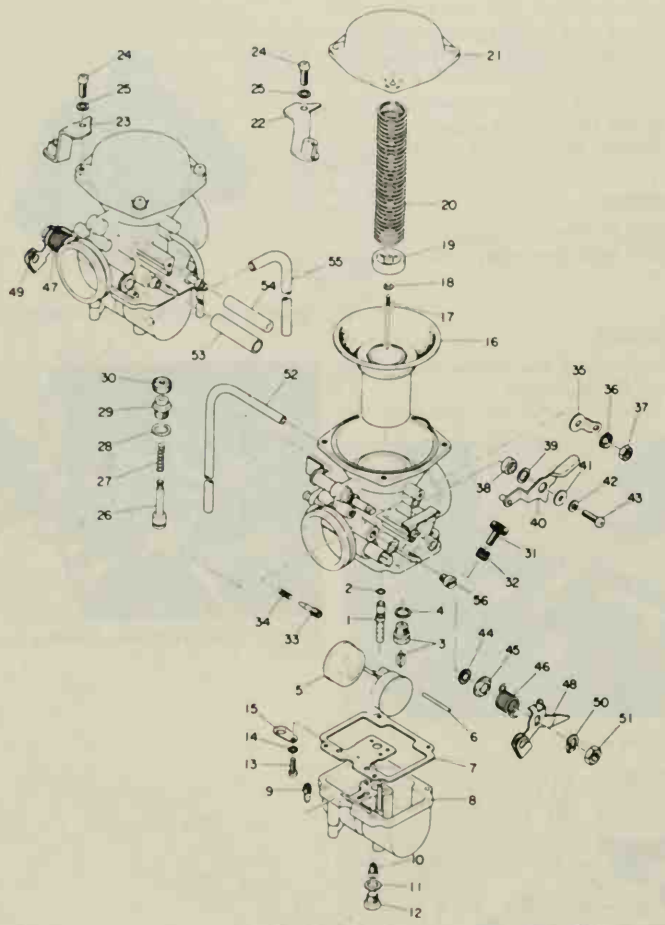
FUEL SYSTEM

CARBURETORS



Removal

1. Disconnect the fuel line(s) from the petcock(s) after first ensuring that they are set to the "off" position.
2. Raise the seat and remove the gas tank mounting bolt. Disconnect the gas tank balance tube, if so equipped, and remove the gas tank.
3. Remove the side covers.
4. Disconnect the throttle cables from the carburetors.
5. Remove the air cleaner housing mounting bolts. Loosen the air cleaner-to-carburetor clamp screws.
6. Remove the balance tube between the carburetors from one of the float bowls.
7. Loosen the manifold clamp screws and remove the carburetors from the motorcycle. On late models, the carburetors are connected by a piece of angle iron and they must be removed together.

Installation

Installation is the reverse of removal. Be sure that both carburetors are firmly seated in their manifolds and are vertically positioned before tightening the clamp screws. If the units have been disassembled, turn on the petcock(s) and check for fuel leaks before operating the motorcycle.

Be sure that all fuel lines are properly secured with safety clips.

Disassembly

1. Remove the 4 screws which secure the vacuum chamber cover, take off the cover, lift out the spring.
2. Carefully disengage the diaphragm from the carburetor body, and pull the slide assembly straight out.
3. Remove the needle retainer and the needle.
4. Remove the float bowl screws, and take off the float bowl.
5. Remove the float pivot pin, take away the float assembly, and the float needle.
6. Unscrew the main jet. Pull out the needle jet.
7. Remove the pilot jet.

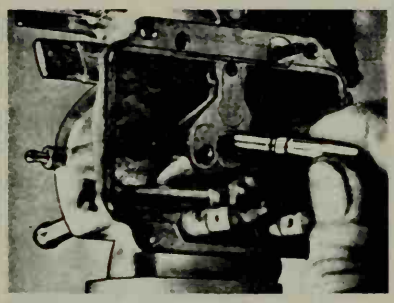
Assembly

Assembly is basically the reverse of the disassembly procedure. Note the following points:



1. Always use new gaskets and O-rings.
2. Exercise care when installing jets—they are made of soft brass and are easily damaged if overtightened.
3. If the throttle slide and needle have

been disassembled, first check that both needle clips are installed in the third groove from the top on XS650 C-F models, and the fourth groove on all others.

4. When installing the pilot screws, turn them in gently until they are lightly seated, then back them out the proper number of turns as given in the "Tune-Up Specifications" chart at the end of chapter 3. Be sure to fit the idle limiter caps if so equipped.

5. When fitting the throttle slide, be sure to engage the tab on the diaphragm with the cut-out on the carburetor body.

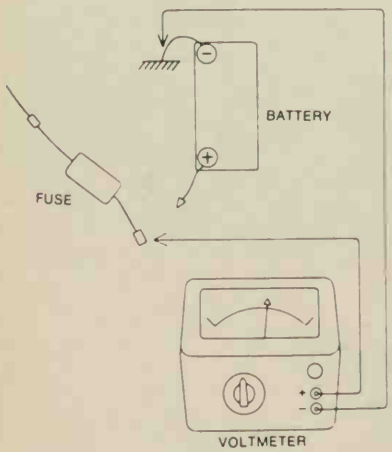
6. Check the float level as outlined in chapter 3.

Be sure that the diaphragm tab is properly seated

ELECTRICAL SYSTEM

CHARGING SYSTEM

CAUTION: *The following precautions should be taken when carrying out electrical system tests.*



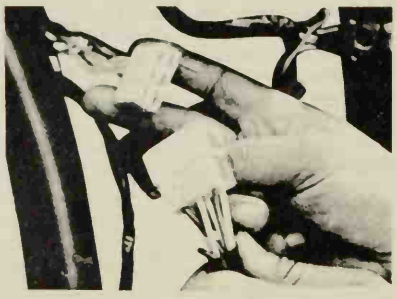
1. Be positive that the battery connections are not reversed. This will burn out the rectifier almost immediately.
2. Be certain all electrical connections are noted before disconnecting them so that they can be reconnected properly.
3. Do not run the engine at high rpm with the "P" terminal circuit of the rectifier disconnected.
4. When quick-charging the battery, always disconnect the rectifier at the "P" terminal.
5. Never disconnect the battery while the engine is running.
6. When testing the regulator, be sure to keep the battery connected.
7. When testing the regulator, be sure that the battery has a full charge.

Alternator

OUTPUT CHECK

NOTE: *To give accurate results, the battery must be in good condition and fully charged before performing the output test.*

1. Connect a D.C. voltmeter across the battery terminals.



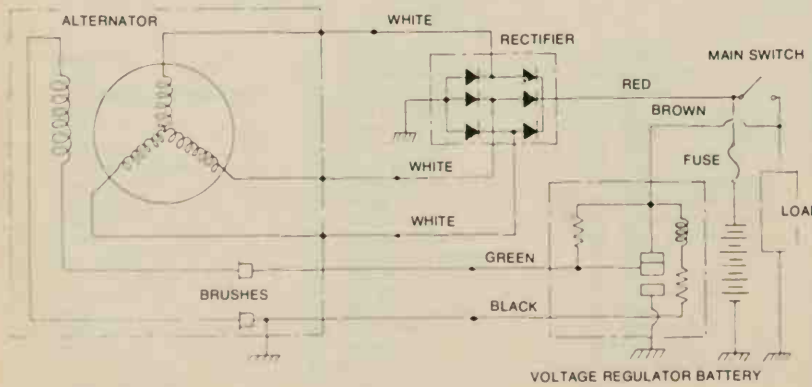
Alternator output test connections

2. Start the engine and let it run at about 2,000 or more rpm.
3. Battery voltage on the meter should be 14.5 v with a maximum allowable variation of 0.3 v.
4. If the voltage is greater than this, check the voltage regulator (see below). If it is less, check the alternator wiring, the regulator, and the rectifier.

CAUTION: *Never run the engine with the battery leads disconnected. To do so risks ruining the other charging system components.*

FIELD COIL/ARMATURE CHECKS

1. Disconnect the alternator wiring at the plastic connector.
2. There are six wires joined at the connector. Note the following tests.



Disconnecting the alternator wiring

Checking armature continuity

3. Connect ohmmeter leads across the white wires. Do two wires at a time. If the wires are lettered "A", "B", and "C", readings are taken across A–B, A–C, and B–C. In all cases, resistance should be 0.8–1.0 ohms.

Charging circuit

4. Adjust the ohmmeter scale to the highest range and attach one meter lead to the stator housing and the other to each white wire, one at a time.

In each case, the resistance should be infinite.

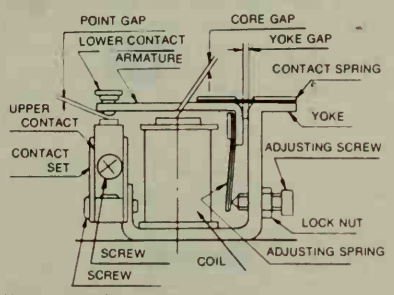
5. If resistance readings vary from the above, the entire alternator stator winding assembly must be replaced.
6. Visually inspect the condition of the carbon brushes for wear or flaking. Brush length (new) is 14.5 mm (0.57 in.). Replace the brushes if they are shorter than 7.0 mm (0.28 in.).
7. The carbon brushes are connected to the black and green alternator wires. After disconnecting the alternator wires at the plastic junction, check the resistance between the green wire and the carbon brush and then the black wire and its carbon brush. In both cases resistance should equal zero ohms, or the wire(s) will have to be replaced.

Checking slip ring resistance

Checking slip ring to rotor core resistance

8. Check the resistance between the slip rings. Resistance should be 5–7 ohms. Note that both slip rings must be clean for an accurate reading. Clean them with an electrical contact cleaner if necessary.
9. Using the ohmmeter's highest scale, measure the resistance between each slip ring and the rotor core. Resistance must be infinite.
10. If readings vary from those above, the field coil winding should be replaced.

Voltage Regulator



The voltage regulator is reached by removing the right side cover.

A mechanical voltage regulator is used on all models. The regulator is adjustable, although this procedure should not be undertaken until the alternator has first been inspected for faults.

1. Disconnect the red wire at the fuse box (as above), start the engine, and hook up the voltmeter positive lead to the red wire.

Ground the voltmeter negative lead. Voltage reading should be 14.5–15v. If voltage is either too low or too high, proceed as described below.

2. Remove the regulator housing. Note

Voltage regulator components

the adjusting screw which bears on a flat spring steel plate.

3. Turn the screw in or out to adjust the voltage to the proper value. Turning the screw IN raises the charging voltage, while turning the screw OUT decreases the charging voltage.

4. If this does not bring the charging voltage to within specification, make a visual inspection of the regulator. Note any pitting of the contact points. Be sure that the points are not stuck together. Replace the regulator as necessary.

5. For further tests, make sure that the engine and electrical system are off. Disconnect the regulator wires at the plastic connector junction.

6. Attach an ohmmeter to the black regulator wire and to the regulator base (ground). It should read zero resistance.

7. Attach the ohmmeter leads to the brown and green regulator leads. Remove the regulator housing if this has not already been done.

8. Move the central contact point as indicated below and note the readings.

a. When the central contact point is held against the top point, resistance should be zero.

b. When the central contact point is midway between the top and bottom points, resistance should be 9–10 ohms.

c. When the central point is held against the bottom point, resistance should be 7–8 ohms.

9. Connect the ohmmeter leads across the black and brown regulator wires. Hold the central point against the top point. Resistance should be 36–38 ohms.

If any of the readings vary from these figures, and the cause is not dirty points and broken or frayed wires, the regulator should be replaced.

Rectifier

1. The rectifier consists of a six-diode "bridge." A diode will allow current to pass in one direction only. If any diode allows current to pass in both directions, or in neither direction, the operation of the entire unit will be upset and the rectifier will have to be replaced.

2. It is the ability of the diodes to pass current one way and stop it in the other which is tested when checking the rectifier.

3. The rectifier can be checked with an ohmmeter or a self-powered low-voltage test light. Disconnect the rectifier wiring and remove it from the motorcycle.

4. Connect the positive lead of the tester to the rectifier red lead and the negative tester lead to each of the three white leads in turn. Note whether or not there is continuity in each case. Now reverse the tester connections so that the negative tester lead is connected to the red rectifier lead and the positive tester lead is connected to each white lead in turn. Note whether or not there is continuity.

If there was continuity for a certain connection during the first test, there should not be any when the tester leads are reversed. If there was continuity in both cases, or lack of continuity in both cases, a diode is defective and the rectifier must be replaced.

5. Connect the positive lead of the tester to the rectifier black lead and the negative tester lead to each of the three white leads in turn. Repeat the test with these connections. Replace the rectifier if all tests are not satisfactory.

IGNITION SYSTEM

Breaker Point Ignition

1. In the event of failure of the ignition system, first check the fuses; if all are in working order, check that the snap connectors for the coils and breaker points are all clean and tight.

2. At this point refer to "General Information" for inspection procedures for the breaker points, plugs, and battery. If these items are all in working order, the problem may be isolated to the coils, condensers, or plug caps.

3. If only one cylinder fails to fire, and the problem is not a loose connection or defective spark plug, suspect the plug cap. The caps are fitted with a resistor to prevent radio interference while in operation, and heat and vibration may cause the value of this resistor to increase considerably, even to becoming an open circuit.

The easiest way to see if a misfire is due to a defective cap is to switch the plug cap of the non-firing cylinder with the other cap. If the dead cylinder begins to fire and the other cylinder ceases, the problem is the plug cap. The caps should be replaced as a set.

Functional caps will have a resistance of 9,000 ohms. Usually, when resistance exceeds this value significantly, the plug for that cap will no longer fire.

Caps are easily removable by unscrewing them from their cables.

4. Defective condensers are seldom a problem, since these are now usually replaced along with the breaker points. Defective condensers will cause considerable arcing or sparking between the breaker point contacts while the machine is running, and this should be cause for replacement before they fail completely. Badly burned or pitted point contact surfaces can also be caused by defective condensers, as well as by improper adjustment. If the points are in bad condition, replace them and the condensers as well.

5. Condenser capacity can be checked with electrical test equipment (if available) in place on the machine, provided the condenser is first disconnected from the primary terminal. Capacitance should be 0.24 MFD. The resistance of the condensers should be in excess of 3 MΩ. A variation of 10% in either reading is allowable.

6. If the condensers are not suspect, check the ignition coils. Coils should be checked for continuity of the windings. First remove the gas tank. Disconnect the red/white coil lead and the other lead which is orange for the left cylinder's coil, or grey for the right. Check resistance across the leads. It should be about 4 ohms. If the resistance is not very close to this figure, the primary winding is defective and the coil must be replaced.

7. To check the secondary coil, first remove the spark plug cap from the plug lead. Check the resistance between the plug lead and the orange or grey lead. Secondary winding resistance should be 9.5 K ohms. If the measured resistance is not very close to this value, the secondary winding is breaking down, and the coil must be replaced.

TCI

1. In the event of spark failure, first check the entire electrical system for loose connections.

2. Check that the battery is fully charged. Recharge if necessary.

3. Check all fuses.

4. If all of the above elements are found satisfactory, check the resistance of the ignition coil primary and secondary windings. Primary winding resistance should be about 3 ohms. Secondary winding resistance should be about 8.6 K ohms.

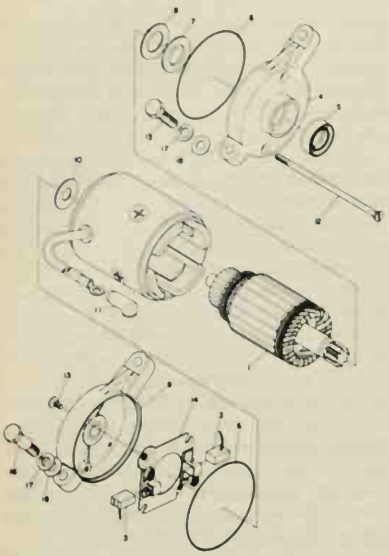
5. Check the pick-up coils' resistance. It should be about 700 plus/minus 150 ohms.

6. If all of the above elements are satisfactory, replace the TCI unit.

STARTING SYSTEM

Testing

If the starter will not operate, switch on the headlight and observe its intensity. If it is dim when the starter is not being operated, check the battery connections and recharge the battery. If the headlight doesn't light, check the fuse, the battery connections, the ignition switch and its connections, and check the continuity of the wire between the ignition switch and the battery.



If the headlight is normally bright, press the starter button and observe any changes. If the headlight dims when the button is pushed, it indicates that the starter motor is drawing current. If it does not dim (i.e. nothing happens), the starter motor is probably not getting any current. In this case, suspect the starter solenoid.

To check the solenoid and starter button, the easiest test is to bypass the unit completely by disconnecting the battery lead from the solenoid and connecting it directly (with the aid of a high-tension jumper cable) to the starter motor terminal. If the starter motor works, the solenoid or starter button is defective and must be replaced.

If the motor still fails to work, the motor itself may be the cause of the trouble.

Starter motor faults are rare, but several things can go wrong.

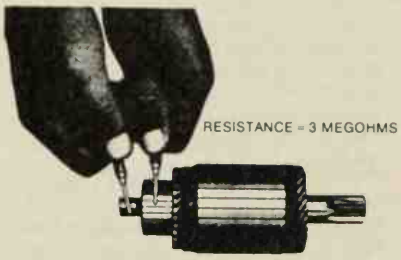
doesn't turn over, suspect the starter motor clutch.

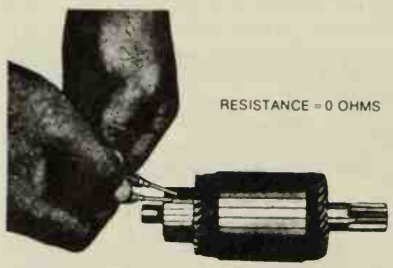
If the engine will turn over only very slowly and without a great degree of predictability, some possible causes include: a low or almost dead battery, oil which is too thick for weather conditions (extreme cold), or bad bearings in the motor itself. Worn bearings could cause the armature to contact the field coils which will effectively short out the starter. Usually, repeated attempts at starting will result in the starter motor getting very hot. Other possible causes of starter motor trouble include worn brushes, a worn or dirty commutator, or a defective armature.

Starter Motor Service



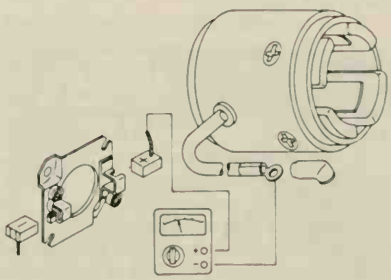
REMOVAL AND INSTALLATION

The starter motor is bolted to the underside of the crankcase.



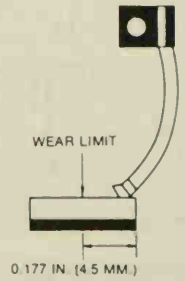
1. Drain the engine oil.
2. Remove the four 8 mm starter motor mounting bolts. Pull the starter motor straight back to remove it.
3. When refitting the starter motor, be sure that the gear shaft properly engages the reduction gear.
4. Tighten the mounting bolts to 15 ft lbs.
5. Fill the crankcase with oil.

INSPECTION

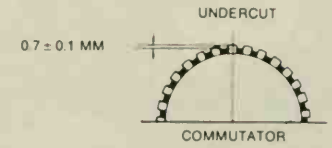


1. Take out the two screws and remove the starter side cover.
2. Check electrical continuity between the commutator and armature core using a multitester or test light and battery. If continuity exists, the armature coil is grounded and the complete starter motor unit must be replaced.
3. Check for continuity between all of the commutator segments. Continuity must exist in each case.
4. Check continuity between the brush that is wired to the stator coil and the starter motor cable. Lack of continuity indicates an open circuit in the stator coil, and the starter motor unit should be replaced. Resistance should not exceed 0.05 ohms.

Checking resistance between the commutator and armature core



Checking resistance between the commutator segments



Checking resistance between the brush and starter motor cable

5. Examine the carbon brushes for damage to the contact surfaces and measure their length. Replace the brushes as a set if either one measures less than 4.5 mm (0.18 in.), or if they are damaged in any way.
6. Brush spring tension should be measured with a small pull-scale. Replace the springs if they have weakened to less than 550 g tension.
7. The mica underent of the commutator should be maintained at 0.7 mm (0.027 in.). Any carbon deposits should be cleaned out of the commutator grooves, and a piece of hacksaw blade or the like used to increase the undercut depth if necessary.
8. Polish the commutator with fine emery cloth and then clean it thoroughly before installing.
9. Measure the diameter of the commutator. The armature should be replaced if the measurement is less than 27 mm (1.06 in.)
10. Check the condition of the armature bearings and replace them as a set if any damage is noted.
11. Check the condition of the oil seal and replace it if the seal lips are cracked or worn.
12. Unsealed bearings should be lubricated with 20W or 30W motor oil before assembly. Coat the lips of the oil seal with white grease before assembly.

Starter Solenoid

1. If the battery is in reasonably good condition, and nothing at all happens when the starter button is pushed, check the solenoid.
2. Disconnect the starter cable at the solenoid. When the button is pushed, there should be an audible "click" which indicates that the solenoid is opening.
3. If further testing is necessary, remove the solenoid from the machine.

CAUTION: *Be sure to disconnect the cables at the battery before disconnecting the solenoid terminals.*

Connect a fully charged 12-volt battery across the solenoid low-tension leads and check for continuity across the high-tension terminals with an ohmmeter or self-contained test light. If there is no continuity, replace or repair the solenoid.

4. Check for continuity across the low-tension terminals with an ohmmeter or self-powered test light. Resistance should be 3.5 ohms. If there is no continuity, the primary winding of the solenoid is broken, and the unit must be replaced.
5. If starter trouble began just after the starter button housing was disassembled or moved for any reason, check the connections at the switch as they may have come adrift.

ELECTRICAL COMPONENTS

Horn

1. If the horn fails to sound, check that there is 12 v on the brown horn lead. If there isn't, check for a broken wire.
2. If the brown lead checks out, check that the pink wire is grounded when the horn button is pressed. If it isn't, check the horn button.
3. If the wiring is satisfactory, replace the horn.

Brake Light

1. If only one of the two brakes fails to activate the brake light, the problem is probably confined to that switch.
2. If neither switch will activate the brake light, first check the brake light bulb. If it is in workable condition, check that there is 12 v on the yellow brake light lead.
3. If there is voltage on the yellow lead, check for voltage on each brown lead at the brake light switches.

Taillight

1. If the taillight will not work, check the bulb first.
2. If it is satisfactory, check for voltage on the blue lead. If there is voltage on this wire, check for a good ground (black wire).

Turn Signals

1. If only one side fails to work, check both bulbs on that side first.
2. If the bulbs are operable, check for voltage on the green (right) or brown (left) leads. If there is voltage here, check the grounds (black leads).
3. If neither side will work, check for voltage on the brown/white lead at the handlebar turn signal switch. Then check for voltage on the brown lead at the turn signal flasher relay.
4. If these checks are satisfactory, replace the flasher relay. If the turn signals still will not operate, replace the flasher switch. If this will not work, the entire self-cancelling system must be checked out (see below).

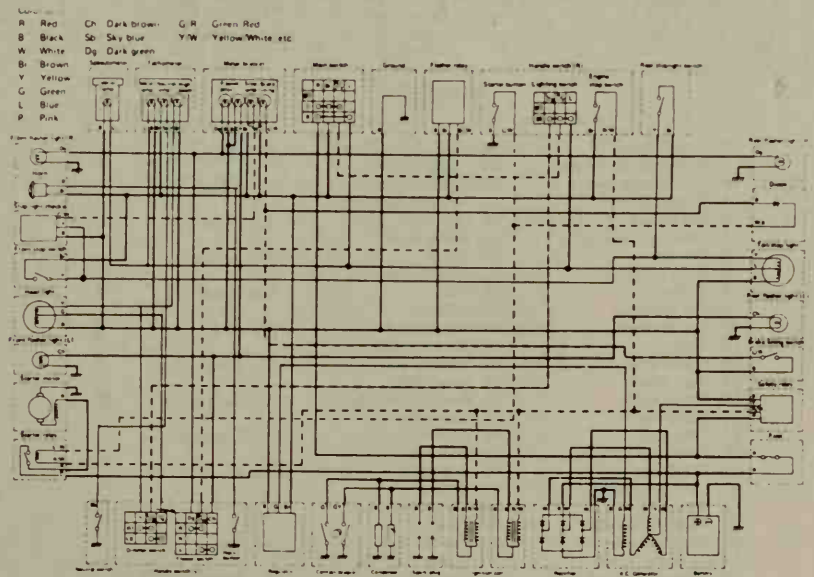
Neutral Indicator

1. If indicator light fails to come on, check the bulb first.
2. If the bulb is satisfactory, check that there is voltage on the blue wire at the switch. If there is, replace the switch itself.

Self-Cancelling Turn Signal System

1. In the event that the self-cancelling system fails to operate properly, first disconnect the 6-prong connector from the flasher cancelling unit and try the turn signals. If both sides operate normally, the trouble can be confined to the cancelling unit itself, the handlebar switch reset circuit, or the speedometer sensor circuit.
2. Connect an ohmmeter set to the R x 100 range across the white/green and black wires on the wiring harness side of the 6-prong connector. Turn the speedometer shaft. The ohmmeter needle should swing back and forth between zero and infinity four times. If this happens, it indicates that the speedometer sensor circuit is functioning properly. If the meter does not function in this manner, either the sensor or the wiring harness is defective.
3. Check for continuity between the yellow/red lead of the 6-prong connector on the wiring harness side and ground on the chassis. When the turn signal switch is *off*, there should be infinite resistance. When the switch is pushed to either "L" or "R", there should be no resistance. If this is not the case, check the wiring harness and the handlebar switch circuit.
4. If no defective operation is apparent in the above tests, replace the self-cancelling unit.
5. If the turn signals operate only when the turn signal button is pushed to "L" or "R" and they shut off immediately when the button is released, replace the self-cancelling unit.

Note the following concerning the self-cancelling turn signal system:



a. Yamaha recommends that the turn signals be shut off manually after a turn is completed.

b. If the self-cancelling unit fails, the turn signals can be used manually by simply disconnecting the 6-prong connector from the unit.

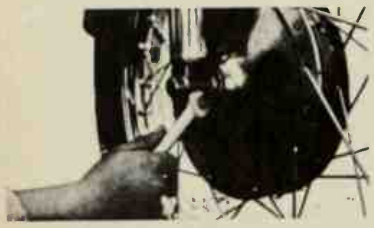
CHASSIS

WHEELS

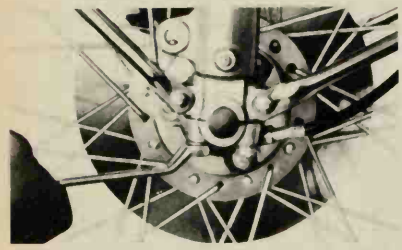
Front

REMOVAL AND INSTALLATION



1. Support the front wheel off the ground by placing a jack or similar support beneath the engine.

CAUTION: *Be sure that the motorcycle is firmly supported.*

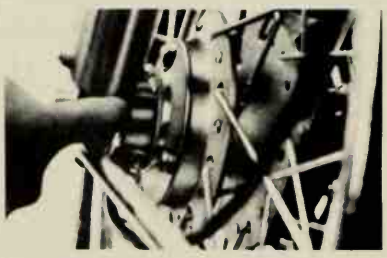


2. Remove the axle nut.

3. Disconnect the speedometer cable at the hub. On drum brake models, disconnect the brake cable.

4. Loosen the axle cap nuts on forks so equipped, or the axle pinch-bolt on the right fork slider on earlier model forks. Pull out the axle and remove the wheel.

Loosening the pinch bolt



Loosening the axle cap nuts

5. On disc brake models, place a small sheet of cardboard between the brake pads to prevent residual line pressure from forcing them together.

NOTE: *Do not apply the brake while the wheel is removed.*

6. Installation is the reverse of removal. When installing the wheel on drum-brake models, be sure that the brake plate is engaged with the brake anchor on the slider. Position the speedometer drive box so that the cable has no sharp bends.

Tighten the axle nut to 50–72 ft lbs. Tighten the axle cap nuts (if fitted) to 15 ft lbs. Be sure to tighten the forwardmost nut first.

Fit the speedometer drive so that the cable is not sharply bent

Rear

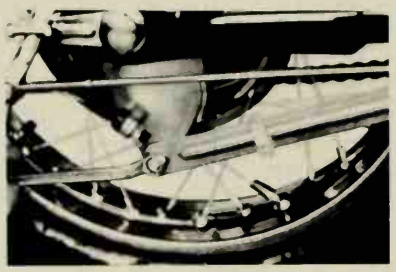
REMOVAL AND INSTALLATION

Rear Drum Brake

1. Disconnect the rear drive chain.

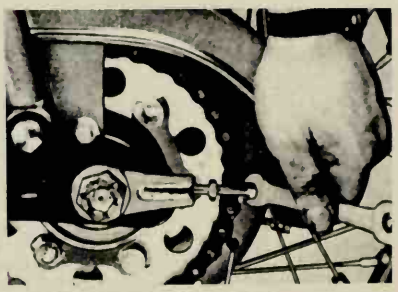
2. Pull out the clip which secures the brake anchor to the brake plate, remove the nut and washers, and detach the anchor from the plate.

3. Disconnect the rear brake rod from the lever on the brake plate by removing the brake adjuster nut and depressing the pedal.



4. Remove the axle nut cotter pin (use a new one when installing the wheel), and remove the axle nut.

5. Loosen the chain adjuster bolt locknuts, back off the adjuster bolts, and bend them down and out of the way.



6. Pull out the axle. Remove the spacer on the right side. Remove the right-side chain adjuster plate.

7. Take out the brake plate, and have an assistant lean the machine to the left while pulling the rear wheel assembly back and out of the frame.

8. Installation is the reverse of removal. Tighten the rear axle nut to 87–130 ft lbs.

Rear Disc Brake

1. A special tool is needed to remove the rear wheel. This tool, a length of wire with hooks to support the rear wheel, is supplied in the tool kit.

2. With the machine on the side stand, attach one end of the tool to the frame hook. Compress the shocks as much as possible and hook the other end of the tool to the swing arm. Place the machine on the center stand.

3. Disconnect the drive chain.

4. Remove the axle nut cotter pin and unscrew and remove the axle nut.

5. Hold the brake caliper in position so it will not fall out of place, and pull out the axle. Remove the rear wheel assembly.

NOTE: *Do not apply the brake while the wheel is off the machine.*

6. Installation is the reverse of removal. Before fitting the wheel, check that there is sufficient clearance between the brake pads to install the disc. Grease the lips of the wheel bearing grease seals. Tighten the axle nut to 87–130 ft lbs.

Wheel Bearings

REMOVAL

1. After removing the wheel, remove the brake plate on drum brake models, or the brake disc on disc brake machines.

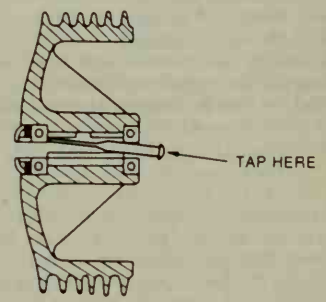
2. Remove the speedometer drive box on disc brake machines.

3. Remove any wheel bearing covers or retainers fitted to either side of the hub.

4. Pry out the grease seals. Once removed, the seals should be replaced with new ones.

5. Reach through the hub with a suitable punch, move the wheel bearing spacer as far as possible to one side to achieve a purchase on the wheel bearing, and drive it out. Remove the spacer. Drive out the remaining wheel bearing from the other side of the hub.

INSPECTION



1. Wash the wheel bearings thoroughly in a solvent to remove all of the old grease.

2. Inspect the general condition of the bearings. There should be no rust, pitting, or obvious signs of wear or damage on either balls or races.

3. Slowly rotate the bearings. Rotation should be smooth, noiseless, and free of binding or unevenness. If any of the above conditions exist, both bearings should be replaced.

4. Place each bearing on a flat surface and hold the inner race firmly in place. Attempt to move the outer race up and down. If any play is evident, the bearings should be replaced.

5. If equipment is available, a dial gauge can be used to check bearing run-out. Pass the axle through each bearing in turn and check the axial and diametrical run-out with the gauge. If axial run-out exceeds 0.1 mm (0.004 in.) or if diametrical run-out is greater than 0.05 mm (0.002 in.), the bearings should be replaced.

Removing a wheel bearing

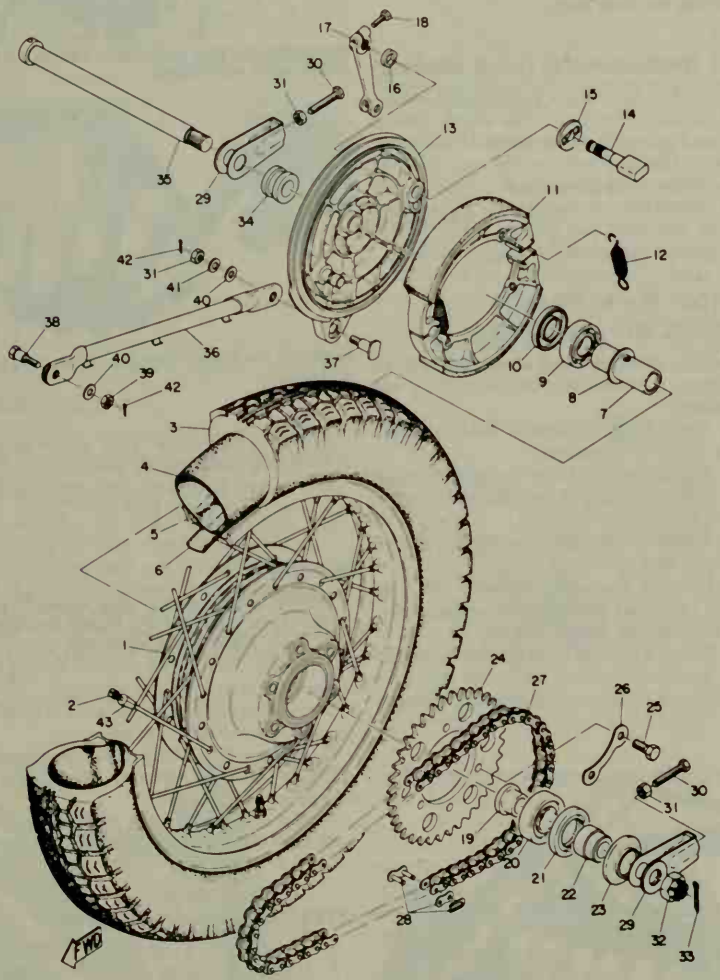
DISC BRAKE SERVICE

To check diametrical run-out, the dial indicator is placed directly on top of the outer race and the race moved up and down.

To check axial run-out, the gauge is positioned to bear against the side of the outer race and the race moved back and forth while holding the inner race in place.

INSTALLATION

Assembly is the reverse of the above.



Note the following points:

a. Pack the bearings with a good grade of wheel bearing grease. Put a small handful of the grease in the hub as well.

b. Do not forget to install the spacer in the hub before installing the bearing.

c. Bearings may be driven into place using a suitably sized socket or a bearing driver. If one side of the bearing is sealed, install it with the sealed side facing outward.

d. Use new grease seals and lubricate them with oil to make installation easier.

Flushing

The brake system should be flushed out every 12,000 miles, or every 2 years.

1. Attach a length of vinyl tube to the bleed valve on the brake caliper and put the other end into a small container.

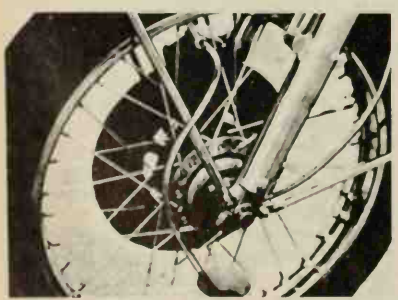
2. Remove the master cylinder cap, and the diaphragm. Loosen the bleed valve about ½ turn. Pull the brake lever slowly to the handgrip, then tighten the bleed valve. Release the lever. Repeat until the master cylinder is almost empty.

3. Add new brake fluid to the master cylinder and continue squeezing and releasing the brake lever slowly until the new fluid begins to come out of the vinyl tube. Bleed the system as outlined below.

Bleeding

The brake hydraulic system must be bled whenever any part of the system has been disconnected or removed for service. When refilling the master cylinder reservoir, use only brake fluid conforming to DOT 3 specifications. Any brand meeting this requirement is acceptable. The brake fluid container of all reputable brands will be plainly marked with the standards the fluid meets or exceeds.

NOTE: *It is sometimes helpful to let the cycle sit for several hours before bleeding the system. Pulling and tapping on the lines will help expel any air bubbles trapped in the system. If you find that you can't get the system bled properly and the master cylinder has been dry for awhile, the seals inside the cylinder may have become dried and cracked. In this case rebuild the master cylinder.*



1. Top up the reservoir with brake fluid and replace the cap to keep dirt and moisture out and the fluid in. Cover the gas tank with a thick cloth to avoid damage due to spilled brake fluid.
2. Attach one end of a small diameter rubber hose to the bleed valve on the caliper, and place the other end in a jar which contains several inches of clean, new brake fluid. Be sure that the end of the hose is submerged in this fluid. Arrange the hose so that it loops upward after leaving the bleed valve, and see that it has no kinks or sharp bends.
3. Pump the brake lever rapidly several times until some resistance is felt and, holding the lever against the resistance, open the bleed valve about one-half turn. When the lever bottoms, close the valve (do not overtighten) and then release the lever.
4. Repeat the operation until no more air is released out of the hose and the brake lever is firm in operation. Check the fluid level in the reservoir often to make sure that it doesn't go dry and draw more air into the system. Do not reuse fluid that has been pumped out of the system. Do not use fluid that has been stored for more than a few weeks after the seal on its container has been opened, as brake fluid will absorb moisture from the air and may corrode the master cylinder and caliper.
5. Refill the reservoir to the level mark when through (but do not overfill). Avoid overtightening the cap or fluid will weep around the cap edge.

FRONT DISC BRAKE

Pad Replacement (Early Models)

Brake pads are easily removed and replaced after removing the front wheel and prying the pads carefully out of the caliper with a screwdriver.

Note that fitting new pads in place of a pair which were considerably worn will result in a rise in the reservoir fluid level. Excess fluid may be drained off by temporarily loosening the bleed screw on the caliper.

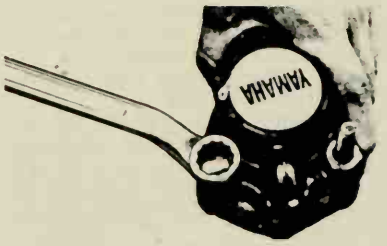
Bleeding the brake

Removing the brake pads

Pad Replacement (Late Models)

1. Unbolt the caliper from the fork slider.
2. Remove the pad screw which secures the fixed pad on the wheel side of the caliper. Remove the fixed pad.
3. Remove the piston pad.
4. Installation is the reverse of removal. Secure the fixed pad phillips screw with a non-permanent thread-locking compound.

Caliper (Early Models)



REMOVAL AND DISASSEMBLY

NOTE: *A compressed air supply will be necessary to remove the pistons from the caliper.*

1. Use a length of tape to hold the brake lever in the ON position.
2. Disconnect the brake line from the caliper. Cover the end of the line with a small plastic bag.
3. Unbolt the caliper from the fork slider, lift it up, and remove it.
4. Remove the pads. Remove the two bridge bolts and the hex-head caliper bolts, and separate the caliper halves.
5. Remove the seal from the fluid passage.
6. Apply compressed air to the fluid passage in each caliper half to force out the pistons.

Fixed pad securing screws

Removing the caliper bolts

Removing the fluid seal. This seal must be replaced when assembling

Removing the pistons from the caliper with compressed air

NOTE: *This is the only recommended method of removing the pistons.*

7. Remove the piston seal and the dust seal from each caliper half.

INSPECTION

NOTE: *Caliper components should be kept free of any solvent. Parts should be cleaned in fresh, clean brake fluid only.*

1. Check the pads for wear or scoring and replace them as a set if necessary.
2. Inspect the pistons for scoring or other signs of wear. Replace as necessary.
3. Replace any damaged seal in the unit. All seals should be replaced every two years regardless of appearance.
4. The two bridge bolts must be replaced each time that they are removed.

ASSEMBLY AND INSTALLATION

1. Clean all parts in new brake fluid.
2. Install the dust seal and piston seal in the caliper halves.
3. Coat the caliper cylinder walls and the pistons with new brake fluid, and then carefully insert each piston into its own caliper half.

Be sure that the piston goes in smoothly.

4. Install the caliper seals.
5. Fit the two caliper halves together, and replace the two hex-head bolts and tighten them to 16–23 ft lbs.
6. Install new bridge bolts and tighten them to 56–71 ft lbs.
7. Install the pads. It will be necessary to

push the pistons back by hand when installing the pads.

8. Replace the caliper on the fork slider, tightening the bolts to 30–37.2 ft lbs.

9. Refit the brake line to the caliper and tighten it to 10–13.4 ft lbs.

Brake Disc (Early Models)

1. Check the disc for run-out by securing a dial gauge to the fork slider. If run-out is 0.15 mm (0.006 in.) or more, remove the disc and inspect it closely. If the disc is not warped, suspect the wheel bearings.

2. Check the thickness of the disc with a micrometer. Minimum allowable thickness is 6.5 mm (0.26 in.). Replace the disc if it measures less than this amount.

3. Check the disc for scoring or grooves and replace it if the surface is not reasonably smooth. In the event that the disc is scored badly enough to need replacement, be sure to fit new brake pads as well.

4. Clean the disc surfaces as thoroughly as possible, removing any dirt or grease. Use a quickly evaporating disc cleaning agent, several brands of which are readily available in spray cans.

Caliper (Late Models)

REMOVAL

1. Disconnect the brake line from the caliper. Plug the end of the brake line to prevent loss of brake fluid.

2. Remove the mounting bolts and take the caliper from the fork slider.

DISASSEMBLY

1. Remove the phillips screw which secures the fixed pad and take out the pad and pad spring.

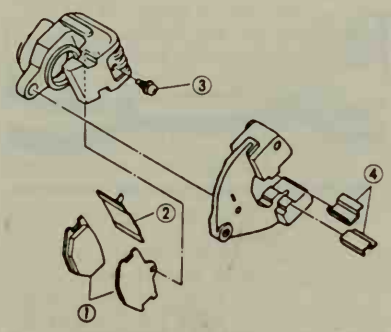
2. Remove the piston pad.

3. Remove the caliper support bolt. Separate the caliper and support bracket. Remove the piston dust seal and retaining ring.

4. Apply compressed air to the brake line fitting on the caliper and force out the piston.

CAUTION: *Be sure your fingers are clear of the piston, as it may come out with some force.*

5. Remove the piston seal.

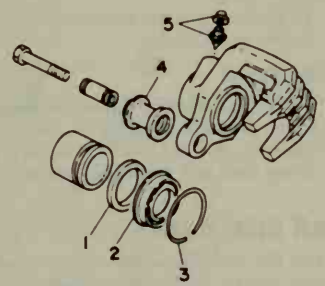


Caliper mounting bolts

INSPECTION

1. Clean all parts in new brake fluid. Do not use gasoline or other solvents.

2. All rubber parts should be replaced with new ones once the caliper has been disassembled. These parts should also be replaced every two years as a matter of preventive maintenance.



Caliper pad components: 1, pads; 2, pad spring; 3, screw; 4, retainers

3. Check the piston for scoring or other obvious signs of wear, and replace it if damage is noted. Check the caliper bore as well.

ASSEMBLY

1. Using a new caliper support bolt is recommended. As noted above, all rubber parts must be replaced as well.

2. Lightly lubricate the piston seal with fresh brake fluid and install it in the caliper. Be sure that the seal is properly seated.

Caliper components: 1, piston seal; 2, boot; 3, dust cover clip; 4, bushing boot; 5, bleed screw

3. Lubricate the sides of the piston with brake fluid and install it.

4. Fit the caliper and support bracket together, not forgetting the bushing and bushing boot. Install the support bolt and tighten it to 11–15 ft lbs.

5. Install the brake pads. Secure the fixed pad phillips screw with a non-permanent thread-locking compound. Grease the pad-shim contact area before installation. Bend each tab of the shim over the piston pad

INSTALLATION

1. Tighten the caliper mounting bolts to 21–29 ft lbs.

2. Tighten the brake line banjo bolt to 18–25 ft lbs. Bleed the system.

Brake Disc (Late Models)

The brake disc normally requires no service of any kind. However, if the disc becomes scored for any reason, it should be replaced and a new set of pads should be installed. A badly scored disc will reduce the effectiveness of the brake and shorten pad life considerably. If the front brake lever oscillates or fluctuates when the brake is applied at speed, the indication is that the brake disc is warped or bent. Check the run-out of the disc with a dial indicator and replace it if run-out exceeds 0.15 mm (0.006 in.). Measure disc thickness. If it is less than 4.5 mm (0.18 in.), it should be replaced. To replace the disc:

1. Remove the wheel.

2. Bend back the locktabs, unscrew the bolts, and remove the disc from the hub.

3. Mount the new disc on the hub and tighten the bolts evenly, using new locktabs or thread-locking compound to secure them. Proper torque is 12–16 ft lbs.

4. Examine the brake pads and replace them if they are close to the limit of wear or have worn in an unusual pattern.

Master Cylinder (All Models)

REMOVAL

1. Disconnect the front brake light switch leads.

2. Remove the brake lever. Note the return spring.

3. Disconnect the brake line from the

Removing the brake lever and spring

master cylinder. Take adequate precautions to avoid spillage.

4. Remove the two master cylinder handlebar clamp bolts and remove the master cylinder assembly.

DISASSEMBLY

1. Remove the master cylinder cap and diaphragm and drain off and discard the brake fluid.

2. Remove the master cylinder rubber boot.

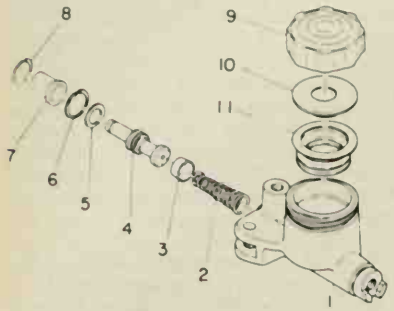
3. Remove the snap-ring. Take out the piston assembly. The spring will remain in the master cylinder.

4. Remove the spring and stopper valve.

5. Remove the stopper plate and the cylinder cups.

INSPECTION

1. Wash all parts in new brake fluid only.



2. Check the master cylinder port for clogging due to foreign matter.

3. Be sure that the reservoir is clean.

4. Check the walls of the master cylinder for grooves or score marks.

5. Check the outlet end for dents or other damage.

In the event of any permanent damage, replace the master cylinder body.

Master cylinder components

Removing the snap-ring

Removing the piston assembly

6. Check the piston for wear or rust, and replace as necessary.

7. Check the condition of the cylinder cup noting any evidence of grooved wear on the contact surface. Replace if any is evident.

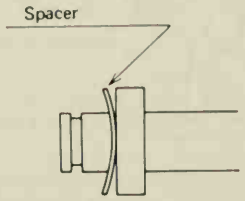
8. Check all rubber parts for wear, damage, or swelling and replace them as necessary. Note that all rubber parts should be replaced every two years regardless of appearance.

9. Check the reservoir diaphragm for cracks or damage to the edges and the accordion pleats. Check the diaphragm and the boot for swelling.

These components should be replaced if damaged or worn, and replaced every two years regardless of appearance.

10. The master cylinder spring minimum length is 60.4 mm. Replace it if it is shorter than this or if it shows signs of damage.

11. Check the brake hose and line for cracks or seepage. The brake hose should be replaced every 4 years regardless of condition.



12. When installing the hose and line, note that they should not contact the forks or frame at any point except where attachment clips are fitted.

ASSEMBLY

1. Soak the cups in new brake fluid for a time before assembly.

Using the special tool to install the cylinder cup

Be sure that the spacer is properly installed

2. Use the special cylinder cup installer when fitting the cup to the piston.

3. Install the stopper plate into the master cylinder. Insert the spring and valve.

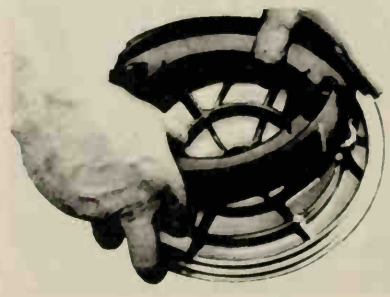
4. Insert the piston into the master cylinder. Take care not to scratch the piston or cylinder wall. Fit the snap-ring. Be sure that it is firmly seated.

5. Fit the boot into the grooves of the master cylinder and piston.

INSTALLATION

Bolt the master cylinder to the handlebar. Connect the brake and tighten the banjo bolt to 17–20 ft lbs. Fill the master cylinder with fresh brake fluid and bleed the system.

REAR DISC BRAKE



The rear disc brake components are virtually identical to those for the late model front system except for the method of mounting.

To remove the rear caliper, disconnect the brake line from the caliper, unbolt the brake anchor, and remove the rear axle.

For all service procedures, refer to the "Front Disc Brake" section above.

DRUM BRAKES

1. All rear drum brakes are single-leading shoe units, while the drum fitted to the front of early 650 cc models is a twin-leading shoe unit.

Removing the brake shoes from the plate

2. Brake shoes should be inspected for wear. Lining thickness, when new, is 4 mm (0.16 in.), and brakes should be replaced if lining is less than 2 mm (0.08 in.) thick.

3. Brake shoes should also be checked for scoring or for an oil-soaked condition. If scored, the linings should be replaced and the drum checked for scoring as well. If oil soaked, replace.

4. Even minor imperfections of the brake drum should be removed by having the drum turned on a lathe.

5. Linings should be sandpapered to remove any glaze or dirt, then cleaned thoroughly prior to installation.

6. The brake shoes can be removed from the backing plate by pulling them up and off, after disengaging them from the anchor pin. Check the brake springs for distortion, corrosion, or other damage.

7. After removing the brake shoes, the brake cam (or cams on twin-leading shoe brakes) should be tapped out of the backing plate. Remove any old grease from the cams and then take off any rust or corrosion with medium grade sandpaper. Clean the cams thoroughly in a solvent; lubricate with chassis grease before installing in the backing plate. Check the condition of the cam seal and replace if necessary.

8. An off-on-off feeling while applying the brake may be due to a warped drum. Most often it is possible to correct this condition by having the drum turned down on a lathe. Most machine shops have the facilities to accomplish this task.

FRONT FORKS

XS1, XS1B

Two different styles of forks are fitted. Early model forks have an external fork spring covered by a rubber boot.

Later model forks have an internal spring, chrome fork tubes, and a dust cover over the top of the fork slider.

In the following procedures, make allowances for the differences in each type.

REMOVAL AND DISASSEMBLY

1. Remove the front wheel and fender. On disc brake models, remove the caliper from the fork slider.

2. Lift up the dust cover from the top of the slider, or move the boot out of the way, and use a strap wrench to unscrew the outer nut from the slider. Use the axle, inserted through the sliders, to keep them from turning while the nut is unscrewed.

The chrome may be protected with a piece of rubber before fitting the strap wrench.

If a strap wrench is not available, it may be possible to remove the outer nut by tightening a large heater hose clamp on it (with a piece of rubber beneath it to protect the chrome). A vise-grips or large pliers can then be used on the clamp worm screw to turn the nut. The slider must be held in place while removing the nut.

3. Pull the slider down and free of the fork tube. Drain out the fork oil.

4. Take out the springs, if they are the internal type.

5. To remove the fork tube, remove the handlebars, the fork crown bolts, and loosen the lower triple clamp pinch-bolt. Pull the tube down and free of the triple clamps.

6. Remove the external fork spring and boot, if fitted. Remove the dust cover and dust seal, if fitted.

7. Remove the outer nut, O-ring, sliding bushing, spacer, and spring seat.

INSPECTION

1. The fork oil seals are pressed into the top of the outer nuts. Seals should be replaced every time the fork is disassembled.

NOTE: *Grease the lips of new seals before installation.*

2. Check the straightness of the fork tubes. Slightly bent tubes may be straightened with a press, but if the tubes are kinked or the metal buckled, replacement is the only solution.

3. Check the oil seal contact area on the outside of each tube and make sure that it is free of dents, scoring, rust or other surface irregularities which would make oil sealing impossible.

4. Check the fit of the sliding bushing on the fork tube. When new, the bushing should have a clearance of 0.2 mm (0.008 in.). If clearance exceeds 0.5 mm (0.020 in.), replace the sliding bush.

5. Note any scoring on the inner surface of the sliding bushing, or score marks on the surface of the fork tube where the bushing contacts it.

6. Check the condition of each fork spring, noting any collapsed coils, fatigue cracks, or other damage, and replace them as necessary. Springs for each leg should be of equal length.

7. Check the condition of the slider and fork crown bolt O-rings, and replace them if necessary.

ASSEMBLY AND INSTALLATION

1. Wash all metal parts thoroughly in solvent.

2. Refit the sliding bushing, O-ring, outer nut with oil seal installed, and dust seal and cover, or external fork spring and rubber boot depending on fork type, over the top of the fork tube.

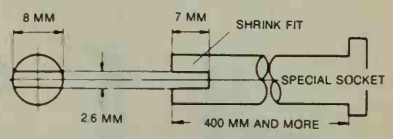
3. Slide the fork tube through the triple clamps, replace the internal spring, spring seat, and spacer; refit the fork cap bolt and tighten it.

4. Tighten the lower triple clamp pinch-bolt.

NOTE: *The fork cap bolts must be tightened* BEFORE *the lower triple clamp bolts.*

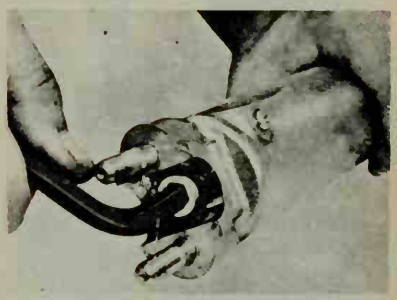
5. Replace the slider, then screw the outer nut into the slider and tighten it.

6. Refit the fender, disc brake caliper, and wheel.



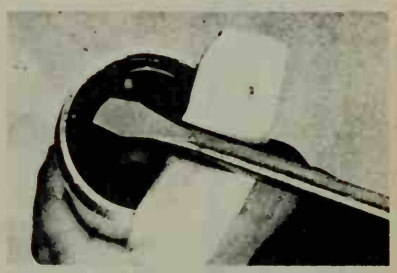
All Other Models

REMOVAL AND DISASSEMBLY



1. Remove the front wheel and fender. Remove the caliper from the right fork slider. Remove the fork cap bolts.

2. Loosen the upper and lower triple clamp pinch-bolts for one of the fork legs, then pull down on the fork leg and remove it from the machine. Drain the oil out of the top of the fork tube. Remove the other fork leg in the same way.



3. Remove the dust cover from the top of the fork slider. Remove the allen bolt at the bottom of the slider by pulling the slider to the end of its travel and then loosening the allen bolt. If this fails, a special socket must be made as shown.

Special tool for removing the slider allen bolt

Removing the slider allen bolt

Removing the slider oil seal

4. Separate the fork slider from the tube assembly. Take out the damper.

5. Remove the slider oil seal circlip, the washer, and then pry out the seal. New seals must always be used upon reassembly.

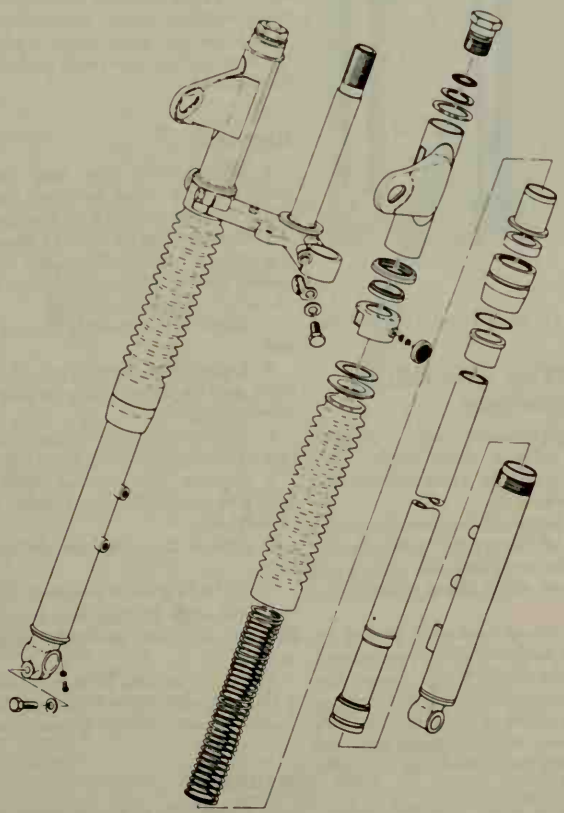
INSPECTION

1. Check that the fork tubes are perfectly true. If bent, they may be straightened with a press. If the tubes are kinked, or the metal creased, the tube must be replaced.

Check the outer surface of the fork tubes along the oil seal contact area. Any rust, nicks or grooves on the tube must be removed or the seals will leak.

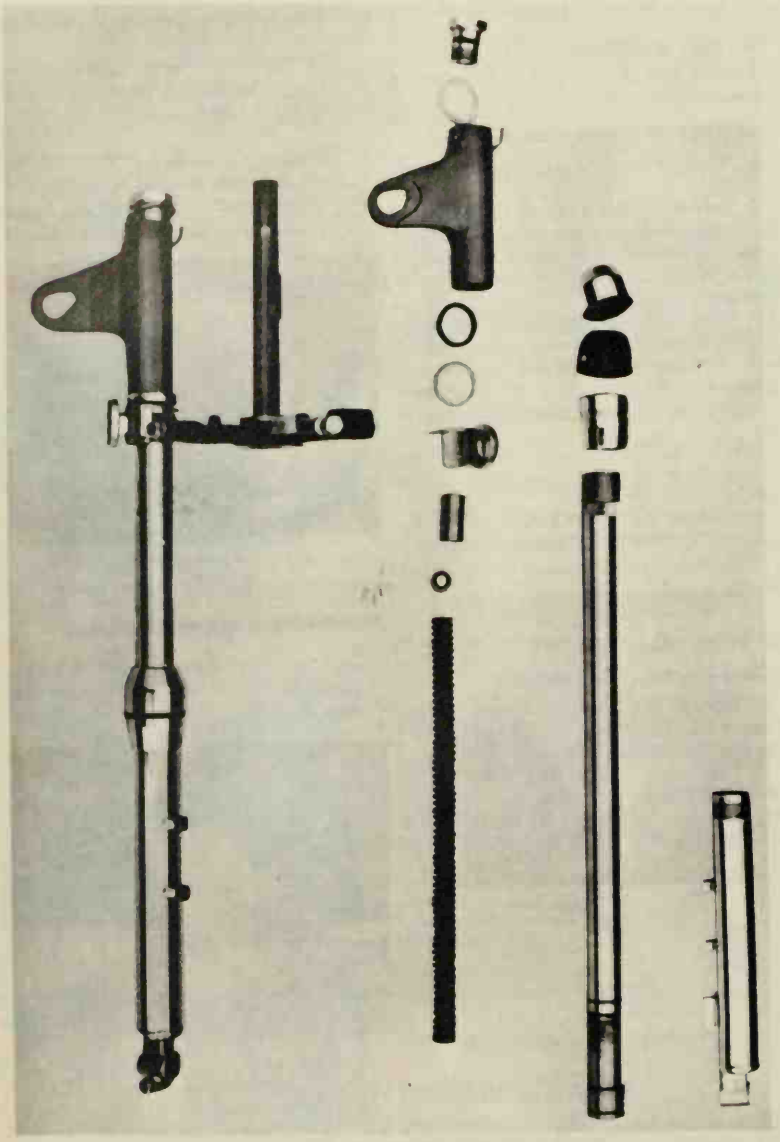
2. Check the fork spring for general condition, noting any closed coils or fatigue wear. Both fork springs must be of equal length.

3. Check the damper piston for wear or damage.



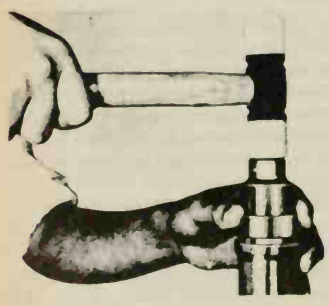
ASSEMBLY AND INSTALLATION

1. Clean all parts thoroughly.



2. New fork seals must be used.

3. Drive in the new seal with a suitably sized socket or drift, refit the circlip, and install the slider onto the tube assembly. Replace and tighten the allen bolt in the fork slider bottom.



NOTE: *Lubricating the seal lips will aid in installation.*

Later XS1B fork assembly

Installing a slider oil seal

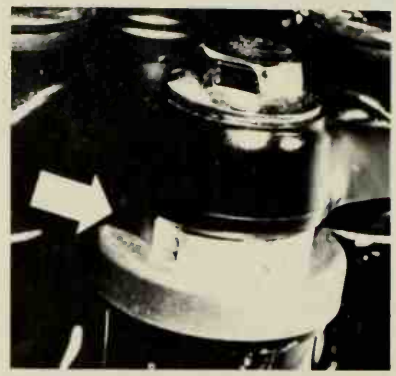
4. Put the dust cover into position over the top of the slider.

5. Install the assembled fork leg up through the triple clamps. Tighten the pinch-bolts to 5.8–9 ft lbs.

6. Add the correct amount and grade of fork oil (see the "Maintenance Data" chart at the end of Chapter 2), and install the fork cap bolts.

STEERING STEM ASSEMBLY

Bearing Adjustment



1. The steering stem bearings are uncaged 3/16 in. (upper) or ¼ in. (lower) balls. They are adjusted by means of a ring nut beneath the upper triple clamp.

2. To check bearing adjustment, support the front wheel off the ground. Grasp the tip of the front fender and place your other hand beneath the lower triple clamp at the frame lug.

3. Attempt to move the fork by pulling up on the tip of the fender. If play or movement can be felt at the lower triple clamp, the bearings are adjusted too loosely or are worn. An alternate method is to grasp the fork sliders and attempt to move them back and forth in line with the motorcycle. No play should be noted.

4. Turn the forks slowly from lock-to-lock. Movement should be smooth, silent, and effortless. If any binding or uneven movement is felt, the balls and races are either too tightly adjusted or they are worn. If the steering feels uniformly stiff, the bearings are too tightly adjusted. If any noise is noted, the bearings are damaged or some are missing.

5. With the front wheel off the ground, release the front forks from a few degrees off the centered position. The fork should fall

Steering head bearing adjuster nut

freely to either side of their own weight. If they will not, the bearings are too tightly adjusted, the steering stem is bent, the races are extremely worn, or some of the bearings are missing.

6. To adjust the bearings, remove the gas tank. The bearings are adjusted by means of the adjuster nut under the upper triple clamp.

7. Tighten or loosen the adjuster nut a little at a time until the steering stem adjustment conforms to that outlined above.

8. If proper adjustment is not possible, the bearings and races will probably need to be replaced.

Removal

1. The steering stem may be removed with the forks intact provided that the machine is supported well off the ground.

2. Remove the handlebars after removing the nuts (1) beneath the upper triple clamp which secure the assembly in its rubber mounts (2). (See illustration)

3. Remove the steering damper knob and rod.

4. Loosen the lower triple clamp pinch-bolts, and the upper triple clamp pinch-bolts where fitted.

5. Loosen the upper triple clamp pinch-bolt behind the steering stem nut.

6. Remove the steering stem bolt and both fork top bolts, then remove the upper triple clamp.

7. Loosen the ring nut on the steering stem.

8. As the ring nut is loosened, the steering stem will begin to drop away from the frame. Remove the nut, and take away the assembly.

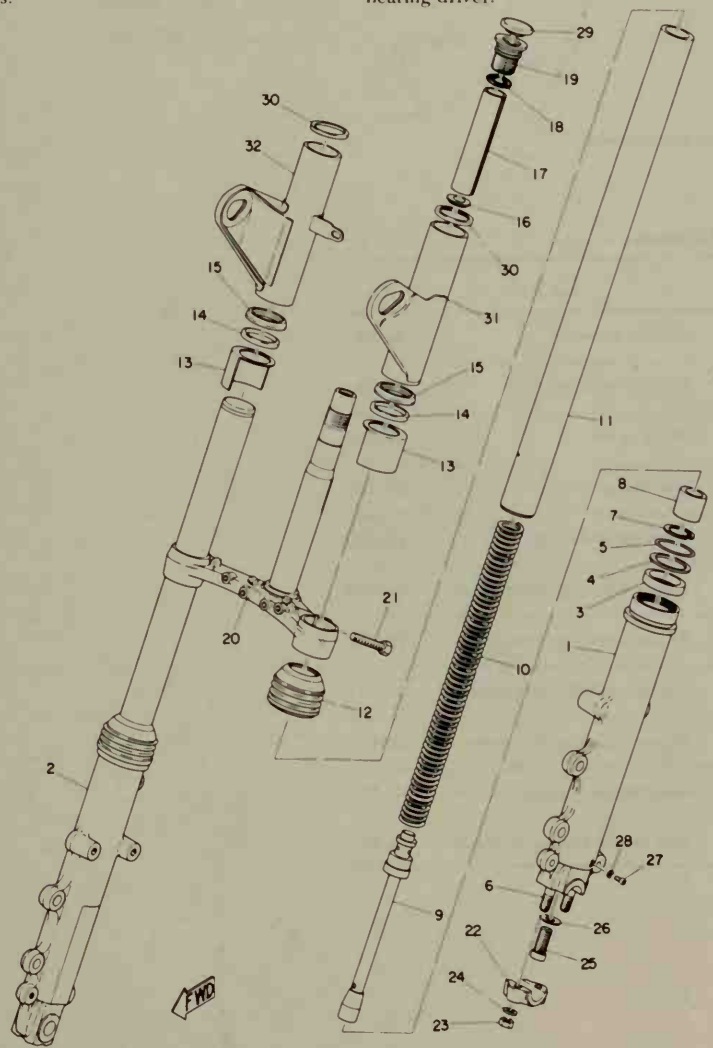
NOTE: *A special wrench is used on the ring nuts although a blunt punch and hammer can also be used if care is exercised.*

Inspection

1. Check all of the bearing balls after washing them thoroughly in solvent.

Lower bearing race

2. The balls should be replaced if rusted, pitted, dented, or scored.



3. Inspect the condition of the ball races checking for pitting, a rippled surface, or dents.

4. Replace all of the balls if any wear or damage is noted, and the races as well.

The bearing races in the frame lug are a press-fit and should not be removed unless replacement is necessary. If replacement is necessary, the old races can be removed by reaching through the frame lug with a suitable punch and tapping the race evenly around its circumference to remove it from the inside of the frame lug. Be sure that the race does not become cocked in its seat upon removal.

New races are installed with a suitably sized bearing driver, i.e., one which will drive the race squarely into its seat. Be certain that the race goes straight in.

These races can also be installed using a block of hard wood or a large socket of sufficient size to cover the race in place of a bearing driver.

Fork assembly for XS2 and following models

Assembly

1. Grease the lower race on the steering stem with a good grade of bearing grease, then arrange the balls on the lower race. There are 19 balls on the lower race.

2. Arrange the balls into the race on the frame. The upper race has 22 balls. Insert the steering stem, and replace the ring nut(s)

3. Continue to tighten the ring nut until all steering stem play has been eliminated but assure that the steering stem still pivots freely. With the front wheel off the ground, the forks should be able to swing to either side of their own weight.

Removing the frame races

Installing the frame races

REAR SHOCK ABSORBERS

1. The rear shock absorbers are sealed units. No service is possible. If the shocks leak oil, have a bent damper rod, damaged damper case, or other damage, they should be replaced.

Shock absorbers should be replaced in sets to ensure equal damping characteristics.

2. Shocks can be removed by removing the upper and lower mounts. To remove the spring, set the load adjuster on the softest setting, compress the spring, and remove the spring retainers.

3. With the spring removed, check the damping characteristics of the unit. The damper rod should be able to be pushed into the damper body with considerably less effort than it takes to pull it out. If little or no resistance is felt when pulling a damper rod out, the shock should be replaced. Shocks should have equal damping characteristics.

4. Tighten the mounting bolts to 17–26 ft lbs when installing the shock absorbers.

SWING ARM

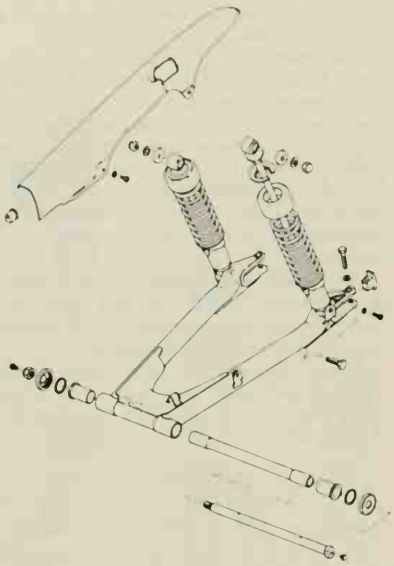
Inspection

1. Remove the mufflers.

2. Remove the rear wheel, shock absorbers, and chain guard.

3. Measure the distance between the top and bottom shock absorber mounts on both sides. The two measurements must be identical, or the swing arm will have to be replaced.

4. Check that the rear wheel mounting plates are parallel.



5. Grasp the legs of the swing arm and attempt to move it from side to side. Any noticeable side-play (more than 1 mm/0.04 in.) will indicate that the swing arm bushings need replacement.

The swing arm is most likely to be damaged if the machine is operated for any length of time with a broken or otherwise defective shock absorber.

Removal and Installation

1. Proceed as above. Then remove the swing arm pivot bolt nut and tap out the pivot with a long drift.

2. Remove the swing arm by pulling it straight back. Note the locations of any spacers or shims which may come off. They must be installed in their original locations.

Swing arm assembly

3. The swing arm should be inspected for cracks or fractures, especially around the welds.

4. Remove the bushings, tapping them out with a hammer and punch. Once the bushings are removed, they should be replaced.

5. Lubricate new bushings with a good chassis grease. Press the bushings into the swing arm.

6. Clean out the pivot bolt and ensure that all grease passages are clear. Install the swing arm on the machine. Grease and install the pivot bolt. After tightening the swing arm pivot bolt nut, move the swing arm up and down to ensure that movement is smooth and effortless.

7. Pivot bolt torque is 36–58 ft lbs.

Maintenance

NOTE: *Common maintenance procedures are explained in detail in "General Information."*

MT and MR Models

Lubrication

ENGINE

The crankshaft assembly (piston, con rod bearings, and left-side crankshaft bearing) is lubricated by the gas-oil fuel mixture. MT models have an oil pump driven off the kick-starter gear by way of the oil pump driveshaft. This system does not require maintenance except for a periodic check on the oil pump cable adjustment provided that the oil tank is kept full of oil. A level glass is provided in the oil tank for this purpose. The oil filter in the oil tank should be cleaned once a year or every 6,000 miles. The MR models use a premixed gas/oil fuel supply to lubricate the engine. Refer to the "Lubrication System" section for more information.

When adding oil to the oil tank on MT models, one of the following types of oil can be used:

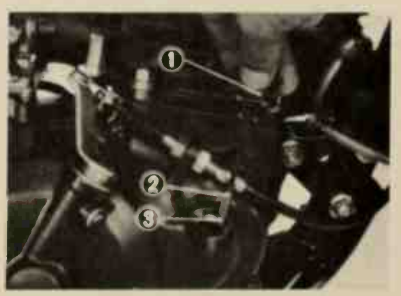
a. Any high-quality two-stroke oil labeled "BIA certified for service TC-W";

b. Any high-quality SAE 30W two-stroke oil designed for air or water-cooled engines;

c. A high-quality detergent-type motor oil, SAE 30W, rated "SE."

In extremely cold weather (average temperature below 15° F), use a high-quality detergent motor oil rated "SE," with a viscosity of SAE 10W–30.

TRANSMISSION



The transmission and clutch are lubricated by an oil bath. SAE 10W–30 or SAE 10W–40 service rating "SE" is recommended for all models.

Checking Oil

1. Start the engine and allow it to warm up for a few minutes.
2. Hold the motorcycle upright

Transmission oil level check bolt

Checking oil level with the dipstick (1). Nos. 2 and 3 indicate upper and lower level marks

3. Unscrew the dipstick (if fitted) and wipe it off. Reinsert, allowing the dipstick cap to rest on the top of the threads of its hole. The oil level should be between the maximum and minimum marks on the dipstick. If too low, add oil until the level is correct.

Changing Oil

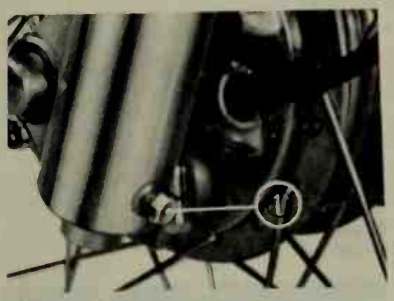
The transmission oil should be changed at least every 3,000 miles after break-in, or every 6 months.

1 Oil should be changed when the engine is at or close to operating temperature.

2. The machine should be held upright on a level surface.

3. Remove the filler cap.

4. Remove the drain plug and allow the oil to drain off for several moments.



5. Check the condition of the drain plug gasket. Replace it with a new one if damaged or cracked. Refit the drain plug and tighten firmly.

6. Fill the transmission with the correct type and quantity of oil. Capacities are given in the chart at the end of this section. After filling, allow a moment for the oil to distribute itself, then check the level with the dipstick or level plug.

FRONT FORKS

1. ATF is recommended for the front forks. If slightly stiffer damping characteristics are desired use SAE 30 oil.

2. Fork oil should be changed every 3,000 miles or once every 6 months.

Front fork drain plug location

3. To drain the fork oil, remove the drain plug at the lower portion of one of the fork sliders. Allow the oil to drain for several minutes into a suitable container, then pump the slider up and down several times. (Sit on the machine, apply the front brake, and push forward). After most of the oil is expelled, turn the forks all the way to the right to completely drain the right fork leg, or to the left for the left fork leg. Check the condition of the drain plug gasket. Replace it if necessary. Refit and tighten the drain plug.

4. Repeat the procedure with the other fork leg.

5. Support the front wheel off the ground and remove the fork filler cap from the top of each fork leg. On some models the cap is threaded into the top on the fork tube and can be removed with the proper wrench after the upper triple clamp pinch-bolts are loosened. On other models the upper spring plate is secured with a snap-ring located under a rubber

Fork filler caps

plug. To remove this type of arrangement, remove the rubber plug, compress the upper spring plate with a screwdriver and remove the snap-ring. Lift the wheel up until the upper spring plate can be removed. The handlebar clamps may have to be removed and the bars pulled back to allow access to the fork caps.

6. Add the correct quantity of ATF to each fork leg. Capacities for each model are given in the chart at the end of this section.

7. Inspect the condition of the fork filler cap O-ring if a threaded cap is fitted, and replace it if it is torn or cracked. Fit the caps and tighten them securely. If a snap-ring retainer is fitted, install the upper spring plate and compress it with a screwdriver. Install the snap-ring being sure that it is seated completely in the groove. Refit the rubber plugs. Tighten the handlebar holders and pinch-bolts if they were loosened. Allow a moment for the oil to settle in the forks before operation.

CHASSIS LUBRICATION

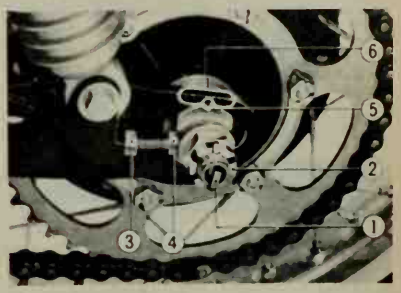
1. The swing arm pivot is fitted with a grease nipple. This item should be lubricated with a good grade of chassis grease every 3,000 miles. Grease should be applied until some of it shows at either end of the swing arm.

2. Wheel and steering head bearings are lubricated with bearing grease. This should be accomplished every 6,000 miles. Refer to "Chassis" for procedures.

Service Checks and Adjustments

DRIVE CHAIN

1. The chain should have about ¾ in. (20 mm) of total up-and-down free-play measured in the middle of the lower chain run.



2. *Before* checking or adjusting the chain slack, the following conditions should be met:

a. A support should be placed under the engine so that the rear wheel is off the ground, and the transmission placed in Neutral;

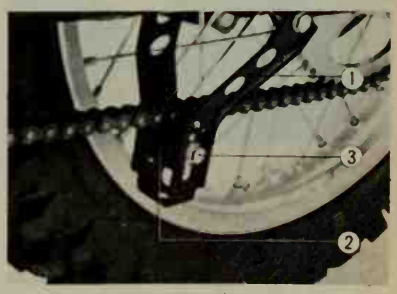
b. The chain should be clean and well lubricated;

c. The chain should have been checked for any tight spots by slowly rotating the wheel and checking for variances in the chain tension at different points. If a tight spot exists, the chain should be adjusted to the prescribed free-play at the tight spot. Note, however, that such a condition is indicative of a worn chain and probably sprockets which should be replaced as soon as possible.

3. Remove the axle nut cotter pin and loosen the axle nut several turns. Loosen the locknut on each adjuster bolt.

Drive chain adjustment

1. Axle nut cotter pin
2. Axle nut
3. Adjuster bolt locknut
4. Adjuster bolt
5. Index mark
6. Aligning marks



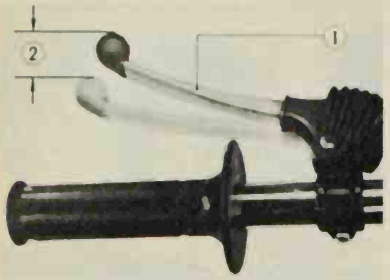
4. Turn each of the adjuster bolts in or out by equal amount until chain tension is approximately correct.

5. Check wheel alignment by means of the adjusting marks inscribed on both sides of the swing arm. Be sure that both adjusters are lined up with the same mark on each side. If not, turn one of the adjuster bolts in or out so that alignment is achieved.

6. Tighten the axle nut and check the chain tension. Correct if necessary. After adjustment is correct, torque the axle nut to 43–57 ft lbs. Fit a new cotter pin. Tighten the adjuster locknuts.

7. Check the condition of the drive chain protector. If the roller is excessively worn, replace it. If the protector has been bent, straighten it so that the chain runs through the center over the roller.

8. To adjust the roller on CR and MT models, loosen the lockbolt which runs through the center of the roller. Raise the roller until it just contacts the drive chain, (CR models) or has 10 mm (0.04 in.) of clearance (MT models), then tighten the lockbolt.

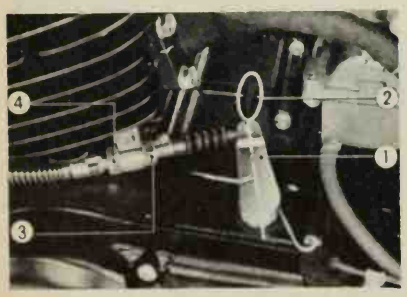


Drive chain protector (1), roller (2), and lockbolt (3)

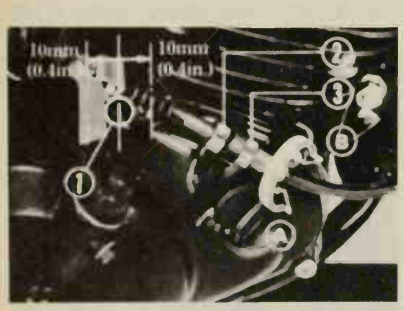
CLUTCH

Two adjustments are made to the clutch: cable adjustment and pushrod adjustment. Usually, the pushrod need not

be adjusted unless the clutch malfunctions. Cable adjustment must always be maintained at the proper specification.



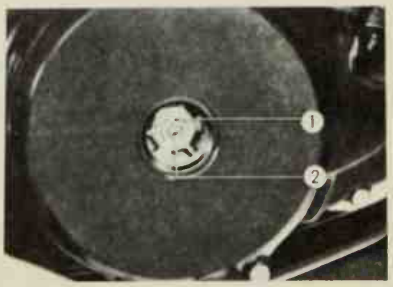
1. The clutch lever should be able to be moved 10–20 mm (0.4–0.8 in.) measured at the tip of the lever before the clutch begins to disengage.



Clutch lever free-play is measured at the end of the lever (2)

2. Loosen the clutch handlebar lever adjuster locknut and screw the adjuster into the lever housing to give as much slack in the cable as possible.

3. Using the lower clutch cable adjuster, align the clutch lifter lever with the index mark on the crankcase. On the MR175 and CR125, the center of the clutch cable lower end should be within 10 mm (0.4 in.) of the mark on the case.



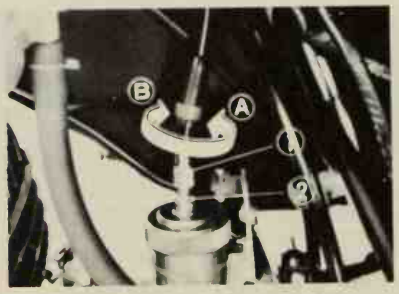
The clutch lifter lever (1) should be adjusted to align with the index mark on the crankcase (2) using the lower cable adjuster (3 and 4) (MT models and CR250)

The clutch lifter adjuster should be aligned within 10 mm of the index mark (1) using the lower cable adjuster (2 and 3) on CR125 models

4. Remove the clutch adjuster cap from the right crankcase cover. Loosen the pushrod adjuster locknut and back it off several turns.

5. Turn the adjuster screw in until it just touches the clutch pushrod (a slight resistance will be felt). Back off the screw ½ turn. Holding this adjustment, tighten the locknut.

Clutch pushrod adjuster locknut (1) and adjuster screw (2)



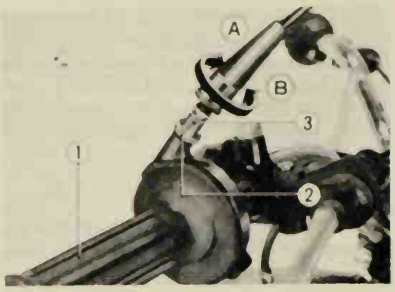
6. Adjust the cable with the handlebar adjuster to give the proper lever free-play, and check clutch operation.

THROTTLE CABLE

1. Throttle cable play should be adjusted *after* the idle speed. This procedure is given in "Tune-Up."

2. On MT models the oil pump cable must be adjusted after adjusting the throttle cable.

3. A cable adjuster is fitted to the top of the carburetor and another at the twist-grip. One throttle cable runs from the twist-grip to a junction box. There, it is connected to the oil pump cable and a shorter throttle cable which runs to the carburetor. Therefore each cable must be adjusted.

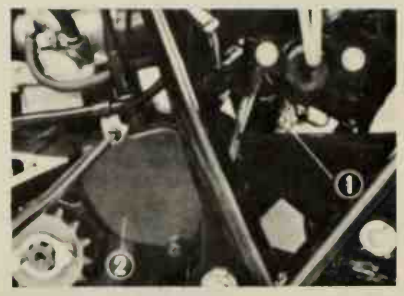


Adjusting the throttle cable free-play with the adjuster (1) and locknut (2). Turn the adjuster in direction "A" to decrease free-play, "B" to increase (MT models)

4. After setting the idle speed, use the adjuster on the carburetor cap to give 1 mm (0.04 in.) of cable free-play. This can be measured by gently lifting the cable out of the adjuster. It should come out no more than this amount before the throttle slide begins to rise. Loosen the locknut and screw the adjuster clockwise (in) to increase the slack and counterclockwise (out) to decrease it. Tighten the locknut.

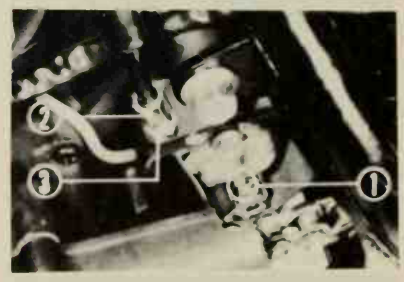
5. Adjust the long throttle cable with the adjuster at the twist-grip. This cable should be adjusted to give 0.5–1.0 mm (0.02–0.04 in.) of free-play (5°–10° of grip rotation).

6. On all models, after adjusting the throttle cable, start the engine and turn the forks slowly from lock-to-lock, noting any variation in idle speed. If the revs change, either the cables are adjusted too tightly, or are binding somewhere along their routing.



7. Adjust the oil pump cable.

Throttle cable twist-grip adjustment. Turn adjuster (3) in direction "A" to increase freeplay, "B" to decrease

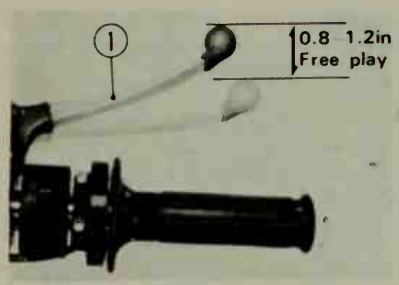


OIL PUMP CABLE (MT MODELS)

NOTE: *Adjust the throttle cable slack before attempting to adjust the oil pump cable. The oil pump cable should be adjusted whenever the throttle cable is adjusted.*

Oil line tank fitting (1) and oil pump case cover (2) (MT125)

1. Remove the oil pump case cover.
2. Fully close the throttle twist-grip.
3. Loosen the locknut on the adjuster above the oil pump, and turn the adjuster nut until the aligning marks on the oil pump body and the control lever are aligned.
4. Tighten the locknut on the adjuster. Open the throttle letting it snap to the closed position a few times. Recheck the oil pump cable adjustment.



Oil pump aligning marks, cable adjuster (2) and locknut (3)

FRONT BRAKE

1. Use the cable adjuster on the brake plate to allow about 20–30 mm (0.8–1.2 in.) of handlebar lever free-play before the linings contact the drum. This free-play is to be measured at the tip of the lever.

2. This free-play can be maintained as the shoes wear by using the adjuster at the handlebar lever.

Front brake cable free-play should be adjusted so that the lever moves 0.8–1.2 in. before the shoes contact the drum

REAR BRAKE

Use the adjusting nut on the end of the cable so that the brake pedal has 25 mm (1 in.) of free-play before the linings contact the drum.

BRAKE LIGHT SWITCH

The switch should be checked for operation after the brake is adjusted. The rear brake light switch is mounted in a slotted bracket and secured by locknuts. Moving the light switch up on the bracket allows the brake light to turn on sooner. Moving it down allows it to come on later. Generally, the brake light should come on just as the linings contact the drum.

FUEL SYSTEM

1. Fuel system maintenance involves cleaning the petcock and filter, cleaning or replacing the air cleaner, and cleaning the carburetor.

2. The carburetor should be removed, disassembled, and cleaned every 4,000 miles. The procedures are outlined in "Fuel Systems."

3. The petcock should be serviced every 3,000 miles. Shut the fuel off, then unscrew and remove the petcock sediment bowl. Take out the fuel filter screen. Clean the parts in a solvent and reinstall. Check for leaks.

AIR CLEANER SERVICE

The air cleaner should be serviced or replaced every 2–3,000 miles, depending on conditions.

1. Raise the seat, remove the wing nut from the air cleaner cover and remove the cover.

2. Remove the air cleaner element and wash it thoroughly in clean solvent.

3. When the air cleaner has dried completely, soak it in clean gear oil (SAE 80–SAE 90) and wring off excess oil.

4. Install the air cleaner, replace the air cleaner cover, and wing nut. On the MR175, and MT250, note that "FRONT" or "REAR" is marked on the element and must be installed correctly.

CR Models

The maintenance of CR Hondas is basically the same as for the MT series; however, since the CRs are intended for competition use only, the maintenance

Periodic Maintenance Schedule

This maintenance schedule is based upon average riding conditions. Machines subjected to severe use, or ridden in unusually dusty areas, require more frequent servicing.

	Regular Service Period Perform at every indicated month or mileage interval, whichever occurs first	
	6 Months	*12*
	3,000 Miles	*6,000*
Change transmission oil	•	
Spark plug—Clean and adjust gap or replace as necessary	•	
Contact point and ignition timing—Clean, check, and adjust or replace as necessary	•	
Polyurethane foam air filter element—Clean and oil (Service more frequently if operated in dusty area)	•	
Carburetor—Check, and adjust as necessary	•	
Oil pump operation—Check	•	
Cylinder head, cylinder, piston, piston rings and muffler—Decarbonize		•
Throttle operation—Inspect cable, check, and adjust free-play	•	
Clean oil tank filter		•
Clean fuel filter screen	•	
Clutch—Check operation, and adjust as necessary	•	
Brake shoes—Inspect, and replace if worn		•
Wheel rims and spokes—Check. Tighten spokes and true wheels, as necessary	•	
Inspect tires	•	
Change fork oil	•	
Swing arm bushing—Grease. Check for excessive looseness	•

Recommended Lubricants

Oil tank	Two-stroke oil Above 68° F: SAE 30, 10W-30, 20W 14° F–68° F: SAE 10W-30 Below 14° F: SAE 5W, 10W
Premix	Two-stroke oil, SAE 40
Transmission	SAE 10W-40 or SAE 10W-30 (all temperatures) SAE 30 (above 59° F) SAE 20 or 20W (32° F–59° F) SAE 10W (below 32° F)
Front forks	ATF
Drive chain	High-quality chain lube specifically developed for motorcycle drive chains
Wheel and steering head bearings	Lithium or Moly-based bearing grease
Cables	Light motor oil Graphite-based lubricant Molybdenum disulphide-based lubricant

procedures should be carried out much more often. Some standard values for parts replacement are as follows:

Piston rings	125 miles (2 races)
Spark plug	60 miles (1 race)
Transmission oil	60 miles (1 race)
Drive chain	190 miles (3 races)
Cables	190 miles (3 races)
Air cleaner	310 miles (5 races)
Contact points (250)	190 miles (3 races)

In addition, the motorcycle should be given a complete inspection before each race, some items to be inspected are:

Transmission Oil level
Drive chain for tension and lubrication
Axle nuts for tightness
Spokes for tightness
Rimlocks for tightness
Tire pressure
Cables for lubrication and free-play
Sprockets for wear
Frame for cracks: pay special attention to the steering lug, rear shock mounts, and engine mounts.

Check every possible part for looseness. Pay special attention to the following:

Engine mounting bolts
Cylinder head nuts
Footpeg nuts
Axle nuts
Upper and lower triple clamp pinch-bolts
Drive chain adjusters
Drive chain guide roller
Handlebar clamps
Rear shock mounting bolts

Check the fuel system for:
Dirt in the float bowl
Clogged fuel tank vent tube
Air cleaner for contamination
Air leaks
Smooth throttle operation

Tune-Up

NOTE: *Common tune-up procedures are explained in detail in "General Information."*

Contact Breaker Points

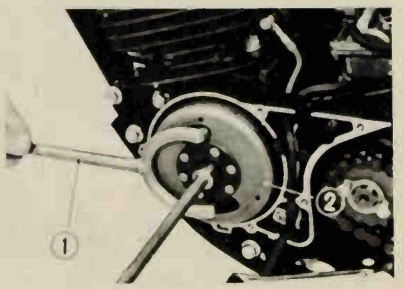
LOCATION

On all models (except the CDI CR125), the breaker points are located on the left-side of the crankshaft.

1. CR250: Remove the left crankcase cover to gain access to the points.

2. MT and MR models: Remove the magneto cover to gain access to the points. Cutouts are provided in the flywheel to allow the points to be cleaned and gapped.

REPLACEMENT



MT and MR Models

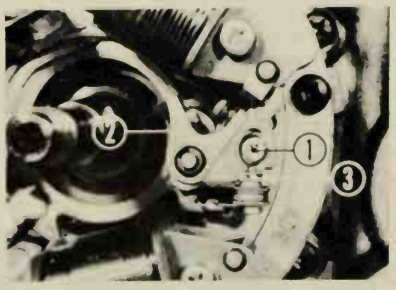
Two special tools are needed to replace the contact breaker points. A rotor holder is used to hold the magneto rotor from turning while the nut is removed, and a special puller is used to pull the rotor off its tapered shaft.

CAUTION: *The rotor puller is essential for this job. It is not wise to attempt to remove the rotor in any other way.*

1. Remove the left crankcase cover, after removing the pinch-bolt and pulling the gearshift lever off its shaft. The use of an impact driver to remove and install phillips head cover screws is recommended.

2. Holding the magneto rotor with the special tool, or a suitable substitute, loosen and remove the rotor nut.

Removing the magneto rotor nut while securing the rotor (2) with the special holder (1)



3. Tighten the puller into the rotor to remove it from the crankshaft. Note the key fitted to the crankshaft.

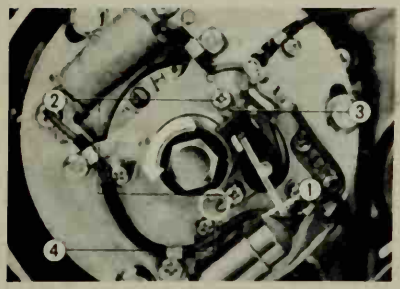
CAUTION: *Never use heat in an attempt to remove the rotor, since this may affect its magnetic properties. Handle the rotor with care: avoid dropping or striking it, as this, too, will affect its magnetism.*

Removing the magneto rotor with the factory puller

4. Disconnect the primary wire from the breaker point terminal, then remove the securing screw. Remove the old points set.

MT models breaker points: securing screw (1), breaker point movable arm (2), and primary wire terminal (3)

5. Clean the contact surfaces of the new set of points to remove any protective coating present. Install the points and reconnect the primary wire.



6. Grease or oil the crankshaft taper slightly before fitting the rotor to make removal easier next time. Line up the slot in the rotor with the key in the crankshaft. Push the rotor into place.

7. Replace the rotor nut and torque to 32.5–36.2 ft lbs while holding the rotor with the rotor holder. Check the ignition timing.

CR250

1. Remove the left crankcase cover.

2. Disconnect the primary wire at the breaker point terminal and remove the securing screws. Remove the old points.

Point gap (1), securing screws (2), point plate (3), and adjustment slot (4) (CR250)

3. Before installing new points, be sure to clean off the breaker point surfaces with a solvent to remove any protective coating.

4. Install the new points, tightening the securing screws lightly. Reconnect the terminal primary wire. Be sure that the small nut is firmly secured.

5. Adjust the point gap and recheck the ignition timing.

GAPPING (CR250)

Points should be filed (if necessary) or cleaned before gapping.

1. Remove the left crankcase cover. Clean and inspect the breaker points, replace if the points are badly pitted.

2. Remove the spark plug.

3. Using the bolt on the end of the crankshaft, rotate the crankshaft counterclockwise until the points are open to the maximum.

4. Using a feeler gauge measure the point gap. The correct gap is 0.3–0.5 mm (0.012–0.020 in.); if the gap is not in these limits, it will have to be corrected. The feeler gauge should be a light slip fit between the points.

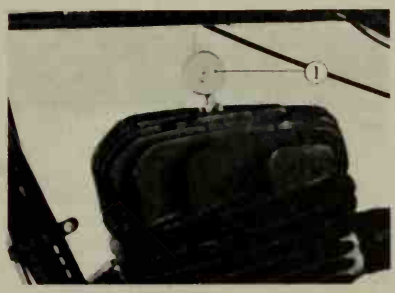
5. To adjust the gap, loosen the two point securing screws, then with a screwdriver in the adjusting slot in the bottom of the breaker plate, move the breaker plate until the gap is correct. Tighten the lockscrews and recheck the gap.

6. Whenever the point gap is checked or the points replaced, it is necessary to lubricate the point cam with a dab of grease or a drop of motor oil.

7. Whenever the point gap is changed the ignition timing will have to be checked as point gap adjustment will affect igniton timing.

Ignition Timing

NOTE: *Points must be cleaned and gapped (CR250) before checking the timing. Dirty points will cause inaccurate results.*



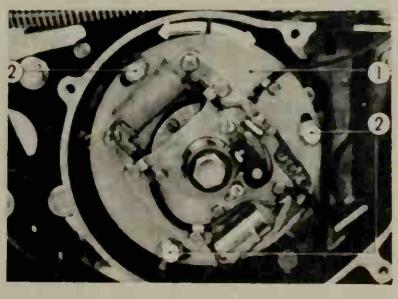
To properly time the engine, a device is needed to determine the piston position and another to find when the points open. A dial indicator is used for the first of these on the CR250; on MT models, timing marks are provided on the magneto rotor.

Point opening can be determined with a test light with a 6-volt battery and 25-35 watt bulb, or ohmmeter.

CR250

1. Remove the spark plug.

2. Install a dial gauge into the spark plug hole. Slowly rotate the engine until the gauge indicates its highest reading and begins to reverse. The highest reading is top dead center. Turn the engine a few degrees in either direction to recheck your finding. Then zero the gauge.



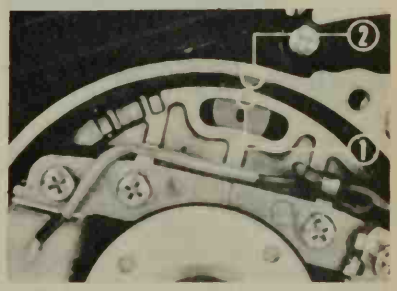
A dial gauge (1) is used to determine piston position (CR250)

3. Turn the crankshaft clockwise (backwards) until the dial gauge reads about 2 mm (0.080 in.) before top dead center (TDC). The points will be fully closed in this position.

4. Connect the ohmmeter so that the negative lead is connected to the engine or frame (ground) and the positive lead is connected to the points wire terminal. The ohmmeter should indicate zero resistance. Make sure that the meter is on the lowest possible scale.

5. Turn the crankshaft in the counterclockwise direction. When the dial gauge indicates the piston is at 1.5 mm (0.059 in.) BTDC, the points should just begin to open. At this point the ohmmeter will indicate an increase in resistance. If the points open before the correct position, the timing is too far advanced. If they open when the piston is past it, the timing is retarded.

6. If adjustment is necessary, set the piston at 1.5 mm (0.059 in.) BTDC as indicated on the dial gauge. Loosen the three base plate locking bolts and rotate the base plate until the timing is correct as indicated by the ohmmeter. To advance the timing, turn the base plate clockwise; to retard the timing, turn the base plate in the counterclockwise direction. Tighten the three locking bolts and check the timing as described in Step 5.

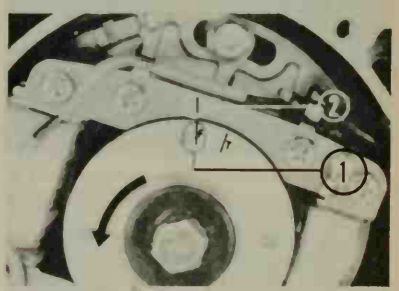


The base plate (1) is moved in either direction after loosening the three locking bolts (2) to adjust ignition timing (CR250)

CR125

The CR125 is equipped with a capacitive discharge ignition system (C.D.I.). This type of ignition does not use contact breaker points. To adjust the timing a stroboscopic timing light is necessary; also, some kind of tachometer will have to be used for best results.

1. Remove the left crankcase cover.



2. Remove the top bolt securing the stator to the crankcase. Check to see if the mark on the stator (this mark is exposed when the top bolt is removed) is aligned

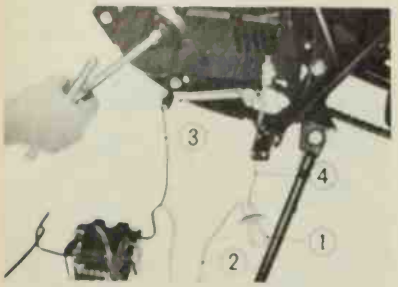
CR125: Align the mark on the stator (1) with the indicator on the crankcase (2)

with the indicator on the crankcase. If not, loosen the bottom stator securing bolt and rotate the stator until the marks are aligned. Tighten the two securing bolts.

3. Connect the timing light following the manufacturer's instructions. Check to see if the "F" mark on the rotor is aligned with the timing mark on the stator; at 6,000 rpm this will be 18° BTDC.

CR125: The "F" mark (1) should align with the mark on the stator (2) at 6,000 rpm when checking timing with a strobe light

4. If adjustment is necessary, loosen the two stator securing bolts. Using a screwdriver, placed in the grooves to the left of the top stator securing bolt, rotate the stator in either direction until the timing is correct. Turning the stator clockwise will advance the timing and rotating the stator counterclockwise will retard the timing. Tighten the two stator securing bolts and recheck the timing.

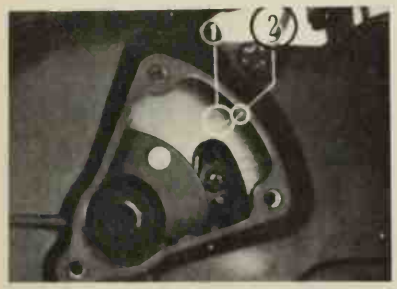


MT AND MR MODELS

On these models the ignition timing is adjusted by changing the point gap. A test light with a bulb the same wattage as the headlight and a 6 volt battery will be necessary to set the timing, while the best way to check the timing after it is set is with a stroboscopic timing light.

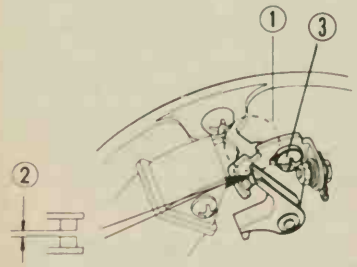
1. Remove the three screws from the

magneto cover on the left crankcase cover and remove the cover.



2. Disconnect the stator connection from the wiring harness. Connect one lead of the test light to the stator primary wire (black/white on the MT models or black/yellow on MR models) and the other lead to the positive terminal of the battery. Connect the negative terminal of the battery to any bare metal surface on the engine or frame.

A headlight bulb (1) connected to the black/white points primary wire (4), then to the positive battery terminal (2) and the battery to ground (3) is used to determine when the points open (MT models)



3. Remove the spark plug.

4. Rotate the crankshaft counterclockwise the light should go out just when the "F" mark on the rotor aligns with the indicator on the crankcase cover.

The "F" mark on the rotor should align with the indicator on the crankcase (2) at the instant the points open

5. If adjustment is necessary, place the "F" mark on the rotor in line with the indicator on the crankcase cover. Loosen the breaker plate screw and adjust the points so that they just open at that point. Tighten the breaker plate screw and recheck the timing as described in Step 4.

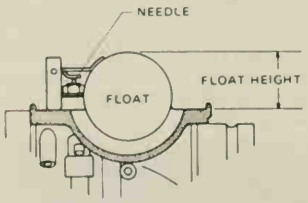
Points adjusting slot (1), point gap (2), and points securing screw (3) (MT models)

6. Check the point gap. If the maximum gap is not within 0.2–0.6 mm (0.008–0.024 in.) after the timing is set, replace the the points with a new set and readjust the timing.

7. Replace the spark plug and check the ignition timing with a stroboscopic timing light.

Carburetor

Three adjustments to be made to the carburetor are float height, idle mixture, and idle speed.



ADJUSTING FLOAT HEIGHT

1. Remove the carburetor as outlined in "Fuel Systems."

2. Turn the carburetor upside down, and remove the four float bowl screws carefully lifting off the float bowl.

3. Remove the float bowl gasket.

4. Float height can be measured with a steel rule, a vernier caliper, or with the Honda gauge. Float height is defined as the distance from the float bowl gasket

Float height adjustment is measured as shown

surface to the bottom of the float, when the tang of the float arm is just touching the float needle.

NOTE: *Lower the float down until the tang just contacts the float needle without compressing the spring-loaded plunger. Hold the float in this position, then measure the float height.*

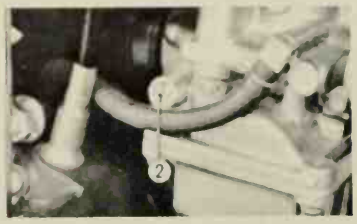
5. Compare the value obtained with the correct specification for your machine given at the end of this section. If the float height is too high or low, pull out the pin which holds the float in place, and bend the tang very slightly to correct the adjustment.

NOTE: *If float height is too high, bend the tang away from the carburetor body. If too low, bend it toward the carburetor body.*

6. Refit the float and recheck the adjustment.

CAUTION: *Bend only the float tang to make an adjustment. Do not bend the float arms. The floats must be level. If the floats show different heights, the float assembly should be replaced. This indicates that the float assembly has been mishandled.*

7. Float height will not be correct if the needle is worn, or if there is foreign matter on the needle seat. Refer to the "Fuel Systems" chapter for more information.



IDLE SPEED AND MIXTURE

NOTE: *These must be adjusted when the engine is at operating temperature.*

The throttle cable should be adjusted after making the idle speed and mixture adjustments. After adjusting the throttle cable, adjust the oil pump cable. Both of these operations are covered in "Maintenance."

the cable has enough slack to allow the throttle slide to be fully closed.

2. Screw the pilot air screw in (carefully) until it bottoms lightly, then turn it out the number of turns shown in the "Tune-Up Specifications" chart.

Pilot air adjustment screw (2)

3. Start the engine. When operating temperature is reached, adjust the throttle stop screw (if necessary) so that the engine idles as slowly as possible. Then turn the pilot air screw in or out until the engine runs smoothly. It should not be necessary to vary the air screw more than ½ turn in either direction from the given setting.

Idle adjustment (throttle stop) screw (1)

4. Adjust the throttle stop screw so that the engine idles at the desired rpm.

NOTE: *If proper idling cannot be obtained using this method, either the fuel system is clogged with dirt (check petcock, filter, float bowl), there is an air leak (manifold, cylinder head gasket, crankcase mating surfaces), or the engine has suffered mechanical damage (bad rings, leaking seals). The carburetor is the most likely source of poor idling. Disassemble, clean, and inspect it.*

5. After idle speed and mixture are set, adjust the throttle cable and oil pump cable as outlined in "Maintenance."

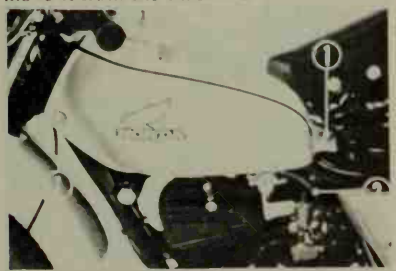
Engine and Transmission

NOTE *For engine component inspection techniques and procedures, refer to "Engine Rebuilding" under the General Information section.*

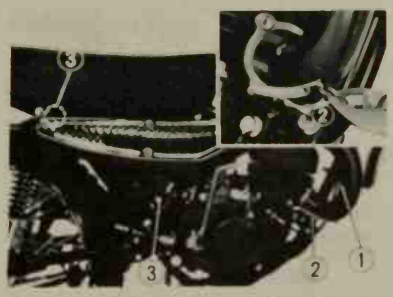
The following components may be serviced without removing the engine from the frame:

a. Cylinder and piston;
b. Clutch;
c. Carburetor;
d. Oil pump (MT series);
e. Magneto and electrics;
f. Gearshifter;
g. Kick-starter (250 models).



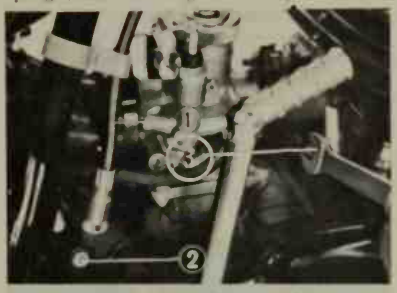
ENGINE REMOVAL AND INSTALLATION

MT125, CR125, and MR175

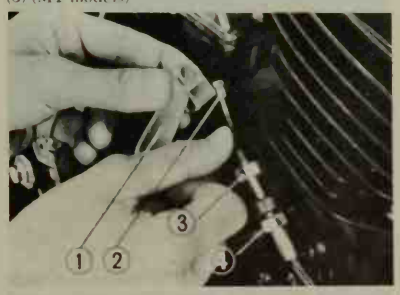


1. Drain the transmission oil. Open the seat; turn the fuel petcock OFF, and disconnect the fuel line from the petcock by expanding the spring clip, moving it an inch or so down the fuel line and pulling the fuel line from the petcock.

2. Remove the fuel tank rear mounting bolt, and the two mounting bolts located at the front of the tank. These should be removed complete with their collars and rubber bushing.

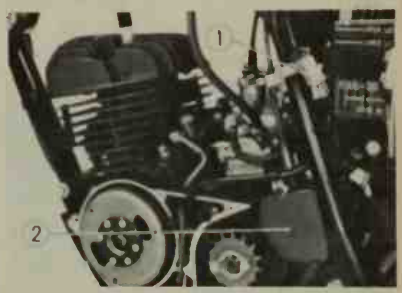


3. Disconnect the exhaust pipe springs. Remove the two muffler mounting bolts, then pull the exhaust pipe forward to free it from the cylinder and remove it from the machine.



Disconnect the fuel line (2), remove the securing bolts (1) and remove the gas tank

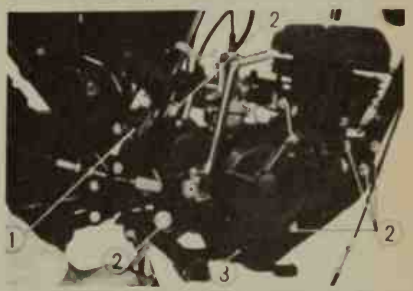
Remove the exhaust pipe (1) by disconnecting the springs (2) and removing the bolts (3)



Remove the tach cable securing screw (2) to pull out the tach cable (1). Remove the intake manifold bolts (3) (MT models)

Disconnecting the clutch cable from the clutch lifter lever (1)

4. MT only: remove the tach cable securing screw from the right rear of the crankcase, and disconnect the tach cable from the engine.



5. Disconnect the clutch cable from the engine by loosening the locknut on the cable adjuster at the engine and turning the adjuster in as far as possible. Pull

Magneto stator connector (1) and oil pump cover (2)

Disconnect the oil pump cable from the pump lever by removing the end pin (2); disconnect the line from the oil tank (arrow)

Disconnect the tank oil line (1), brake pedal (3) and engine mounting bolts (2)

the engine clutch lever back and disconnect the clutch cable from the lifter lever.

6. Remove the five 6 mm screws from the left crankcase cover and remove the cover.

7. Disconnect the stator connector from the wiring harness.

8. MT only: remove the two screws which secure the oil pump cover and remove the cover. Raise the oil pump control lever and pull out the cable end pin, freeing the cable from the lever. Unscrew the cable adjuster from the crankcase.

9. MT only: disconnect the oil line from the oil tank by expanding the spring clip and moving it back on the line until it clears the tank fitting. Then pull off the oil line, plugging the tank to prevent oil loss.

CAUTION: *Cover the open end of the oil line with a plastic bag secured with a rubber band to prevent dirt from entering the system. The oil pump cannot be disassembled for cleaning.*

10. Remove the drive chain masterlink spring clip, cover plate, and masterlink. Remove the drive chain from the motorcycle.

NOTE: *Install the masterlink on one end of the chain so that it will not be misplaced.*

11. Remove the nuts from the six engine mounting bolts, leaving the bolts in place.

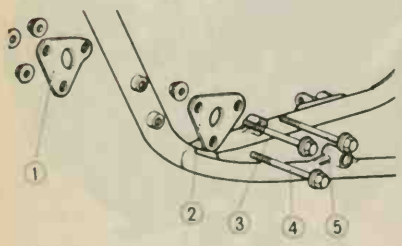
12. Remove the two bolts which secure the intake manifold to the cylinder, and pull the manifold and carburetor away from the cylinder.

NOTE: *It is not necessary to remove the carburetor from the manifold, but the carb and manifold must be placed out of the way to avoid damage when the engine is removed.*

13. Remove the rear brake pedal.

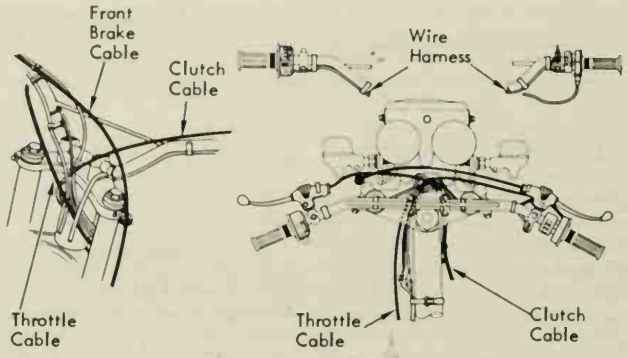
14. Disconnect the spark plug lead from the plug.

15. Slide the engine mounting bolts out from the left-side and remove the mounting plates.



CAUTION: *Take precautions that the bolt threads are not damaged as they are removed.*

16. Lift the engine out of the frame.



NOTE: *When the engine is removed, cover the intake port with a clean piece of rag to prevent the entry of foreign matter.*

17. Installation is basically the reverse of the removal procedure. Note the following points:

a. Install the engine mounting plates as shown, securing the skid plate to the mounting plate. The three front engine mounting bolts are of three different lengths and should be installed from the left-side of the frame in their proper positions;

Install the engine mounting plates positioned in this way

Correct cable routing (MT models)

b. When installing the gas tank, be sure that the cables are routed properly. After installation, check that all of the controls work without binding and especially that the throttle slide opens fully and returns to the fully closed position with no trouble. Wet the end of the fuel line with a little gasoline and slip it over the petcock fitting. Secure it with the spring clip;

e. The carburetor and battery overflow hoses should be routed between the engine and the swing arm and should end clear of all frame components;

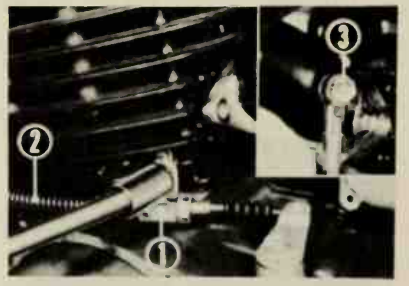
d. Install the drive chain, ensuring that the closed end of the masterlink spring clip faces the direction of chain rotation. Adjust the chain to the proper slack.

e. When installing the exhaust pipe, slide the pipe over the exhaust pipe joint making sure that the gap in the exhaust ring is facing *upward* (MT only). Loosely secure the two mounting bolts, and install the springs holding the exhaust pipe to the cylinder. Hook the ends of the springs to secure them in place. Now tighten the mounting bolts securely.

NOTE: *If the exhaust pipe joint has been removed from the cylinder, a new gasket should be used behind it.*

The gap in the exhaust pipe ring (1) should face upward (MT models)

MT250, CR250



1. Drain the transmission oil. Open the seat. Turn the fuel petcock OFF, and disconnnect the fuel line from the petcock by expanding the spring clip, moving it an inch or so down the line and pulling the fuel line from the petcock.

2. Remove the fuel tank rear mounting bolt, and the two mounting bolts located at the front of the tank. These should be removed complete with their collars and rubber bushing.

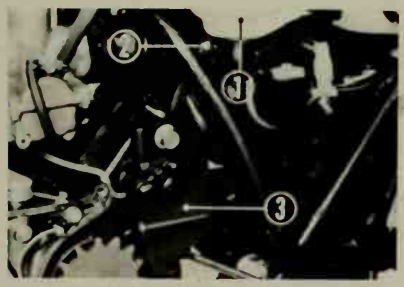
3. Disconnect the exhaust pipe springs. Remove the two muffler mounting bolts, then pull the exhaust pipe forward to free it from the cylinder, and remove it from the machine.

4. MT only: remove the tach cable mounting screw from the right rear of the crankcase, and disconnect the tach cable from the engine.

5. Disconnect the clutch cable by loosening the adjuster locknut and running the adjuster in to give as much slack as possible. Remove the clutch cable clamp stay and detach the cable end pin from the engine clutch lever. Remove the clutch cable from the engine.

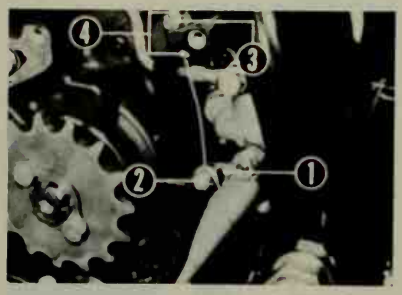
Removing the clutch cable stay from the engine (1), oil line banjo bolt (MT250)

6. MT only: disconnect the plastic oil feed line from the intake manifold.



CAUTION: *Cover the open end of the oil line with a plastic bag secured with a rubber band (include the banjo bolt and two washers) to prevent dirt from entering the system. The oil pump cannot be disassembled for cleaning.*

7. Remove the five 6 mm screws from the left crankcase cover and remove the cover.



8. Disconnect the stator connector from the wiring harness.

9. MT only: remove the two screws which secure the oil pump cover, and remove the cover. Raise the oil pump control lever and pull out the cable end pin, freeing the cable from the lever. Unscrew the cable adjuster from the crankcase.

10. MT only: disconnect the oil line from the oil tank by expanding the spring clip and moving it back on the line until it clears the tank fitting. Then pull off the

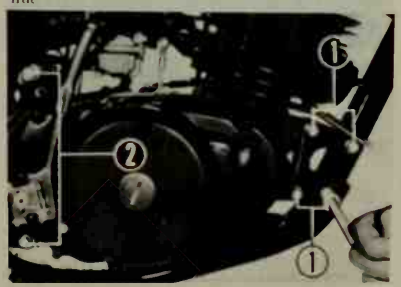
CAUTION: *Cover the open end of the oil line with a plastic bag secured with a rubber band to prevent dirt from entering the system. The oil pump cannot be disassembled for cleaning.*

11. MT only: remove the right rear foot rest and rear brake pedal.



12. Remove the drive chain masterlink spring clip, cover plate, and masterlink, and remove the drive chain from the motorcycle.

NOTE: *Install the masterlink on one end of the chain so that it will not be misplaced.*

13. Remove the nuts from the six engine mounting bolts, leaving the bolts in place.

Remove the footrest bolt (2), then the brake pedal nut

Front (1) and rear (2) engine mounting bolts

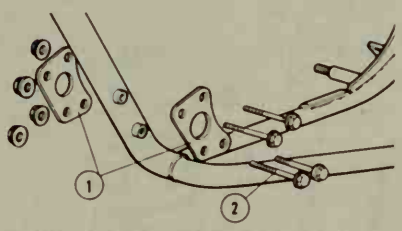
14. Remove the two bolts which secure the intake manifold to the cylinder, and pull the manifold and carburetor away from the cylinder.

NOTE: *It is not necessary to remove the carburetor from the manifold, but the carb and manifold must be placed out of the way to avoid damage when the engine is removed.*

15. Disconnect the spark plug lead from the plug.

16. Slide the engine mounting bolts out from the left-side and remove the mounting plates.

CAUTION: *Take precautions that the bolt threads are not damaged as they are removed.*



17. Lift the engine out of the frame.

NOTE: *When the engine is removed, cover the intake port with a clean piece of rag to prevent the entry of foreign matter.*

18. Installation is basically the reverse of the removal procedure. Note the following points:

a. Install the engine mounting plates as shown. The bolt holding the skid plate to the mounting plate is longer than the other three mounting bolts;

b. When installing the gas tank, be

Removal

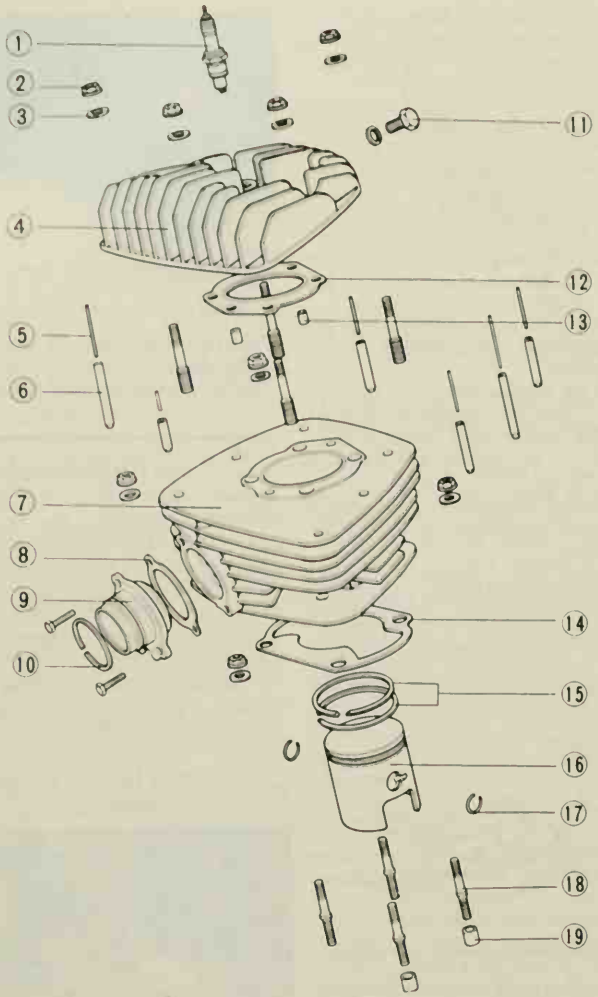
MT125, CR125

Clean the engine thoroughly before beginning.

1. Remove the fuel tank and the muffler as previously described in Steps 1–3 under "Engine Removal and Installation."

2. MT only: Remove the oil feed pipe from the cylinder.

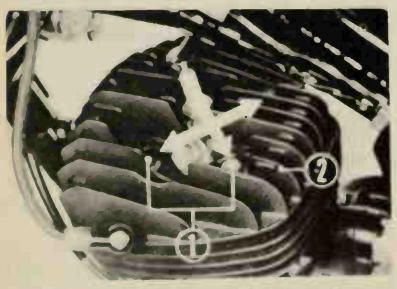
Disconnecting the oil line banjo bolt (1) and washers (3) from the cylinder



CAUTION: *Cover the open end of the oil line with a plastic bag secured with a rubber band (include the banjo bolt and the two washers) to prevent dirt from entering the system.*

3. Disconnect the spark plug lead and remove the plug.

4. Remove the two bolts securing the intake manifold. Loosen the air cleaner clamp on the carburetor and pull the manifold and carburetor away from the cylinder.



5. Loosen the four cylinder head nuts one-quarter turn at a time in an "X" pattern. When all the nuts are loose, remove them and their washers from the studs. Carefully lift off the cylinder head, and remove the head gasket beneath it as well.

NOTE: *If the cylinder head will not come off the cylinder, tap it at the bottom with a soft-faced mallet until it is free. Take care not to strike the cooling fins.*

6. Loosen the cylinder base nuts and remove them along with their washers. Turn the engine over until the piston is at top dead center, then lift the cylinder up and off the studs. When the cylinder spigot clears the crankcases, insert a clean, lint-free rag between the cylinder and crankcases. This will catch any piece of broken ring which may drop out when the piston comes out of the cylinder bore. Continue lifting up the cylinder until the pistons clear the bore, then place it in a safe place with the lower end up to await service.

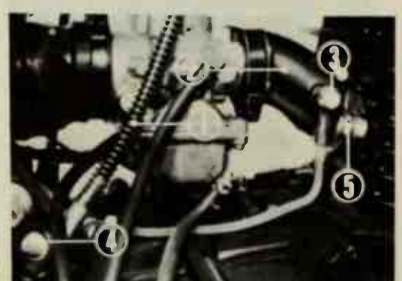
Remove the cylinder base nuts, and remove the cylinder (1)

7. Remove the wrist pin circlips with needlenose pliers. The rag should remain in place while doing this to prevent one of the circlips from falling into the crankcase.

Grasp the piston with one hand, and push out the wrist pin with a suitable drift. If the pin will not come out, the piston crown may be heated, evenly and gently, with a propane torch. If the pin still resists, it is advisable to use a special tool to remove it. This consists of a steel band or bands which fit around the piston while an attached screw device is used to push out the pin.

Stuff a rag into the crankcase (1) before removing the wrist pin circlips (2) from the piston (3)

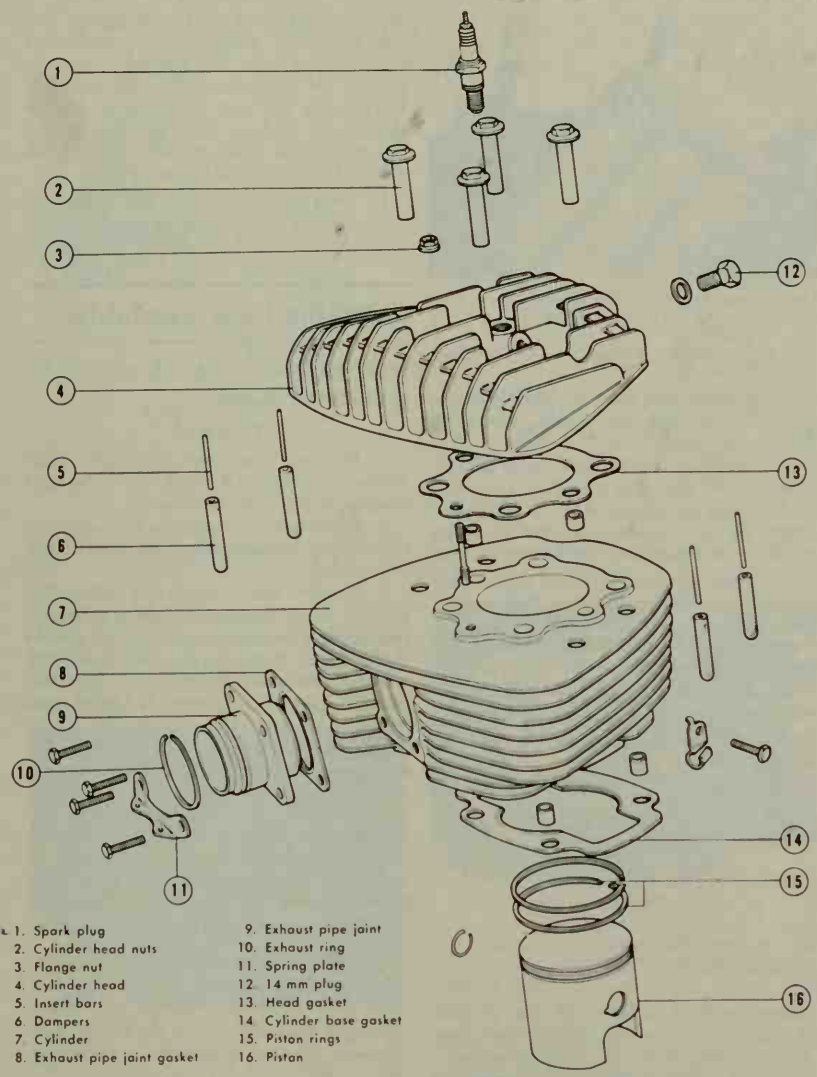
8. When the wrist pin is about ¾ in. out of the piston, grasp the exposed end with needlenose pliers, and pull it out until it is clear of the connecting rod. Remove the piston from the engine.



CAUTION: *Never strike the wrist pin or attempt to use force to drive it out. The connecting rod may be bent in the attempt.*

9. Take out the needle bearing from the connecting rod small end.

MT250, CR250, AND MR175



Clean the engine thoroughly before beginning. The areas around the cylinder head and cylinder base gaskets are particularly important.

1. Remove the gas tank and muffler as described in Steps 1–3 under "Engine Removal and Installation."
2. MT only: Remove the oil feed line from the intake manifold.

Disconnect the tach cable (1) after removing the securing screw (4); remove the banjo bolt (3), manifold bolts (5), and manifold (2)

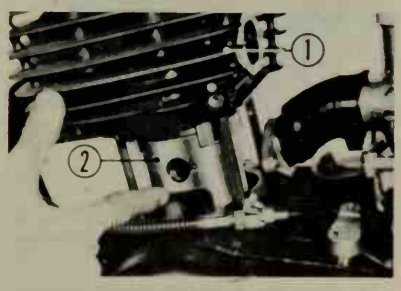
4. Loosen the carburetor air cleaner clamp; remove the two bolts which secure the intake manifold, and pull the carburetor and manifold away from the cylinder. Remove the clutch cable from the cylinder clip.



5. Remove the 6 mm nut from the head (MT and CR models). Loosen the four 8 mm cylinder head nuts one-quarter turn at a time, and in an "X" pattern. When all the nuts are loose, remove them and their washers from the studs. Carefully lift off the cylinder head and remove the head gasket beneath it as well.

NOTE: *If the head does not separate easily from the cylinder it may be necessary to tap it at the bottom with a soft-faced mallet to free it. Take care not to strike the cooling fins.*

6. Turn the engine over until the piston is at top dead center then lift the cylinder up until the cylinder spigot clears the crankcases. Insert a clean, lint-free rag between the cylinder and crankcase. Continue lifting the cylinder until the piston comes out of the bore. Place the cylinder in a safe place to await service with the bottom up.

Remove the cylinder head set bolt (2), then the cylinder head bolts (1)

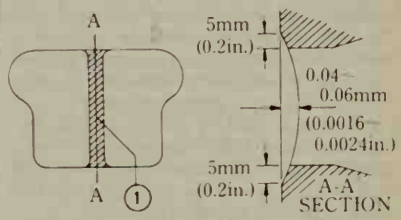
Removing the cylinder

7. Remove the piston wrist pin circlips with needlenose pliers. The rag should remain in place while doing this to prevent one of the circlips from falling into the crankcase. Grasp the piston with one hand and push out the wrist pin with a suitable drift. If the pin will not come out, the piston crown may be heated, evenly and gently, with a propane torch. If the pin still resists, it is advisable to use the shop wrist pin removal tool. This consists of a steel band or bands which fit around the piston while the attached screw device is used to push out the pin.

8. When the wrist pin is about ¾ in. out of the piston, grasp the exposed end with a needlenose pliers, and pull it out until it is clear of the connecting rod. Remove the piston from the engine.

CAUTION: *Never strike the wrist pin or attempt to use force to drive it out. The connecting rod may be bent in the attempt.*

9. Remove the small end needle bearing from the connecting rod.



Inspection

1. Piston diameter is measured 8 mm from the bottom edge of the skirt, perpendicular to the wrist pin.

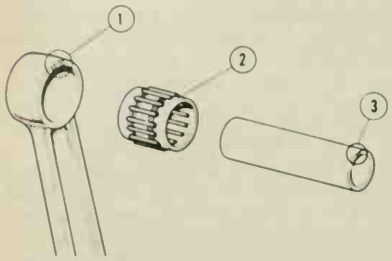
2. Cylinder bore is to be measured in four places: at the top, bottom, and just above the intake and exhaust ports.

3. Refer to the charts at the end of this section for clearances and specifications of top end components.

NOTE: *After boring the cylinder, or whenever the rings are replaced, the cylinder should be honed so that a crosshatched finish is produced. Also, it is important that the edges of the ports be bevelled slightly. This can be done with some emery cloth. Use an oil stone or a small file to relieve the port ribs to the dimensions shown in the illustration.*

Port ribs (1) should be relieved as shown if the cylinder is bored

SMALL END BEARING SELECTION



MR and CR Models

The bearings are color coded either red, blue, or white while the connecting rod and wrist pin are marked by notches.

NOTE: *All 125 cc models have one notch on the wrist pin.*

If, for example, the wrist pin is notched, and the connecting rod has two

notches, a blue con rod bearing should be used.

MR Models

The small end bearing is identified by the number of notches on the top of the connecting rod. If the bearing must be replaced, refer to the accompanying chart for the correct part no. of the replacement bearing.

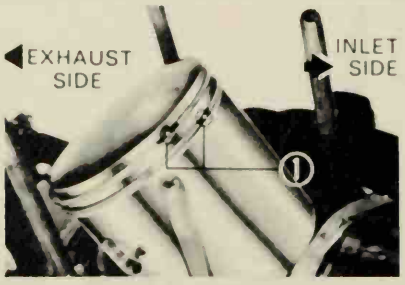
CYLINDER HEAD, CYLINDER, AND PISTON

Installation (All Models)

1. Refit the piston rings to the piston; note that on CR and MT models the top ring is the "Keystone" type. The top and bottom rings look almost identical but they are not interchangeable except on MR models as the top piston ring groove is also bevelled. Before installing the top ring, hold it on a straightedge; the bevelled edge should be clearly visible. Install the rings with the manufacturer's stamped mark (stamped near the end gap) facing *up*, and the end gap over the locating pins in the grooves.



On MR models, both rings are "Keystone" type.

2. Refit the wrist pin to the piston. Insert the wrist pin into the piston until about ⅛ in. of the wrist pin is visible pro-

3. Place the piston over the connecting rod with the locating pins in the ring grooves facing the *rear* of the engine.

4. Carefully line up the wrist pin with the connecting rod small end needle bearing, and push the wrist pin through until it is centered between the circlip grooves.

5. New circlips must be used. Refit them with needlenose pliers. Be sure

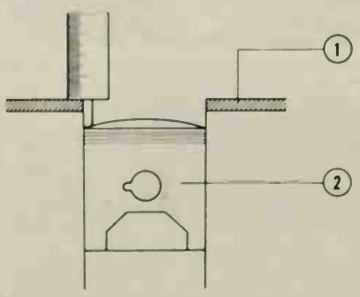
The locating pins (1) must face toward the rear of the engine when the piston is installed

that the circlips are firmly seated in their grooves.

6. Lightly lubricate the wrist pin, the piston rings, and the piston skirt with two-stroke oil.

7. Install a new cylinder base gasket, making sure that it is installed correctly.

8. Place the piston at top dead center. Align the piston rings so that the ring ends are directly over the locating pins.



9. Take up the cylinder, make sure that the cylinder walls are lightly coated with oil and fit the cylinder on the crankcase studs (250 and 175 cc mocels), or over top of the piston (125 cc models).

10. Lower the cylinder over the piston while compressing the piston rings with your fingers until the piston has fully entered the bore.

11. Make sure that the cylinder is properly seated in the crankcase. On 125 cc models, replace and tighten the cylinder base nuts in an "X" pattern in increments of a few ft lbs until the proper torque of 14.5–16.6 ft lbs is reached.

12. Install the cylinder head gasket, placing a thin coat of oil on both sides to ensure a good seal.

13. CR models only: measure the clearance between the top of the head gasket and the top of the piston crown with the piston at top dead center. The clearance on the CR125 should be 1.3–1.7 mm (0.051–0.067 in.), and on the CR250, 2.0–2.5 mm (0.079–0.098 in.).

CR models: Measure the distance from the top of the head gasket (1) to the top of the piston (2) when the piston is at TDC

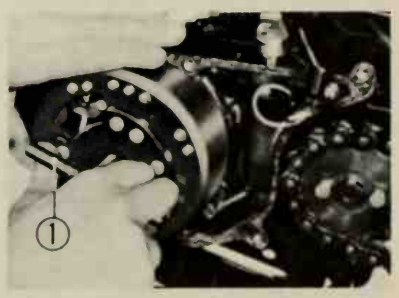
14. Refit the cylinder head, cylinder head washers and nuts and tighten the nuts in an "X" pattern in increments of 2–3 ft lbs to the proper torque. Torque for 125 cc models is 14.5–16.6 ft lbs; for the 250 and 175 models, torque should be 14.5–18.1 ft lbs. The 6 mm flange nut on 250 models should be torqued to 7.2–9.4 ft lbs.

15. The remainder of the assembly procedure is the reverse of disassembly.

Engine Case Assemblies

MAGNETO/ALTERNATOR ASSEMBLY

MT and MR Models



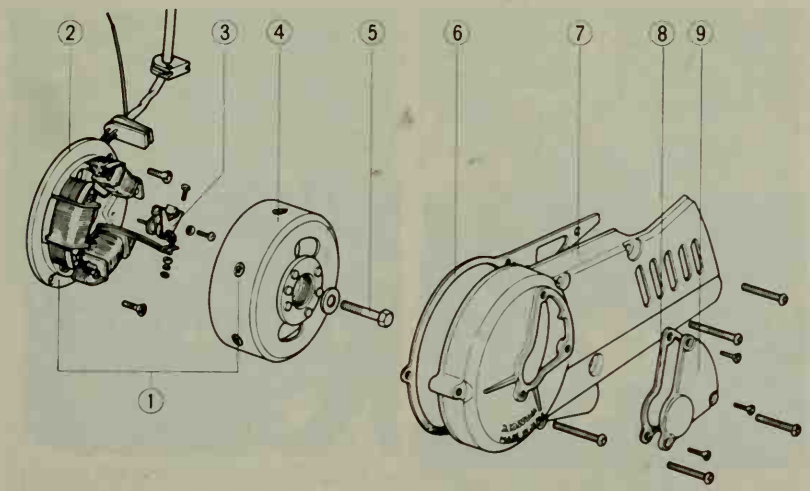
REMOVAL

1. Remove the five phillips head screws from the left crankcase cover and remove the crankcase cover.

2. Disconnect the electrical leads from the wiring harness near the rear of the fuel tank.

3. Remove the bolt (on the 125) or the nut (on the 175 and 250) and washer securing the magneto rotor to the crankshaft. When removing the bolt (or nut) it will be necessary to hold the rotor stationary. The use of a rotor holder is preferred; however, if the engine is still in the frame, it is possible to hold the rotor stationary by placing the engine in gear and applying the rear brake. If the engine has been removed, the rotor can be secured, after placing the transmission in gear, by holding the countershaft sprocket with the special tool, or by looping a length of old drive chain around the sprocket and locking the chain in a vise.

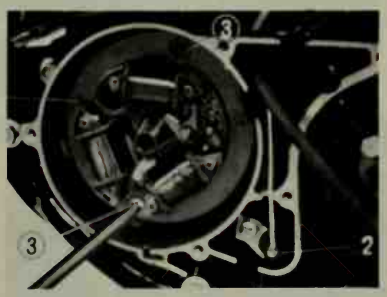
CAUTION: *Do not attempt to secure the rotor by using a screwdriver or the like held against one of the coils through the windows in the rotor, and do not attempt to pry the rotor from the crankshaft. Either of these approaches may result in damage to the rotor or stator.*



Removing the rotor with the special puller (1)

4. Screw the rotor puller (Tool No. 07933-0010000) for the 125 and 175 models or (Tool No. 07933-3580000) for the 250 into the rotor and pull the rotor from the crankshaft. Remove the woodruff key from the crankshaft using a punch if necessary.

5. Remove the phillips head screws securing the stator plate to the crankcase and remove the stator.



6. MT models only: remove the screw

Disconnect the neutral switch wire (2), remove the stator (1) by removing the stator securing screws (3)

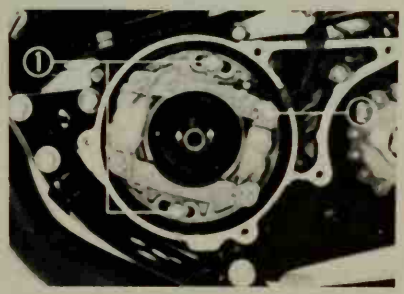
INSTALLATION

Installation is in the reverse order of removal.

1. Make sure that no metal objects have become attached to the rotor magnets before installing the rotor, and be sure that the key and the key way line up before placing the rotor on the crankshaft. A bit of grease smeared onto the crankshaft taper will ensure easy removal of the rotor next time.

2. Draw the rotor down on the crankshaft with the mounting nut (or bolt on 125 models). Do not attempt to drive the rotor onto the crankshaft by force.

3. Be sure that the rotor does not rub on the stator as it rotates.



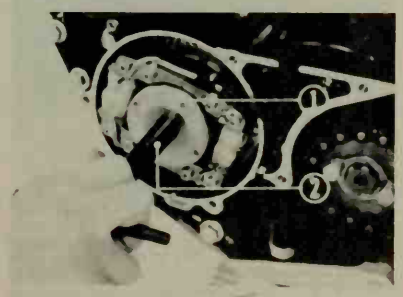
4. Check the ignition timing.

CR125

REMOVAL

1. Remove the five phillips head screws from the left crankcase cover and remove the cover.

2. Disconnect the magneto electrical lead from the wiring harness under the fuel tank.



Stator securing bolts (1) and stator (2)

3. Remove the rotor securing bolt and remove the rotor with the special rotor pulling bolt supplied in the Honda tool kit.

NOTE: *When removing the rotor bolt it will be necessary to keep the crankshaft from rotating. If the engine is in the frame place the engine in High gear and apply the rear brake while removing the bolt. If the engine is out of the frame, place it in High gear and hold the countershaft sprocket with the factory Tool No. 07933-2160000 or by looping an old length of drive chain around the sprocket and locking the chain in a vise.*

4. Remove the two bolts securing the stator to the crankcase and remove the stator. Refer to "Electrical System" for component tests.

Removing the rotor (1) with the puller (2) (CR125)

INSTALLATION

1. Installation is in the reverse order of the removal procedure, however note the following points:

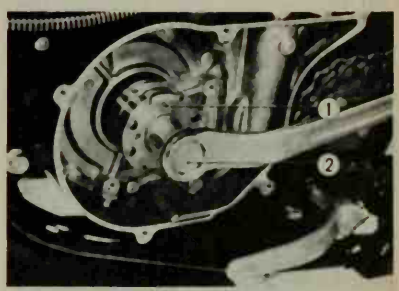
When installing the stator, line up the stator and crankcase marks to give a rough approximation of ignition timing;

a. Make sure that no metal objects have become attached to the rotor magnets before installing the rotor, and be sure that the key and the key way line up before placing the rotor on the crankshaft. Some grease applied to the crankshaft taper will make rotor removal easier the next time;

b. Draw the rotor down on the crankshaft with the mounting bolt. Do not attempt to drive the rotor onto the crankshaft by force.

c. Be sure that the rotor does not rub on the stator as it turns.

d. Check the ignition timing.



CR250

REMOVAL

1. Remove the five phillips head screws from the left crankcase cover and remove the cover.

2. Disconnect the electrical leads from the wiring harness.

3. Remove the three stator securing screws, and remove the stator from the engine.

Removing the rotor (1) with the removal bolt (2) (CR250)

4. Remove the securing bolt from the rotor holding the crankshaft as described in the previous section (Step 3); then remove the rotor with the special bolt supplied in the Honda tool kit.

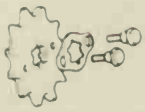
INSTALLATION

1. Installation is in the reverse order of the removal procedure, however note the following points:

a. Make sure that no metal objects have become attached to the rotor magnets before installing the rotor, and be sure that the key and the key way line up before placing the rotor on the crankshaft.

b. Draw the rotor down on the crankshaft with the mounting bolt. Do not attempt to drive the rotor onto the crankshaft by force.

c. Be sure that the rotor does not rub on the stator as it turns.



d. Check the ignition timing.

COUNTERSHAFT SPROCKET

All Models

To remove the countershaft sprocket,

remove the two bolts from the sprocket and rotate the lockplate until the tabs on the plate line up with the slots in the countershaft. Pull the lockplate and sprocket from the countershaft. When refitting the sprocket, install the lockplate on the countershaft, then rotate the plate until the bolt holes line up. Install the two bolts and torque to 5.8–8.7 ft lbs.

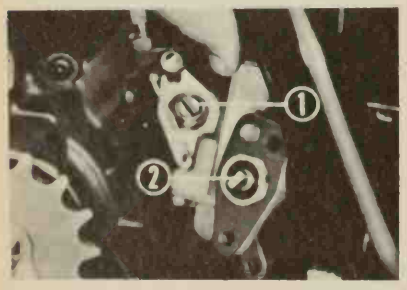
OIL PUMP

MT Models

REMOVAL

NOTE: *The oil pump should never be removed unless necessary. It cannot be rebuilt, and therefore must be replaced if defective.*



1. Disconnect the chain; remove the left crankcase cover, and the oil pump case cover.
2. Remove the left-side plastic cover, and disconnect the oil line from the oil tank. Plug the tank to prevent oil leakage.
3. Raise the pump control lever, remove the control cable end pin, and disconnect the cable from the pump.
4. Remove the banjo bolt and two mounting screws from the pump. Remove the pump by pulling it up and out.

Remove the oil pump (1) after disconnecting the banjo bolt (2) and mounting screws (3)

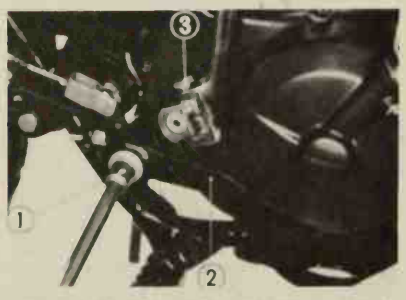
INSTALLATION

1. Slip the oil pump feed line over the fitting on the oil pump and secure with a spring clip.
2. Pass the oil line through the inlet grommet hole and pull it towards the oil tank.
3. Fit the pump drive into the opening in the crankcase. Be sure to line up the slot on the driveshaft with the tab on the oil pump. Push the pump on by hand until it is perfectly mated with the crankcase, and secure it with the two mounting screws.
4. Connect the engine oil feed line to the pump with the banjo bolt.

When installing the pump, the slot in the driveshaft (1) must engage the tab on the oil pump (2)

Ensure that the oil tank line (2) is secured with a spring clip (1)

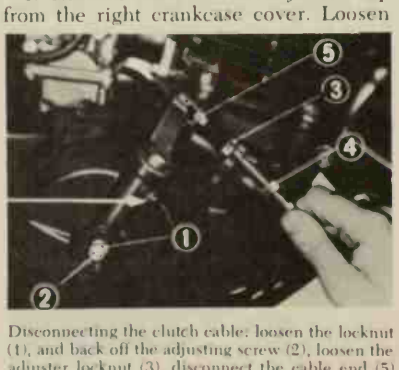
5. Connect the oil line to the oil tank and secure it with a spring clip.
6. Connect the oil pump control cable.



Bleed the oil pump as described in "Lubrication System." Adjust the oil pump cable so that the lines on the pump and on the control lever are aligned when the throttle is closed.

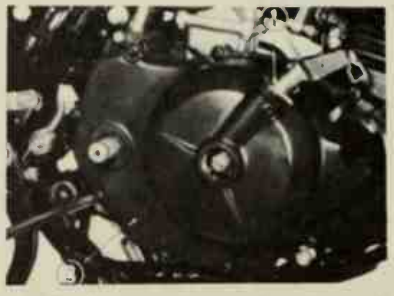
CLUTCH

125 and 175 Models



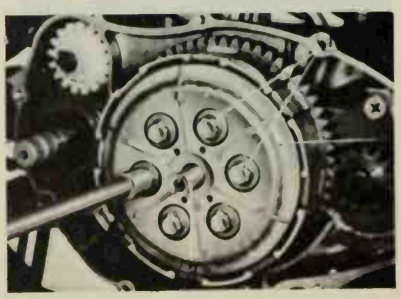
REMOVAL

1. Drain the transmission oil.
2. Remove the rear brake pedal pivot shaft, and rear brake pedal. Remove the pinch-bolt from the kick-starter and remove the kick-starter from its shaft.

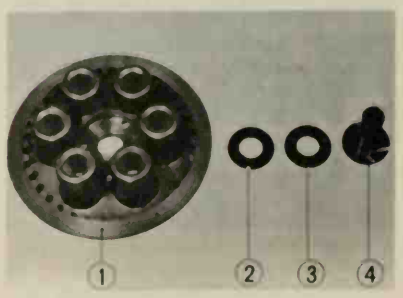


Removing the brake pedal pivot bolt (1). Remove the kick-starter after taking off the pinch-bolt (3)

3. Remove the clutch adjuster cap from the right crankcase cover. Loosen the locknut on the adjuster and back off the adjuster by turning it counterclockwise.
4. Loosen the locknut and adjusting nut on the clutch cable adjuster, and disconnect the clutch cable from the lever on the right crankcase cover.



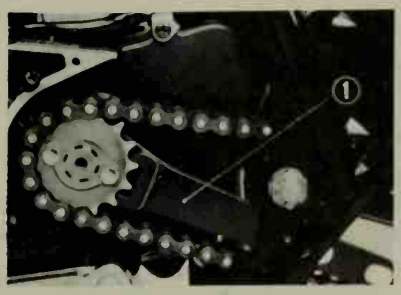
Disconnecting the clutch cable: loosen the locknut (1), and back off the adjusting screw (2), loosen the adjuster locknut (3), disconnect the cable end (5) from the lever. The arrow indicates the special 6 mm bolt



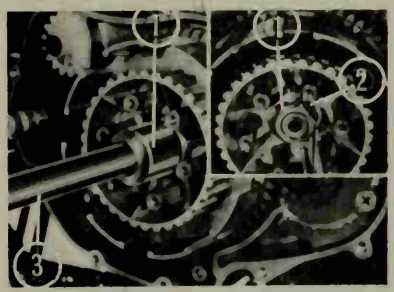
Pull the lifter shaft out about ½ its total length (1 and 2), remove the cover screws and the cover (3)

5. Unhook the return spring from the lifter shaft, then remove the special 6 mm bolt from the cover.
6. Remove the ten phillips head cover mounting screws from the right crankcase cover. An impact driver should be used. While keeping the lifter shaft pulled up about ½ its total length, remove the right crankcase cover and cover gasket.

NOTE: *Place a pan beneath the cover before removing it to catch any remaining oil.*



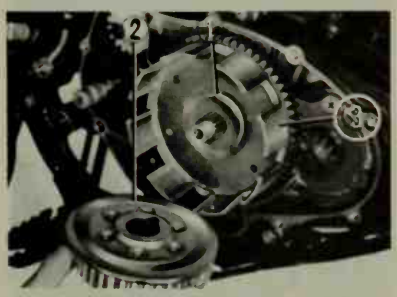
Removing the clutch pressure plate bolts (1), the pressure plate (2) and pushrod (3)



Pressure plate (1), 12.5 mm thrust washer (2), thrust needle bearing (3), clutch pushrod (4) (125 models)

7. Loosen the six clutch pressure plate bolts evenly to avoid deforming the pressure plate, then remove the springs, washers, and pressure plate. Remove the clutch push rod, thrust needle bearing, and 12.5 mm thrust washer from the pressure plate.

Countershaft sprocket holder in place

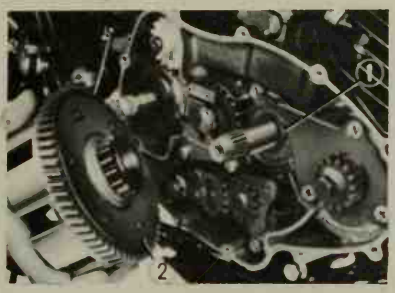


8. Secure the countershaft sprocket, as illustrated, using either the sprocket holder (Tool No. 07922-3570000) or a suitable substitute. Place the transmission in First gear, bend back the locking tabs on the clutch hub 16 mm lockwasher and remove the locknut with a 22 mm socket.

Bend down the locking tab on the washer (2), and remove the locknut (1)

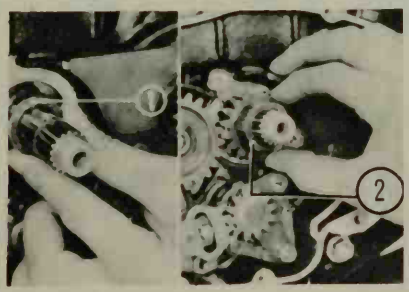
NOTE: *If the engine is still in the frame the countershaft sprocket can be held by placing the transmission in gear and applying the rear brake while unscrewing the clutch hub locknut. If it has been removed, a length of old drive chain can be looped around the sprocket and the chain locked in a vise.*

9. Remove the clutch hub and the friction discs and steel plates; then remove the 20 mm splined washer and the clutch outer housing, kick-starter gear, and the 20 mm thrust washer.



Splined thrust washer (1), clutch hub (2), and clutch outer housing (3)

Installation

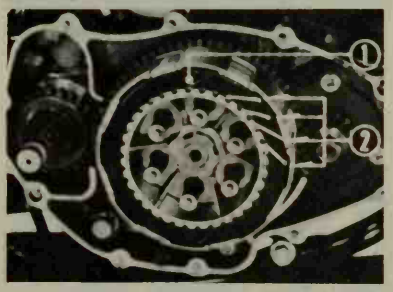


1. Installation is in the reverse order of removal.

2. 125's only: Install the 20 mm thrust washer on the mainshaft, then install the clutch outer housing so that it is in mesh with the primary drive gear and the starter idle gear.

3. CR models only: Install the 20 mm thrust washer and starter shaft on the mainshaft, then install the clutch housing onto the starter shaft.

Remove the clutch housing and kick-starter gear (2) and 20 mm thrust washer (1)

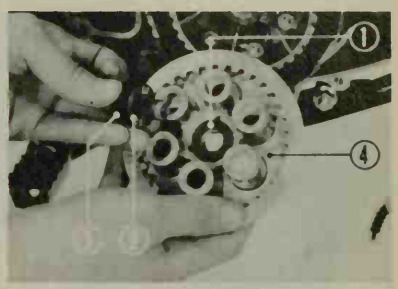


CR models: Install the thrust washer (1) and the starter shaft (2)

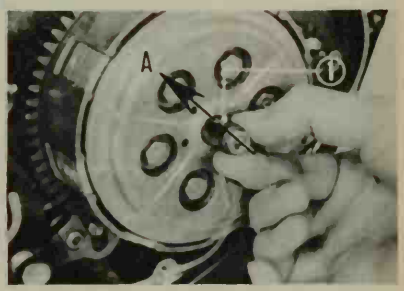
4. Install and secure the clutch hub making sure that the splined thrust washer is in place, and the locking tab of the lockwasher is seated in the attaching hole in the clutch hub or in the groove in the mainshaft on CR models. Secure the locknut and bend the side of the lockwasher opposite the locking tab up against the flat side of the nut.

The locknut should be torqued to 28.9–36.2 ft lbs.

5. Install a friction disc, then a steel plate, then a friction disc, and so on, making sure that the oil grooves on the disc are positioned as shown in the accompanying illustration.

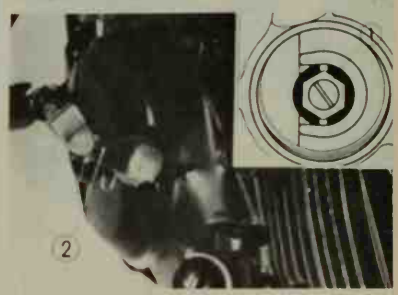


Make sure that the oil grooves in the friction discs (1) are positioned as shown (2)



6. Install the 12.5 mm thrust washer, the roller bearing thrust washer, and the clutch pushrod in the pressure plate. Install the adjusting screw and locknut into the pushrod.

7. Install the pressure plate, clutch springs, spring washers, and pressure plate bolts. Torque the pressure plate bolts to 5.8–8.7 ft lbs. Do this gradually, and in a cross pattern. Install a new cover gasket.



8. With the pushrod positioned as shown, install the right crankcase cover holding the lifter shaft out of the cover by ½ its length. Refit and secure the cover screws.

Fit the thrust washer (1), needle bearing thrust washer (2), and pushrod (3) to the pressure plate (4)

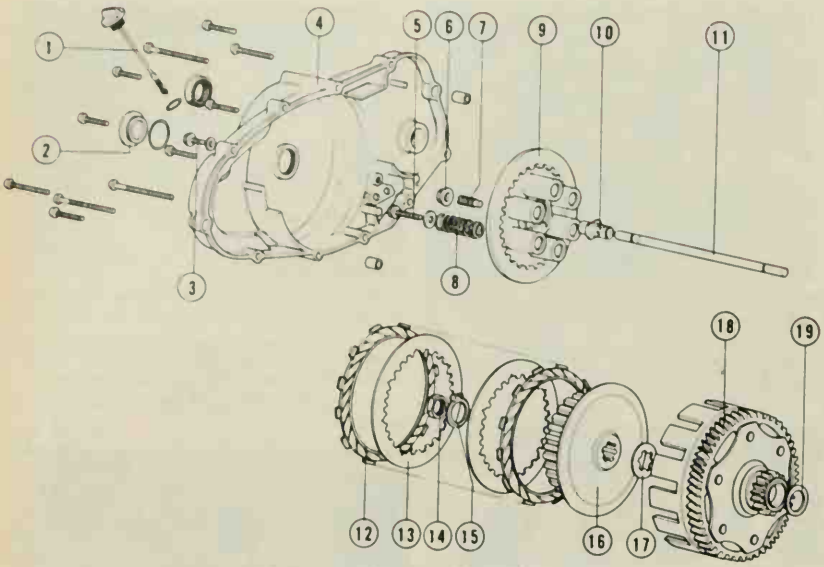
Position the pushrod (1) as shown before installing the right crankcase cover

When installing the crankcase cover, the clutch lever (2) should be positioned as shown, while the pushrod (1) should appear as shown in the inset when viewed from the clutch adjustment plug hole

250 Models

Removal

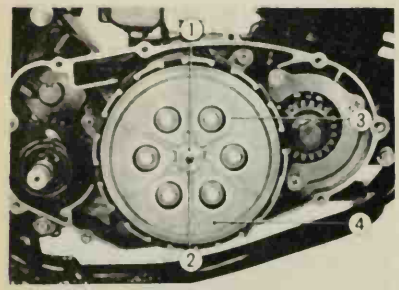
1. Drain the transmission oil.



2. Remove the right foot rest and brake pedal. Remove the pinch-bolt from the kick-starter and remove the kick-starter from its shaft.

3. Remove the eight phillips head mounting screws from the right crankcase cover and remove the cover and gasket. Use an impact driver to remove the screws.

NOTE: *When the cover is removed the oil remaining in the right-side will drip out, therefore it is recommended that you remove the skid plate and place a pan under the right-side of the engine to collect the oil.*



4. Loosen the six clutch pressure plate bolts evenly to avoid deforming the pressure plate, then remove the washers, clutch springs, and pressure plate.

5. Remove the clutch adjuster locknut, adjuster screw, and pressure plate center

6. Secure the countershaft sprocket using either the sprocket holder (Tool No. 07922-3570000) or a suitable substitute. Place the transmission in First gear, bend back the locking tabs on the 18 mm lockwasher and remove the locknut from the hub center with a 27 mm socket.

NOTE: *If the engine is in the frame, the countershaft sprocket can be secured by placing the transmission in gear and applying the rear brake. If removed from the frame, a length of old drive chain can be looped around the sprocket and clamped in a vise.*

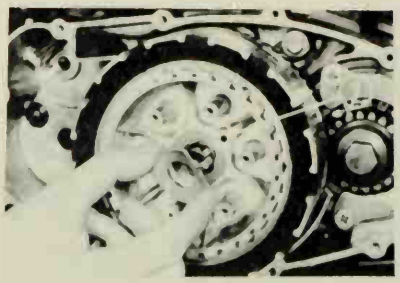
7. Remove the clutch hub and the friction discs and plates; then remove the 22 mm splined thrust washer and clutch housing, and 25 mm thrust washer (MT only).

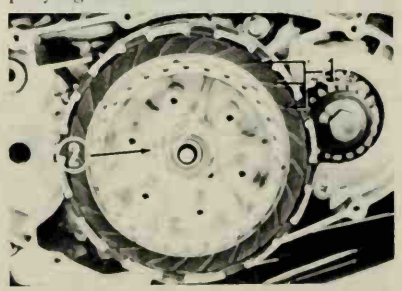


8. CR models only: Remove the two needle roller bearings, 29 mm spacer and 25 mm thrust washer.

Remove the needle roller bearings (1), 29 mm spacer (2), and thrust washer (3) (CR250)

Installation

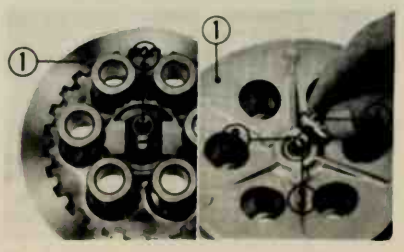
1. Assembly is in the reverse order of disassembly. Use new gaskets and lockwashers.



Engage the locking tab on the lockwasher (1) into the attaching hole in the clutch hub (2)

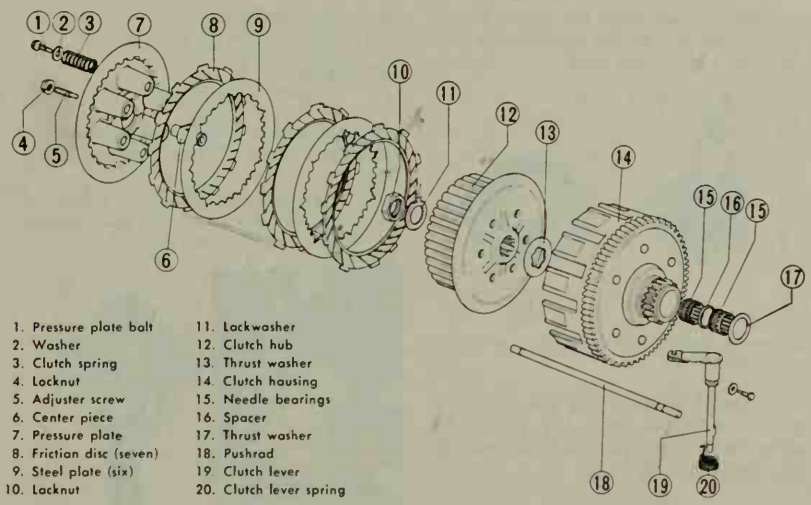
2. Position the thrust washer on the mainshaft, then install the clutch housing so that it is in mesh with the primary drive gear and the starter idler gear.

3. Install and secure the clutch hub center making sure that the splined thrust washer is in place, and that the locking tab of the lockwasher is seated in the attaching hole in the clutch hub. Secure the locknut and bend the side of the lockwasher opposite the locking tab up against a flat side of the nut.



The locknut should be torqued to 28.9–32.5 ft lbs.

4. Install a friction disc, then a steel plate, then a friction disc, and so on, making sure that the oil grooves on the disc are positioned as shown in the accompanying illustration.



Be sure to bend up the tab on the lockwasher (2) after tightening the hub nut. Install the friction discs so that the oil grooves are positioned as shown (2)

5. Install the center piece into the pressure plate, then install the adjusting screw and locknut on the pressure plate. Install the clutch pushrod (if it has been removed) with the spherical end towards the pressure plate (the other end is flat).

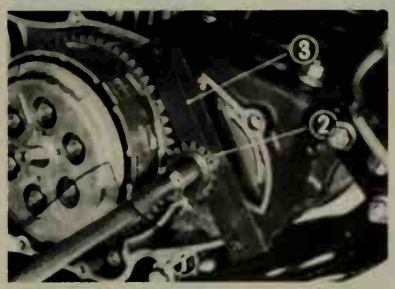
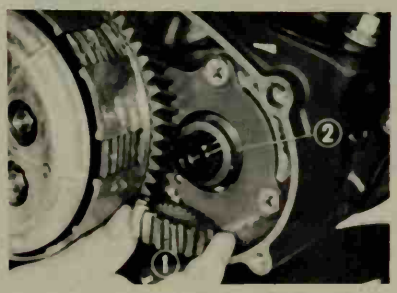
PRIMARY GEAR



All Models

NOTE: *The clutch should remain in place when removing the primary gear.*



1. Remove the right crankcase cover as described in the "Clutch" section.

2. While holding the gear from rotating with the drive gear holder (Tool No. 07924-3600000) or a suitable substitute, remove the 8 mm special bolt. If the holder is not available, the bolt can be removed by placing the transmission in gear and applying the rear brake or holding the countershaft sprocket.

3. Remove the primary gear from the crankshaft.

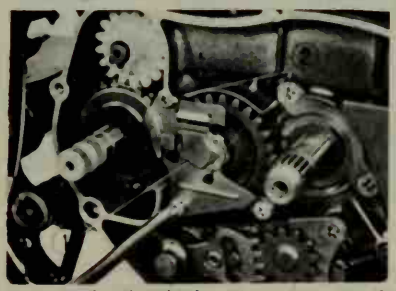
4. Installation is the reverse of the removal procedure. Torque the gear bolt to the correct specification given in the "Engine Torque Specifications" chart at the end of this section.

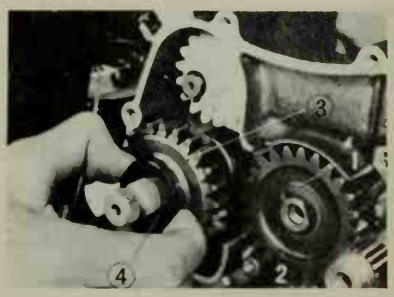
KICK-STARTER

125 and 175 Models



Removal

1. Remove the right crankcase cover and clutch as described in the "Clutch" section.



2. MT only: remove the three screws from the oil guide plate and remove the plate.

3. Remove the 15 mm snap-ring from the kick-starter idler gear and remove the idler gear.

4. Remove the 17 mm thrust washer from the starter shaft. Remove the starter ratchet gear and 22 mm thrust washer.

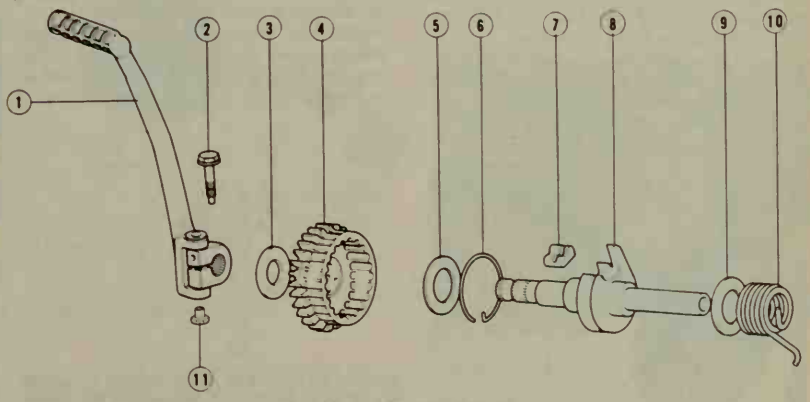
6. To remove the starter return spring or the starter shaft assembly, the crankcase halves must be split. For further disassembly refer to "Crankcase Components."



Inspection

1. Check the kick-starter pawl for chipping or wear.

2. Inspect the inside of the ratchet gear for wear and the outside for chipped or missing teeth.

3. Inspect the splines on the kick-starter shaft and the kick-starter lever; if they are damaged or torn, replace the shaft and lever.

4. Check the pawl spring retainer for weakness.

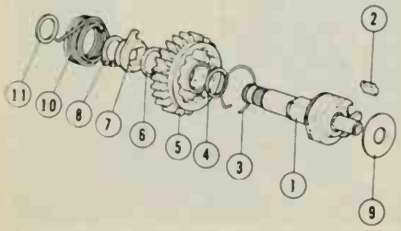
5. Check the condition of the kick-starter shaft oil seal in the crankcase cover. Replace it if it leaks or is torn or otherwise damaged.



Installation

1. Install the starter pawl into the kick-starter shaft. The round surfaces should face outward. Install the starter pawl retainer spring clip.
2. Replace the 22 mm thrust washer, ratchet gear, and 17 mm thrust washer.
3. MT models only: replace the oil guide plate and secure it with three mounting screws.

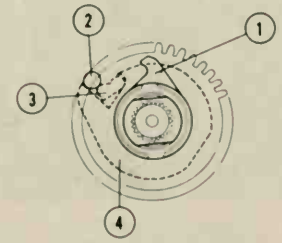
5. The kick-starter idle gear can be removed once the clutch is removed. Remove the 17 mm snap-ring and pull the idler gear from its shaft.

Inspection

1. Check the kick-starter pawl for chipping or wear. Replace if necessary.
2. Inspect the inside of the ratchet gear for wear and the outside gear for chipped or missing teeth. Replace if necessary.
3. Inspect the stopper bolt for wear; check that it is tight in the crankcase.
4. Inspect the splines on the kick-starter shaft and kick-starter lever; if they are damaged replace the shaft and lever.
5. Inspect the condition of the oil seal in the right crankcase cover. Replace with a new item if it is cracked, cut, or deformed in any way.
6. Inspect the pawl retainer for weakness; it should be a tight fit on the starter shaft.



Installation

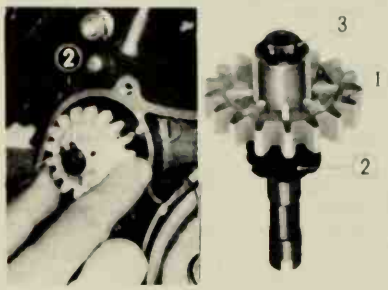
1. Place the 16 mm washer on the end of the starter shaft and install the shaft into the crankcase.
2. Install the starter pawl into the shaft and secure it with the starter pawl retainer spring.

NOTE: *When installing the pawl the curved side faces outward.*

3. Install the 22 mm thrust washer. Install the return spring retainer as shown so that the arm on the retainer faces up when the pawl rests against the stopper bolt. Secure it with the spring clip.

NOTE: *Be sure that the ratchet gear rotates when the pawl rests against the stopper bolt. This is the only position it should rotate in.*

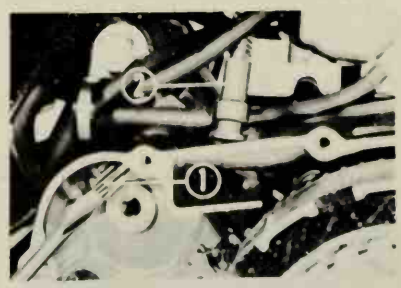
The arm on the return spring retainer (1) should face up when the pawl (3) rests against the stopper bolt (2)



4. Install the return spring and 18 mm washer.

OIL PUMP DRIVESHAFT AND TACHOMETER GEAR

MT Models



Removal

1. Remove the right crankcase cover as described in the "Clutch" removal section.
2. Remove the oil pump driveshaft; remove the 10 mm snap-ring and remove the drive gear from the driveshaft.

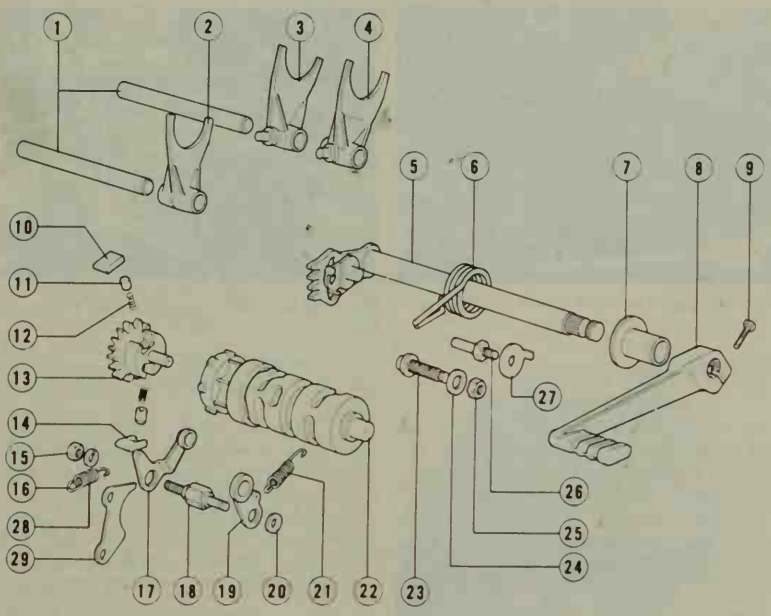
3. Disconnect the tachometer cable from the crankcase. Push the tachometer drive gear from the crankcase by pushing it out from the bottom. The oil seal, thrust washer, and tachometer gear collar will come out with the tachometer drive gear.

Removing the tachometer gear (1) from the crankcase

Inspection



1. Inspect the gear teeth for wear; replace if any are worn, chipped, or broken. Check the collar for wear. The oil seal should be replaced if damaged.

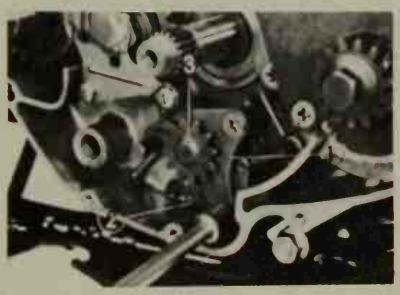
SHIFTER MECHANISM

125 Models

Removal

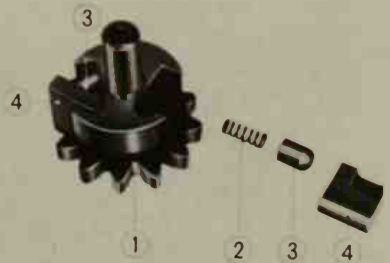
1. Remove the right crankcase cover, and clutch assembly as described in the "Clutch" section.

2. Remove the gearshift lever and pull the spindle out of the case.



Removing the shifter spindle (1)

3. Remove the shift drum stopper plate, neutral stopper, and drum shifter. When removing the drum shifter, take care not to drop the pawl plunger and plunger spring.



4. Remove the drum stopper arm collar and drum stopper arm.

Inspection

1. Clean all parts in a suitable solvent, then blow them dry. Inspect all parts for signs of damage or wear, replace them as necessary.

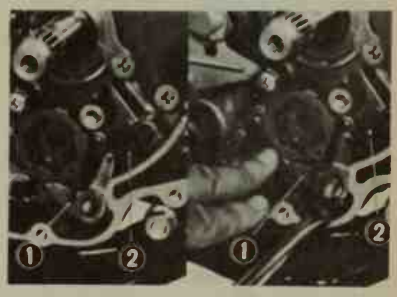
3. Check the pawl return spring for cracks, bent or deformed ends, and replace if necessary.

4. The gearshift spindle oil seal is fitted into the left crankcase half. If it leaks, pry it out with a small screwdriver and press a new seal into the case.

Installation

1. Installation is in the reverse order of removal.



2. Install the shift drum stopper spring to the drum stopper arm, then install the drum stopper arm, washer, and collar so that the longer threaded part of the collar points inward. Secure the collar while holding it steady with a screwdriver.

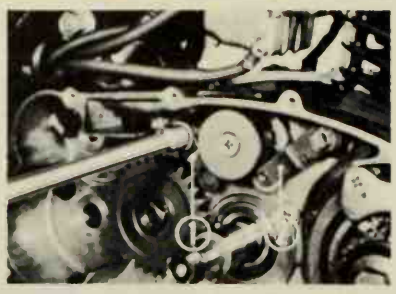
250 Models

Removal



1. Remove the right crankcase cover and clutch assembly as described in the "Clutch" section.
2. Remove the gearshift lever.
3. Disengage the gearshift arm from the shift drum and pull the shift spindle out.
4. Remove the drum stopper and the neutral stopper arms.

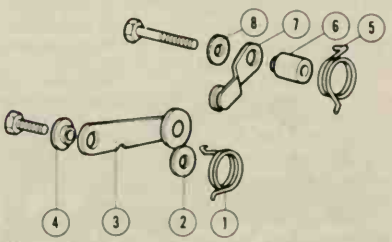
Inspection



1. Clean all parts in a suitable solvent.
2. Check all springs for a weak condition and replace as necessary. Check the pawl return spring for cracks, or bent or damaged spring ends, and replace if damaged.
3. Check the shift spindle for a bent condition, or worn or damaged splines. Check the gearshift arm. The arm must not be bent or have worn fingers.
4. The oil seal for the gearshift spindle is fitted into the left crankcase half. If it leaks, pry it out with a small screwdriver, and press a new seal into the case.

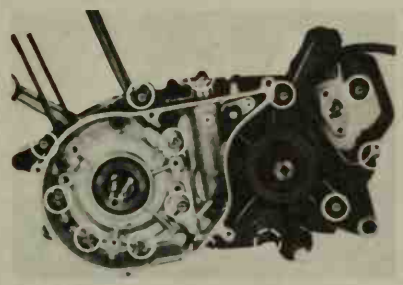
removal. Install the drum stopper arm and the neutral stopper arm as shown in the accompanying illustration.

2. After the assembly is installed, operate it by hand to check for smooth operation. If the operation is stiff, either the stopper bolts are over-torqued, or the washers and collars are not correctly positioned.

Crankcase Components

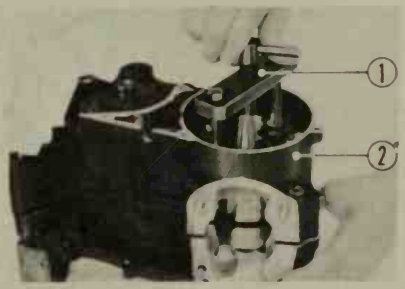
To service the crankshaft, its bearings, the transmission, and the kick-starter spindle and return spring on 125 models, the crankcases will have to be split. To do this, drain the transmission oil, remove the engine from the frame, remove the kick-start lever, gearshift lever, cylinder head, cylinder, and piston, the left and right crankcase covers, and the clutch, primary gear, oil pump driveshaft, tachometer gear, shifter mechanism kick-starter assembly, idle gear, magneto assembly, oil pump, and countershaft sprocket.

All of these operations are previously described.



A special crankcase puller, Honda Tool No. 07937-3600000 for the 125 and 175 cc models or Tool No. 07937-3570000 for the 250 models, will be necessary to pull the crankcases apart.

SPLITTING THE CRANKCASES

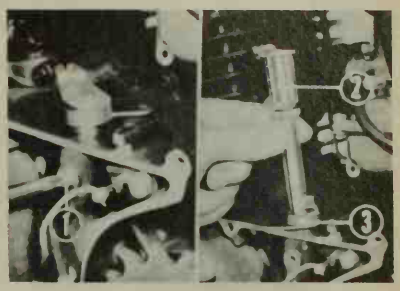


250 Models

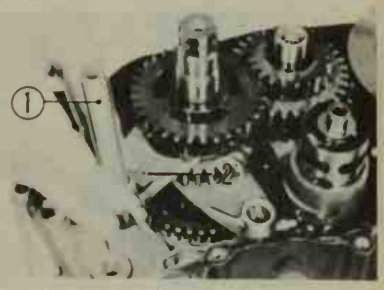
1. Assuming that the engine has been removed from the frame, and that the engine case assemblies and top end have been removed, loosen the 14 phillips head crankcase screws in a cross pattern with an impact driver. When all the screws have been loosened at least one full turn, remove them.

2. Install the crankcase puller into the two 8 mm holes tapped into the left crankcase. While screwing the puller in, tap lightly on the end of the countershaft to separate the crankcases.

Crankcase screw locations (250 models)



Splitting the crankcase with the special tool (1)

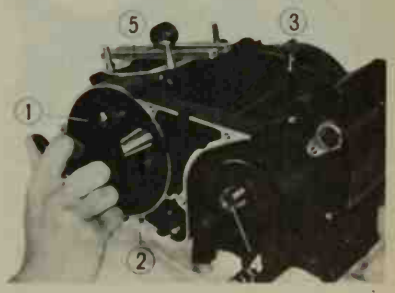


CAUTION: *Do not tap on the end of the crankshaft, this will bend the crankshaft by pinching the flywheels together. Do not attempt to pry the case halves apart as this may damage the mating surfaces.*

3. Remove the engine clutch lever by first removing the 5 mm special screw from the left crankcase, then pull the lever up and out. Remove the oil seal and the 16 mm needle bearing from the left crankcase.

4. Pull out the gearshift fork shaft and remove the left gearshift fork; now the transmission, gearshift drum, and the right and center gearshift forks can be removed as an assembly.

Removing the engine clutch lever 5 mm special screw (1), lever (2), and spring (3)

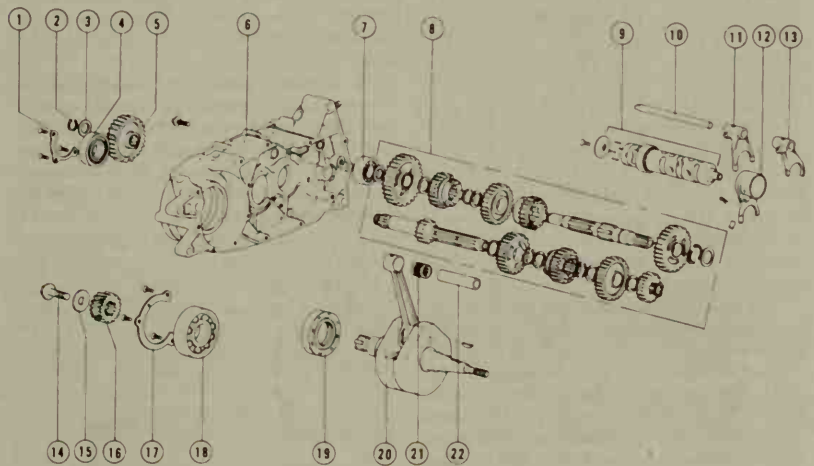


Removing the gearshift fork shaft (1) and left shift fork (2)

5. The crankshaft can be removed from the crankcase by tapping it on the end with a soft-faced mallet. Use no more force than is necessary.

125 and 175 Models

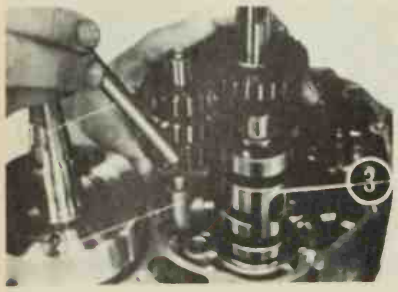
1. Assuming that the engine has been removed from the frame, and that the engine case assemblies, and top end have been removed, loosen the 13 phillips head crankcase screws in a cross pattern with an impact driver. When all of the screws have been loosened at least one full turn, remove them.



Splitting the crankcases with the special tools: crankcase puller (1) and con rod holder (2)

2. Install the crankcase puller into the stator attaching holes in the left crankcase. Screw in the puller while tapping on the end of the countershaft with a soft-faced mallet to separate the crankcases.

CAUTION: *Do not tap on the end of the crankshaft to separate the crankcases as this may bend the crankshaft by pinching the flywheels together. Do not attempt to pry the cases apart as this may damage the mating surfaces.*



3. Pull out the gearshift fork shafts and then remove the gearshift forks, and gearshift drum.

4. Remove the transmission mainshaft, and countershaft assemblies together.

6. With a soft-faced mallet tap the crankshaft out from the right crankcase as shown. Never use more force than is necessary.

CRANKCASE SERVICE

All Models

1. Remove the bearing set plates from the right crankcase.

Crankshaft and mainshaft bearing set plates (1 and 2)

2. Remove the oil seals from the crankshaft bearings with a small screwdriver or hooked tool, prying out the seals. Note that the seal in the left crankcase half is taken out from the outside of the crankcase; while the seal in the right crankcase half is reached from the inside of that case. Be very careful not to damage the crankcase surfaces while prying out the oil seals. New seals must always be used when reassembling the crankcase.

3. To remove the crankshaft bearings, use a propane torch to heat the cases in the vicinity of the bearings, but do not let the flame touch the bearings themselves. Then, drive out the bearings with a soft metal drift and hammer.

4. Clean the bearings thoroughly in a clean solvent, and then check their general condition.

CAUTION: *Never spin an unlubricated bearing in its race or cage.*

5. Place each bearing on a flat surface, holding the outer race firmly in place. Attempt to move the inner race back and forth. If it is possible to move the inner race, the bearing should be replaced with a new one.

NOTE: *The crankshaft bearings should be replaced as a set since, if one is worn, the other has probably been subjected to some stress.*

6. Make a visual inspection of each bearing, noting any obvious signs of damage or discoloration. Check the rotation of the bearings, noticing any roughness or halting movement when rotated. Any of the above symptoms would necessitate replacement of the bearing. They should also be replaced if you are in doubt as to their condition, just to be on the safe side.

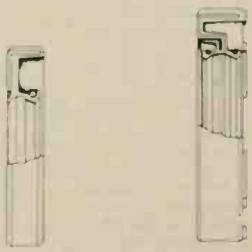
7. Remove the remaining oil seals and bearings in the same manner as described for the crankshaft oil seals and bearings. Once again, all oil seals should be replaced with new ones. Inspect these bearings as described for the crankshaft bearings, above.

8. Needle bearings are fitted to the left-side of the countershaft and to the right-side of the mainshaft on 125 and 175 cc models. These are removed in the same manner as for the crankshaft bearings. Check these bearings for loose needles, or any needles which are worn, scored, or pitted. Check that the needles rotate freely in their cage. Inspect the cage for distortion, or score marks. Replace the bearings if any of these conditions exist.

case halves themselves. It is especially important that the crankcase mating surfaces be clean and very smooth. They must be free of scrapes or scoring as might be found if improper means were used to separate the crankcase halves. The cases should be replaced if a good seal cannot be obtained.

10. Check the cases for any cracks or fractures in the areas around the bearings.

11. Check the fit of the bearings in the cases. The crankshaft bearings are critical. If the bearing surfaces on the cases are badly scored due to a spun bearing, it is advisable to replace the crankcases.



NOTE: *Crankcases are supplied in pairs.*
